Contribution to the Fehling-Soxhlet sugar determination. RUOSS. *Z. anal. Chem.* 55, 1-23(1916).—A critical review and study of methods. The volumetric methods of Soxhlet (*Z. anal. Chem.* 20, 45(1880)) and Pfleger (*Ibid* 43, 356, 364) are only applicable with sugar solns. of more than 0.5% (1-0.5), necessitating concn. by evapn. (with risk of formation of reducing products) or reinforcing by the addition of a known amt. of dextrose (cf. Schöndorff, *C. A.* 2, 3104). R. has derived from the published work of Soxhlet a mathematical equation by which the amt. of sugar can be accurately ascertained to 0.001% in solns. containing 0.1 to 1.0%. A table is given showing for the number of cc. of the sugar soln. equiv. to 100 cc. of Fehling soln.: "Fehling %" as found, and "correct %," as calcd. The use of the table and methods of calcn. are explained in detail. Below 0.1% the found and calcd. values agree to the second decimal place. The following method was devised for detg. the presence of Cu^+ ions in the boiled sugar-Soxhlet soln. without filtration: Solns. A. $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ 69.278 g. per l.; B. $\text{NaKC}_4\text{H}_4\text{O}_6$ 346 g. + 103.2 g. NaOH per l.; C. To 300 cc. of 96% AcOH add 200 cc. of H_2O and dil. to 1 l. with NaCl soln. (330 g. per l.); 300 g. of tartaric acid may be substituted for the AcOH. D. KCNS 30 g. in 100 cc.; E. $\text{K}_4\text{Fe}(\text{CN})_6$ about 10% soln. Example of titration: Heat 1 cc. A + 1 cc. B + 1.5 cc. of dextrose soln. (0.5%) to boiling in an Erlenmeyer flask, then add 2 cc. of C at once with gentle whirling; to the clear soln. add 3 drops of D and whirl vigorously. A white ppt. of CuCNS forms leaving a blue soln. if Cu^+ ions are present; now add a few drops of E (down an inclined rod) and whirl again; the color becomes brownish red (with slight whirling a brown ring forms at top of soln.). The above is repeated with varying amts. of the sugar soln. till no color change is produced on adding $\text{K}_4\text{Fe}(\text{CN})_6$. With sugar solns. of 0.1 to 1.0% sugar content the following solns. were used: a 69.278 g. $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ + 250 g. NaCl per l. Dissolve the CuSO_4 in 100 cc. H_2O and dil. with the NaCl soln. (add 1 or 2 drops of dil. H_2SO_4 or HCl if turbid); b same as B above; c 400 cc. 96% AcOH + 150 g. NaCl + 15 g. KCNS per l. To 400 cc. of AcOH add 100 cc. H_2O and 15 g. KCNS, and dil. to 1 l. with the NaCl soln.; d, 10% $\text{K}_4\text{Fe}(\text{CN})_6$ soln. Titration: Heat to boiling 1 cc. a + 1 cc. B + sugar soln., add at once 2 cc. of c and whirl vigorously, cool to about 50°, and add a few drops of d; repeat as above till no color change. If too much of c is added the Cu_2O ppt. may not dissolve, which is the case when the KCNS is mixed with b; solns. A, B, C, D, E do not have this disadvantage. Using an undild. Fehling soln., the disappearance of the blue color and the reddening with $\text{K}_4\text{Fe}(\text{CN})_6$ is sharper; the same holds if a dild. Fehling soln. is used with an undiluted sugar soln. Detn. of percentages between 0.01 and 0.1%: at least 10 mg. of NaOH or 10 mg. $\text{NaKC}_4\text{H}_4\text{O}_6$ per 1 cc. of sugar soln. must be present. The sugar soln. and soln. A must be accurately measured (a pipet of such diam. that 10 cm. = 1 cc.). The titration is made as above using following proportions: 10 cc. of sugar soln. + 1 cc. B + 1 cc. A, 2 cc. C, 3 drops D, 3 drops E. A study of the iodometric method of de Haën and Moser (*Z. anal. Chem.* 43, 597(1905); *Z. anorg. Chem.* 56, 143(1907)) showed that great accuracy can not be attained with the method as usually executed, due to the oxidation by the liberated I of substances formed on boiling sugar solns. with alk. CuSO_4 soln. (cf. Glaud, *Compt. rend.* 119, 73(1894)). A better procedure is to filter off the Cu_2O , dissolve the latter in HNO_3 , expel nitrous fumes and

det. Cu iodometrically (cf. Lehmann, *Arch. Hygiene* 30, 274 (1898)), or dissolve the Cu_2O in $\text{Fe}_2(\text{SO}_4)_3 + \text{H}_2\text{SO}_4$ and titrate with KMnO_4 . The method of Bang based on the titration of the excess of Cu^+ salt with hydroxylamine sulfate soln. is not very accurate (about of same order as the rough or preliminary Fehling detn.), results differing from those obtained by polarization by 0.7%. Pavy's method (*Z. anal. Chem.* 19, 98) has no advantage over the Soxhlet; results vary with rate of titration; working with the dil. sugar solns. required errors are multiplied tenfold; the action of the air vitiates the results. The safranin method of Lindhardt and Hasselbach (*C. A.* 5, 312) has the disadvantage of color reproduction by action of the air, a slight shaking causing uncertainty as to the results. R. concludes that the volumetric Soxhlet method and those methods in which the Cu_2O is filtered off and washed surpass all other methods for accurately detg. sugar. If nitrogenous and coloring matters are completely removed from the sugar soln. by means of $\text{Hg}(\text{NO}_3)_2$, the sugar can be more accurately detd. gravimetrically or volumetrically than by polarization or fermentation. Cf. Schöndorff, *C. A.* 2, 3104; Rupp and Lehmann, *C. A.* 3, 1185; Kinoshita, *C. A.* 2, 2566; Ruoss, *J. prakt. Chem.* 22, 60.

F. W. S.

Protection against evaporation of water in the filtration of sugar solutions which are to be polarized. J. J. WEISS. *Z. Zuckerind. Böhmen* 39, 455-6 (1915).—W. discusses the results obtained by Bates and Phelps in studying changes in concn. of sugar solns. due to a filtration before polarization. Covering the filtering funnel with a glass plate or watch glass is considered to be a sufficient precaution against evapn. during filtration. W. describes a simple filtering vessel based on this principle.

H. S. PAINE.

A juice sampling device. H. E. DEBRIAS BACHER. *Arch. Suik-erind.* 23, 888-90 (1915); see fig.—From a circular piece of sheet Cu $\frac{1}{16}$ in. thick is cut a piece consisting of a central circular disk with a number of radial T-shaped arms. In two or more of these T's a depression (m) is hammered, and then all the arms are bent at right angles to the plane of the disk. The wheel is mounted as shown in an open launder. The speed of the wheel (and hence the size of the sample) is regulated by making the baffles (p) constrict the stream to a greater or less extent.

W. L. BADGER.

A rapid picnometer method for the determination of "gravity solids." HERBERT S. WALKER. *Intern. Sugar J.* 18, 33-7 (1916).—A 100 cc. picnometer with ground-in thermometer and capillary side arm is used. Since all detns. are made at room temp., the cap to the side arm is discarded and the arm itself cut off 2 or 3 mm. above the graduation mark, thus facilitating rapid filling to a definite vol. All calcs. can be eliminated by making a picnometer to contain exactly 100 g. of H_2O at a given temp. according to the tables used. The wt. of the liquid in the picnometer would then be 100 times its d. as compared with H_2O at that temp. and if a tare were made exactly to counterpoise the empty picnometer, the wts. required to balance the picnometer filled with sugar soln. would indicate the d. of that soln. without calcn., following which the Brix reading could then be obtained from tables, applying the same correction

used for Brix spindles in case the detn. were not made at the standard temp. Directions and tables of correction are given for using picnometers of different capacities and for solns. of the same or different ds. Also in *J. Ind. Eng. Chem.* 8, 262-4(1916).

A. GROSS.

Recovery of glutamic acid and betaine from extracts of the residue remaining from the recovery of sugar from molasses. K. ANDRLEK. *Z. Zuckerind. Böhmen* 39, 387-91(1915).—A. has improved his previous method for recovery of glutamic acid by substituting crystn. from aq. solns. for crystn. from hydro-alc. solns. One kg. of concd. ext. (78° Balling) of molasses residue is gradually mixed (with const. stirring) with 140 g. concd. (98%) H_2SO_4 dild. with 200 cc. H_2O . After cooling to 55° the liquid is rapidly filtered from the pptd. K_2SO_4 and allowed to stand 18-24 hrs. The approx. 150 g. of impure glutamic acid (contaminated with K_2SO_4) which sep. during this time are treated with 300 cc. boiling H_2O and the soln. is filtered hot (most of the K_2SO_4 remains undissolved). The filtrate is decanted from the 1st crystals (K_2SO_4) which sep., glutamic acid being deposited on subsequent cooling. The glutamic acid thus obtained is recrystd. from hot H_2O , sufficient (2-3 g.) animal charcoal being used to decolorize the soln. on the last crystn.; 30 g. colorless glutamic acid crystals with 9.5% N, m. p. 201-3° and $[\alpha] = +12.04^\circ$, are thus obtained. In view of the difficulty of sepg. K_2SO_4 and glutamic acid this method was modified by using H_3PO_4 (810 g. of 40% H_3PO_4 to 1 kg. concd. ext. (78° Balling) of molasses residue) instead of H_2SO_4 , the general subsequent procedure being essentially the same; 30 g. pure glutamic acid with 9.59% N, m. p. 202.5° and $[\alpha] = +12.04^\circ$ were obtained. The method was again modified by mixing 1 kg. of the concd. ext. (78° Balling) of molasses residue with 450 g. of a 30% tartaric acid soln. After 1 hr. the liquid was filtered from pptd. K tartrate and the filtrate was concd. on a H_2O bath to approx. 15° Balling and inoculated with glutamic acid crystals. Glutamic acid sepd. in 12 hrs.; when a higher concn. was employed glutamic acid sepd. as a gel. Recrystn. from hot H_2O (decolorizing with animal charcoal on the last crystn.) yielded a total of 60 g. colorless glutamic acid crystals, this being twice the yield obtained by the previous methods. Betaine phosphate was obtained by mixing 1 kg. of the concd. ext. (78° Balling) of molasses residue with 810 g. of approx. 40% H_3PO_4 , filtering off the cryst. mass of K_2PO_4 and glutamic acid which sepd. after 48 hrs., adding 300 g. of 40% H_3PO_4 to the filtrate and concg. on a H_2O bath to a wt. of approx. 800 g. The mass of crystals (impure betaine phosphate mixed with K_2PO_4) which sepd. after 48 hrs. was fractionally recrystd. from hot H_2O , the resulting 3 fractions being finally combined, decolorized with animal charcoal, and recrystd.; pure betaine phosphate was thus obtained [yield not stated]. Pure betaine was obtained by treating 100 g. betaine phosphate (dissolved in 750 cc. warm H_2O) with approx. 20 g. $Ca(OH)_2$ (in the form of 5° Bé. milk of lime) until the reaction became alk., filtering, concg. the filtrate on a H_2O bath until crystn. ensued and recrystg. until purity was attained.

H. S. PAINE.

The presence of reducing sugars in freshly harvested sugar beets. H. PELLET. *Bull. assoc. chim. suc. dist.* 32, 59-92(1915).—A very complete summary of the work done in the past century concerning the presence or absence of reducing sugar in sugar beets, together with a report of work done in 1913-4 by P. *et al* on this subject. Analyses made in various factories in France, in Egypt, Holland, Italy, Belgium, Spain and England are recorded. P. concludes that: (1) Freshly cut beets contain from 0.04% to 0.50% of reducing sugar, most specimens containing from 0.08% to 0.05%. (2) There is no relation between the richness in sucrose and the amt. of reducing sugar. (3) The amt. of reducing sugar is practically const. throughout the period of growth. (4) Allowing beets to remain exposed to the air for several hrs. does not increase the amt. of reducing sugar. (5) Beets grown in different seasons, in different countries,

and under varying climatic conditions show varying amounts of reducing sugar. (6) That earlier investigators had not been able to find any reducing sugar was due to the lack of a delicate chem. method. The method used was as follows: Treat 100 cc. of fresh juice with 4.5-6.0 cc. $\text{Pb}(\text{OAc})_2$, make to 110 cc. and filter. Remove the Pb from 55 cc. with satd. Na_2CO_3 soln. and filter. Heat to boiling 2 cc. of freshly mixed alk. Cu tartrate soln. (1 cc. = 0.005 g. reducing sugar). Introduce the sugar soln. from a buret into the boiling soln. in 2 cc. portions, allowing the mixt. to come to a boil between each addition. (7) Fodder beets low in sucrose do not contain more reducing sugar than do sugar beets. (8) Beets stored 5 or 6 mo. under favorable conditions do not develop more than 0.18% reducing sugar.

H. R. SMITH.

The formation of sucrose in beets. H. PELLET. *Bull. assoc. chim. suc. dist.* 32 159-165(1915).—A résumé of the long-continued discussion between Peligot, Girard, Vivien, Colin, Aulard and Pellet concerning the chemistry of the formation of sucrose in beets. The following points are made: (1) There is always reducing sugar in fresh beets which is contrary to the conclusions of Peligot, Girard, and others. (2) In the beet foliage there is always present with the sucrose a considerable amt. of reducing sugar—usually 3 or 4 parts to 1 of sucrose. (3) It has been asserted by various investigators that the amt. of sucrose in the leaves diminished during the night. P. finds that in 3 separate expts. under conditions favorable for accurate observations the diminution of sucrose was small and was accompanied by a corresponding diminution in reducing sugar. (4) The root is capable of transforming the reducing sugar into sucrose without the aid of the foliage. It is evident that there is formed in the leaf during the day both reducing sugar and sucrose, and that both of these pass to the root during the night where the sucrose is stored and the reducing sugar converted to sucrose and stored.

H. R. SMITH.

Cultural methods for inducing increase of sugar in stems of maize. O. MUNERATI AND G. MEZZADROLI. *Boll. dell'assoc. ital. dell'industria dello zucchero dell'alcool* 8, 25(1915-16); through *Ann. chim. applicata* 4, 365.—Expts. carried out in the low Padano valley in 1913-14 confirm the theory of Pallas Stewart that the extirpation of immature ears and of male flowering brings about a noteworthy increase of sugar in the stems of maize. The extirpation of the ears should be done without removing the bracteal involucre, and that of the male flowerings should be continued till fecundation occurs.

Factors affecting economy in vacuum pans. E. W. KERR. *Intern. Sugar J.* 18, 24-9(1916); cf. *C. A.* 10, 130.—Tests on vacuum pans were made with a view to obtaining data regarding heat transmission and economy under regular operating conditions; different types of pans were used with varying grades of products. The av. coeff. of heat transmission in the express pan tests was 40% greater than the av. coeff. in coil pans. The rise in temp. of boiling due to hydrostatic head, d. and purity was shown to be less in an express pan than in the coil pans, which is again an advantage in that the smaller the temp. rise the greater the temp. fall for a given steam pressure and means that there is a corresponding increase in capacity.

A. GROSS.

Use of germicides in sugar mills. W. E. CROSS. *Rev. industrial agr. Tucuman*, 6, 87-9(1915).—C. discusses the expts. of W. L. Owen on the relative germicidal value of formol, chloride of lime, milk of lime, NaHSO_3 , NaF and NH_4F in sugar mill work. Cf. *C. A.* 9, 2991.

LLOYD BALDERSTON.

Destruction of anthrax spores on skins and pelts by sodium hydroxide. E. HAILER. *Arb. kais. Gesundh.* 50, 96-121(1915).—Anthrax spores in cattle skins, sheep and goat pelts are killed by 0.5-1% NaOH at a temp. of 15-20°, the toxic action of the NaOH being increased by the addition of 5-10% NaCl; nearly all spores are dead in 72 hrs. Even after treatment with NaOH and pickling a few spores may remain alive in isolated pieces of skin. Treatment of skins with NaOH before pickling has the advantage that soaking, liming and disinfecting may be done in one process. The combination of NaOH with the constituents of skins does not show a definite relation, as is the case with HCl. Extensive directions for the bacteriologic work are given, the method of Conradi being used (cf. *C. A.* 7, 355). It is shown that the wt. of dil. NaOH used should be at least 10 times that of the skins treated. L. W. RIGGS.

Pure salt for the preservation of hides. ANON. *Conceria* 22, 332(1914).—An English patent (18,890,1913 (*C. A.* 9,394)) based on the Abt theory of the inorganic origin of salt spots has recently been issued; the procedure involved requires the use of practically pure salt. According to the theory, the substance of the hide, because of its colloidal nature and amphoteric property, absorbs the salts of Mg and Ca which are present in common salt with consequent detriment to the hide and production of spots. By means of a special process it is possible to obtain common salt containing 99.99% of pure NaCl and it is claimed that when this product is used the amount of liquor which exudes from the hide is less than in cases where the impure salt is employed; the amt. of alk. substance dissolved from the hide is also reduced to a min. NaCl does not form a hydrate under the usual conditions of temp. and pressure, while the following hydrates are formed by salts which constitute the usual impurities in common salt: CaCl₂·6H₂O, MgCl₂·6H₂O, CaSO₄·2H₂O, Na₂SO₄·10H₂O. It is further claimed that the alk. substance which is formed by the action of pure salt on hides is removed by washing prior to liming, while the amount of nitrogenous material which passes into solution is reduced to a min. because of the absence of sulfates and salts which form hydrates. When impure salt is used, the above alk. substance probably reacts with salts of Ca and Mg with production of complex neutral salts and formation of insol. protein compds. The salts of Ca and Mg are further capable of reacting with the natural fatty substance (a portion of which is present in the form of free fatty acids) of the hide, thus producing insol. soaps. These soaps, being distributed irregularly in the hide, obstruct the pores, thereby producing spots, as well as a decrease in the vol. of leather which is obtainable. If the above claims are found to be justified, this

pure salt should find a wide application, provided it can be produced with sufficient cheapness.

30. RUBBER AND ALLIED SUBSTANCES.

R. T. STOKES.

A worthless guttapercha "substitute." *Utz. Pharm. Zentralhalle* 56, 481-2 (1915). —The substitute was claimed to be a pure nitrocellulose but proved to be an inferior grade of guttapercha, artificially colored.

C. O. EWING.

Chemistry of amorphous solids (LEWIS) 2.

Vulcanizing frothy tire fillers, etc. *F. FLEUMER. U. S.*, 1,167,518, Jan. 11. Balata or gutta-percha "froth fillings" for tires, etc., are vulcanized with hot gas under a pressure of 320 atm., cooled under a higher gas pressure, placed in a casing, heated to 79-90° and subjected to a vacuum to expand the filling.

Devulcanizing rubber. *G. STAUNTON. U. S.*, 1,169,437, Jan. 25. Dry ground rubber waste is mixed with dry K_2CO_3 and the dry powdery mixt. is spread in thin layers and exposed to the action of steam under 60 lbs. pressure per sq. in., or a somewhat lower pressure.

Recovering rubber from vulcanized waste. *G. STAUNTON. U. S.*, 1,168,230, Jan. 11. Comminuted vulcanized waste rubber is dried at a temp. of 110-150° with 20-25% its wt. of K_2CO_3 , and washed with H_2O and dil. acid.

Rubber substitute. *A. A. GLIDDEN. U. S.*, 1,171,187, Feb. 8. Rubber waste 30 is mixed with β,γ -dimethylerythrene 100 and with stearic acid 1 part; and heated in a sealed vessel at 100-120° for 1-3 weeks, to form a rubber substitute suitable for vulcanization.

Isoprene. *H. S. A. HOLT. U. S.*, 1,168,070, Jan. 11. The oil obtained as by-product in the manuf. of caoutchouc from 2,3-dimethyl-1,3-butadiene is distd. with steam and then vaporized and slowly passed through a tube containing an elec. heated Pt wire at a temp. of 500-700°. The distillate consists principally of 2,3-dimethyl-1,3-butadiene with small amts. of hydrocarbons of higher b. p. The oil is preferably sepd. from any unchanged residual hydrocarbon at the beginning of the process, before distg. with steam.

Waterproof fabrics. *F. E. BARROWS. Ger.*, 285,138, Oct. 26, 1912. The material to be waterproofed is treated with hydrocarbons yielding synthetic gums, such as isoprene, erythrene, diisopropenyl or other substituted erythrene, or a mixt. of these, whereupon these hydrocarbons are converted, by the known process of polymerization, into synthetic gums. A more uniform and thorough impregnation with gum is effected in this manner than is possible with the use of gum solns.

Published by the American Chemical Society, Easton, Pa.

Entered as Second-class Matter at the Post-Office, Easton, Pa.

Communications for the Editor should be addressed to E. J. Crane, Ohio State University, Columbus, Ohio.

The Council have voted that no claims for copies lost in the mails can be allowed, unless such claim is received within "sixty days" of the date of issue, nor if due to failure to give sufficient notice of change of address. Charles L. Parsons, Secretary.

Remittances for annual membership dues or for subscriptions, changes of address, orders for subscriptions or back numbers, claims for missing numbers and all matters intended for the Proceedings should be sent to the Secretary, Charles L. Parsons, Box 505, Washington, D. C.

Secretary's Office: Box 505, Washington, D. C.
Eschenbach Printing Company, Easton, Pa.

The American Chemical Society

The Board of Directors of the American Chemical Society has fixed the following schedule of prices for its publications:

Subscription Rates

Journal American Chemical Society.....	\$ 6.00
Chemical Abstracts.....	6.00
Jour. Industrial and Engineering Chemistry.....	6.00
Two Journals to same address.....	10.20
All three Journals to same address.....	12.60

Back Numbers and Volumes		To Members	To Non-members
Single Numbers: J. A. C. S.; J. I. E. Chem. or Chem. Abs....		0.50	0.60
Back volumes	Proceedings, Vol. 1 (1876); Vol. 2 (1877).....	2.00	2.50
	J. Am. Chem. Soc., Vols. 1-16 inclusive, each....	4.00	5.00
	J. Am. Chem. Soc., Vols. 17-37 inclusive, each....	5.00	6.00
	Chem. Abs., Vol. 1, 2, 3 or 5 complete, each.....	10.00	12.00
	Chem. Abs., Vol. 4, 6, 7, 8 or 9 complete, each....	5.00	6.00
Index to Vols. 1-20, J. Am. Chem. Soc.....		0.50	0.75
Index to Chem. Abstracts, Vol. 1, 2, 3, 4, 5, 6 or 7.....		1.00	1.00
Jour. Ind. and Eng. Chem., Vols. 1-7.....		5.00	6.00

Foreign Postage, each Journal 75c.; Chemical Abstracts, \$1.00 a year.

Special Discounts to Newsdealers, Libraries and Institutions of Learning

Complete sets, Vols. 1 to 35, of the Journal; Proceedings, Vols. 1 and 2, and Vols. 1 to 7 of Chemical Abstracts may be had of the Secretary.

The following numbers can be furnished only in complete sets, viz: J. Am. Chem. Soc., 17 (1895), 1 and 8; 18, 5; 19, 1; 20, 3; 22, 3.

Besides the above, the following numbers can be furnished only in complete volumes, viz: J. Am. Chem. Soc., 26, 4; 29 (1907), 4; 30 (1908), 2, 3, 4, 5, 6 and 7; 33, 3, 4 and 9; 34, 9, 10 and 11; Chemical Abstracts, 1 (1907), 3, 12, 13, 14, 15 and 16; 2 (1908), 1 and 2; 5, no numbers except 1, 4 and 6; Jour. Ind. and Eng. Chem., 1, only No. 11; 3, Nos. 3 and 12; 4, Nos. 3, 4, 5, 7 and 10; 5, No. 1.

Advance payment is required and should be made by check or money order only. Stamps not wanted.

The Council has voted that the Secretary shall honor claims for non-receipt of publications only if made within sixty days of their issue. Claimants must also directly state that the publication was not delivered at their recorded address. "Missing from files" is no proof of non-receipt.

The Society will not be responsible for loss due to change of address unless notification is received one week in advance of issue.

Members or subscribers desiring their Journals or Abstracts forwarded from an old address should always notify their Postmaster and leave necessary postage.

The names of members and subscribers, whose Journals or Chemical Abstracts cannot be delivered by the Post-Office Department, will be cut off the mailing list at once, and will not be restored until correct addresses have been furnished.

In the absence of other information, the notices of change of address received from the Post-Office Department will be considered as correct, and the mailing list changed accordingly.

All communications should be addressed to

CHARLES L. PARSONS, Secretary,
Box 505, Washington, D. C.

14. Water, Sewage and Sanitation...	1042		
15. Soils and Fertilisers.....	1049		

PATENTS

Abstracts of patents are included under the appropriate divisions of the journal: those on organic compounds, unless they pertain especially to some other division, are under Pharmaceutical Chemistry. The abstracts of U. S. patents are prepared by Earl T. Ragan, those of Canadian patents by Russell S. Smart, of Fetherstonhaugh & Smart, Ottawa (50 Queen St.), and all others by O. D. Swett. Most German patents are prepared, with permission, from the abstracts in *Chemiker-Zeitung* and Italian patents from those in *Annali di chimica applicata*. All other patents are obtained direct from the specifications.

Copies of any patent may be obtained for: United States, 5 cents, sent to the Patent Office, Washington, D. C.; French, one franc, sent to L'Imprimerie Nationale, 87 rue de Vieille du Temple, Paris; German, one mark, sent to the Patent Office, Berlin; British, eight pence, sent to Patent Office, London (extra postage outside United Kingdom); Austrian, write to the Patent Office, Vienna; Danish, write to the Patent Office, Copenhagen; Norwegian, 1 crown, Patent Office, Christiania; Swedish, 1 crown, Patent Office, Stockholm. Of Canadian patents, manuscript copies only are obtainable. They may be secured from Fetherstonhaugh & Smart, or the Commissioner of Patents direct. Estimates of cost may be obtained in advance.

In ordering a copy of a patent, the number of the patent, name of the patentee, and subject of the invention should be stated.

CHEMICAL ABSTRACTS

Vol. 10.

APRIL 20, 1916.

No. 8

I. APPARATUS.

L. C. JONES.

Conductivity cell for electro-titration. H. E. ROBBINS. Mass. Agr. Coll., Amherst. *Am. J. Sci.* 41, 249-50(1916).—The advantages sought were: robustness, free access for titrating directly into the cell, adequate mixing without the complications of mechanical stirrers, economy of material. The cell is connected by a narrow U-tube with a bulb into which the liquid can be sucked and returned, in order to mix it. The electrodes are inserted at the open top of the cell. They are supported and protected by an open-ended cylinder of glass, which allows liquid to be run in from a buret.

W. P. WHITE.

The oxide resistance thermometer. S. L. BROWN. Univ. Texas. *Phys. Rev.* 6, 499(1915).—B. points out the practical necessity of using const. current with resistance thermometers of the type described in *C. A.* 9, 1137.

W. P. WHITE.

Note on the construction of a short vacuum gage. E. KARRER. United Gas Improvement Co., Phila., Pa. *Phys. Rev.* 6, 49-52(1915).—Detailed description of a short McLeod gage with swivel joint, similar to Rheden's, and simpler than Reiff's. No data are given as to performance, and especially nothing as to leakage through the swivel joint, the great weakness of this type.

W. P. WHITE.

An electrically heated bomb furnace. D. F. CALHANE AND H. A. LAVENE. *Met. Chem. Eng.* 14, 140-3(1916).—The furnace consists of a central 1.75 in. iron pipe on which is wound a part of the heating coil, then 8 $\frac{1}{4}$ in. iron pipes to contain the tubes to be heated, and outside these a 6 in. iron pipe carrying the rest of the resistance. Alundum cement is used to insulate the wire (No. 18 nichrome ribbon $\frac{1}{8}$ in. wide) from the pipes. For 110 volts, 20 ft. of wire are wound on the inner tube and 98 ft. on the outer tube. Examples are given of the method of calcg. the radiation and hence the current input necessary to maintain a desired temp. (in this case 350-400°). Instead of the usual ballistic door to protect against explosions, a flat hinged door with any simple clamp is used, except that provision for explosions is made by cutting out a circular piece from the center and holding it in place by springs bearing against strips fastened to the edges of the door but raised in their central part. The action is similar to that of a poppet valve. Advantages claimed are: more uniform heating than with gas with less attention and no danger to other tubes in the furnace or to the operator in case of an explosion.

W. L. BADGER.

A practical apparatus for the preparation of alkyl iodides. NAGAVOSHI NAGAL. *J. Pharm. Soc. Japan* 1916, No. 407, 1-3.—The app. consists of a round-bottomed flask, a Soxhlet extractor (with syphon removed) and a return condenser. A porcelain plate is placed in the extractor and covered with a thin layer of asbestos. Alc. and yellow P are placed in the flask and I in the extractor. During the progress of the expt. the condensed alc. serves to wash the I into the flask. In the case of a higher alc. $\frac{1}{2}$ vol. Et₂O is added in order to increase the soly. of the I. Traces of alkyl iodide escaping from the condenser are collected by means of a bent tube, the end of which dips into water. Yields higher than 90% can be obtained. An abstract in German precedes the Japanese article.

H. W. DAUBY.

Apparatus for determining melting points above 270°. P. RASSFELD. *J. prakt. Chem.* 92, 467-8 (1915).—To obviate the disadvantages of the H_2SO_4 -bath, "Maquenne block" (cf. *Bull. Soc. Chim.* [3], 57, 471-4 (1903)), and Thiele "Cu block" methods (cf. *Z. anorg. Chem.* 15, 780), R. has devised a method in which a metal bath (e. g., Sn) is substituted for the metal block, using a box or crucible-shaped retaining vessel. A horizontal tube passes through 2 sides of the vessel, and has a vertical arm that passes up through the center of the bath (see fig.); the thermometer with a capillary tube (containing substance) attached is placed in this upright arm, the bulb reaching nearly to the bottom. One end of the horizontal tube is directed towards a window or other source of light. The substance in the tube darkens just before melting, and clears instantly with melting. The app. may be quickly heated, and is not subject to ready temp. changes, as is the Cu block by radiation. Cf. Muther and Tollens, *Ber.* 37, 313.

F. W. SMITHER.

The Hodges pneumatic trough. ANON. *Chem. News* 113, 61 (1916).—An app. by which a number of jars may be charged with gas quickly and easily. The jars are inverted on a table capable of rotation under water so that each may be brought in succession over the delivery tube.

F. A. HARVEY.

Acetylene generator. E. M. ROSENBLUTH. U. S., 1,173,122, Feb. 22.

Acetylene generator. H. W. JACOBS and H. H. LANNING. U. S., 1,173,430, Feb. 29.

Electrical plate condenser of phenol resin and paper. M. MEIROWSKY. U. S., 1,173,452, Feb. 29. Superposed sheets of paper treated with a synthetic phenolic resin and reinforced by metal plates are firmly compacted together by heat and pressure.

Fractional distillation. M. A. ROSANOFF. U. S., 1,171,464, Feb. 15. App. and method are specified. Const. temp. zones are utilized to obtain products of the desired compn.

Regulable stopper for a butyrometer. P. FUNKE & Co. Ger., 286,156, July 16, 1914.

Thermostat. K. WILKENS. Ger., 286,139, Oct. 24, 1914. The app. comprises 2 metals of different coeffs. of expansion, and a regulable contact screw.

Pyrometer with immersible stem. R. MARZ. Ger., 286,002, July 21, 1914. In the immersible end of a hollow quartz glass stem is arranged a short expansion member, the expansion of which actuates a second quartz glass rod member in connection with the usual indicator.

Spectrometric apparatus for determining color shades. F. SCHMIDT & HAENSCH and M. STANGE. Ger., 285,410, Jan. 20, 1914. The light coming from two spectra produced by a common source of light is reunited and compared, each for itself, whereby the light of the one spectrum serves for illuminating the shade being tested while that from the other spectrum is used for examg. the comparison shade.

Detection of gases by means of electrically preheated catalytic wire. E. HMOU. Ger., 286,042, Sept. 2, 1913. A Pt alloy is used for both the heated wire and the wire which effects the contact.

Device for preventing the escape of vapors from containers for volatile liquids. E. LEDERER. Ger., 286,123, Mar. 14, 1914.

Impregnating liquids with gases. A. HAUPT. Ger., 286,121, Dec. 11, 1913. An app. is specified.

Mixing machine. C. THOMANN. Ger., 286,105, June 17, 1913. The surface carrying the material is inclined at a suitable angle to the horizontal, and is provided with discharging devices in order that the material may be introduced, mixed and discharged without other mechanical means.

Filter with suspended asbestos as filtering medium. L. BOHLIG. Ger., 286,211, Aug. 14, 1913. The asbestos is stirred up in the liquid to be filtered and then allowed to settle upon the sieve. The sieve is supported at an angle of about 85° , is slightly convex, but lies more flatly against the side wall near the top, so that the suspended filter material is divided uniformly upon the sieve, lying lightly thereon but clinging firmly thereto. A similarly formed filter of cellulose may be superposed in order to provide a double filtration.

Electromagnetic separator. E. OPPEN. Ger., 296,207, Oct. 6, 1912. Different zones of increasing strength of magnetic field are arranged in the direction of flow of the material under treatment.

Furnace for manufacturing chemical or metallurgical products under pressure. E. BARTHELMESS. Ger., 286,136, July 27, 1913. The reaction chamber consists of a heat-insulated vessel constructed to withstand high pressure and adapted to be rotated around its axis in order to secure movement of the charge and uniform heating.

Tube burner for heating purposes. J. H. ACKROYD. Ger., 285,988, Nov. 7, 1913.

Burner jet for inverted lamps. AUTOGEN-WERKE FÜR AUTOGENE SCHWEISS-METHODEN. Ger., 285,577, Nov. 15, 1913.

2. GENERAL AND PHYSICAL CHEMISTRY.

WILLIAM D. HARKINS AND E. B. MILLARD.

Atomic weight of bismuth. W. OECHSNER DE CONINCK AND GERARD. *Compt. rend.* 162, 252(1916).—Bi, purified from S and As, was melted under KNO_3 , then changed to chloride and reduced to metal with H which had been passed through warm KMnO_4 soln., concd. NaOH and H_2SO_4 . From the weights of chloride and Bi the at. wt. was calcd. Only 4 detns. have been made, using each time about 0.5 g. BiCl_3 , and weighing to 4 places. The at. wts. were 208.55, 208.52, 208.48, 208.46, mean 208.50. (The value for 1916 is 208.0.) No other details of purification, methods of experimentation or weighing have been given.

E. B. MILLARD.

Some physical properties of elements and simple compounds. W. HERZ. Breslau. *Z. anorg. allgem. Chem.* 94, 1-22(1916).—A collection of data in regard to a number of physical properties which vary in harmony with the periodic system. Contains neither new material nor a new point of view.

GEORGE W. MOREY.

The relation between the boiling point and the constitution. L. CASALE. *Gazz. chim. ital.* 45, I, 567-79(1915); see C. A. 10, 301.

E. J. WITZEMANN.

The second virial coefficient for rigid spherical molecules whose mutual attraction is equivalent to that of a quadruplet placed at its center. W. H. KESOM. Leiden. *Proc. Akad. Wetenschappen* 18, 636-46(1916).—Previously the 2nd virial coeff. (B) in the equation of state was derived for rigid spheres of concentric structure whose mutual attraction is equiv. to that of a couplet placed at the center. Recent work has made it evident that the mol. of diatomic gases does not possess such a moment, and in the present paper an expression for B in terms of $1/T$ is developed on the assumption that the mutual attraction is equiv. to a quadruplet composed of 2 doublets whose axes lie in the same line and have opposite directions. Above $0.75 T_{\text{inv}}$ (the temp.

of inversion for small d .) the values of B obtained nearly coincide with that calcd. on the previous basis of attraction equiv. to a doublet, and neither differs much from those derived by means of the assumptions of Clausius and Berthelot; values calcd. on the basis of van der Waals' equation are lower. The values of B detd. for H from -100° to $+100^\circ$ are represented with sufficient accuracy by the theoretical equation.

GEORGE W. MOREY.

Two theorems concerning the second virial coefficient for rigid spherical molecules which besides collisional forces only exert Coulomb-forces and for which the total charge of the active agent is zero. W. H. Keesom. Leiden. *Proc. Akad. Wetenschappen* 18, 868-71 (1916).—K. previously developed (cf. *C. A.* 8, 1046) an expression for the 2nd virial coeff. (B) in terms of $1/T$ for rigid spherical mols. which carry a doublet at the center, in which terms containing odd powers of $1/T$ did not appear; recently (cf. preceding abstract) a similar expression was developed for the case that the mols. carry a quadruplet, and in it the term $1/T$ did not appear, but the higher odd inverse powers of $1/T$ do occur. In this paper it is shown that if the term $1/T$ does not occur the following conditions must be fulfilled: (1) the mols. behave in their collisions as rigid spheres; (2) the attractive or repulsive forces between mols. originate from a fixed point in the center, and follow the inverse-square law, so that these forces might be ascribed to an elec. agent; (3) the total quantity of the above agent in each mol. = 0 (the mols. behave as if electrically neutral). If no odd powers of $1/T$ occur, the following additional condition must be fulfilled: (4) the mol. possesses, as regards its attractive and repulsive forces, at least "1 axis of inverse symmetry," i. e., each vol. element contains a quantity of the above agent equal and opposite to that of the vol. element with which it coincides after a revolution through an angle of $2\pi/k$, k being a whole even number. If the 1st set of conditions holds true, Berthelot's equation of state will hold for high temp. at d . for which only collisions between 2 mols. have to be considered; if condition 4 is fulfilled the agreement will be better. G. W. M.

Critical end points in ternary systems. A. Smits. Amsterdam. *Proc. Akad. Wetenschappen* 18, 793-807 (1916).—A continuation of S.'s theoretical treatment of critical end points in ternary systems (cf. *C. A.* 7, 3694). The following cases are treated: (7) component A does not give crit. end points with either B or C , but does with the ternary compd. D ; (8) the ternary compd. D , decomposes into the binary compd. D , before the 2nd crit. end point q is reached; (9) in addition to the conditions given in (8), crit. end points are also found in the system $A-C$; (10) A and B both volatile, but neither give crit. end points with C , although they do with the compd. D ; (11) similar to (10) except that crit. end points occur in the system $A-C$; (12) all 3 components are volatile, but form a ternary compd., melting at a high temp., and yielding crit. end points with each of the 3 components. In each of the above cases the relations are discussed by means of projections on the basal triangle; in addition the sequence of $P-T$ curves around an invariant point is discussed, the conclusions reached being identical with those reached by Schreinemakers (cf. *C. A.* 10, 307). Projections of the 4-phase lines on the $P-T$ plane for certain systems are also drawn. G. W. M.

Investigation of the equilibrium liquid-vapor of the system argon-nitrogen. G. HOLST AND L. HAMBURGER. Eindhoven. *Proc. Akad. Wetenschappen* 18, 872-94 (1916).—An investigation of the compn. of coexisting liquid and vapor phases as a function of temp. and pressure of the system $A-N$, undertaken with reference to the technical sepn. of the 2 gases. Analyses of $A-N$ mixts. were made by fixing the N by means of a glow discharge in K vapor; the method was accurate to 0.1%, and is capable of higher accuracy. Comparison of results obtained by the above method and with a baroscope gave systematic differences when the value 0.0017809 was used for the normal d . of A , but when Schultze's value 0.00178376 was used these differences

disappeared; this value is confirmed by a preliminary expt. which gave 0.001783 for the d. of A. The methods used in the investigation were those of Onnes and his co-workers. The end points of condensation and the points of beginning condensation were detd. to 0.02°. The results obtained are presented in tables and curves, but cannot be briefly abstracted. The triple point of A is at 83.81°, 521.4 mm.

GEORGE W. MOREY.

Invariant, monovariant, and divariant equilibria. III. F. A. H. SCHREINEMAKERS. Leiden. *Proc. Akad. Wetenschappen* 18, 820-8 (1916); cf. *C. A.* 9, 2728; 10, 307.—Continuation of S.'s theoretical study of the sequence of the curves and regions representing the mono- and divariant equil. which may proceed from an invariant point in a P - T diagram, the present discussion being confined to quaternary systems. The method of derivation does not lend itself to abstracting; it is similar to that of previous papers, and to that used by S. in the discussion of the same problem in ternary systems in "Die Heterogenen Gleichgewichte." In the present case, on the basis of the shape of the solid figure formed by the points representing the compn. of the 6 phases (when the 4 components are represented as usual by a tetrahedron) the possible cases are referred to 4 types, which are all in accordance with each other in that in each the 6 monovariant curves succeed each other in the same definite succession.

GEORGE W. MOREY.

Effect of general mechanical stress on the temperature of transition of two phases, with a discussion of plasticity. P. W. BRIDGMAN. *Phys. Rev.* 7, 215-23 (1916); cf. *C. A.* 9, 2479, 2617, 3000; 10, 710.—The question at issue was: what is the effect on a transition (or melting) point of unknown extra stresses not hydrostatic in nature? A thermodynamic formula has been derived for the general case, and some special cases of it have been discussed. It was shown that if a liquid and solid are in equil., and a change dp , supposedly equal on both phases, be applied, but if on account of some imperfection of the app. an additional stress not hydrostatic was applied to some portion of the surface of equil., the melting or freezing would take place at the free surfaces with such changes of vol. as would tend to produce throughout the mass just that change of hydrostatic pressure which was supposed to have been applied. In the case of 2 solids in equil. this re-distribution of stress might not take place, on account of a protective coating of one solid over portions of the other. Objections are raised to the ordinary theory of plasticity on the grounds that plastic flow of a well annealed metal begins at the same numerical value of stress whether in compression or tension, while the theory demands that the m. p. be raised, and that there should, therefore, be no plastic flow at all under tension. B. modifies the theory so as to state that a solid subjected to any stress whatever experiences a *depression* of the m. p. at the *unstressed* surface (or at a surface stressed by less than the average amount) and melting will take place at that surface if the stress is high enough. Thus, flow is produced by a condition of actual local melting followed by regelation with equalization of pressure on all the grains. This theory is then discussed. Values of the flow point calcd. by Johnston (*C. A.* 6, 560, 1873) are from 8 to 40 times too low, when compared with the exptl. values of Faust and Tammann (*C. A.* 5, 233).

E. B. MILLARD.

Diffusion of electrolytes in gelatin. B. L. VANZETTI. *Atti r. ist. veneto* 73, II, 1385-1408; 74, II, 805-11, 1229-33. I and II. See *C. A.* 9, 406. III.—V. has carried out expts. in single tubes 2-3 mm. in diameter filled with gelatin containing AgNO_3 , into which equiv. solns. of HCl and KCl were allowed to diffuse. It was found that the relation (h'/h) between the height (h') reached by the ppt. of AgCl formed from the acid and that (h) from the salt is a constant. It was also shown that, during the same interval of time, the salt and the acid diffuse at about the same speed through gelatin containing AgNO_3 at low concns. IV. A series of expts. was carried out to det. the concn. which HCl and KCl reach at various intervals of time in diffusing through

pure gelatin. A 0.1 *N* soln. of the electrolyte was allowed to diffuse through 10% gelatin in a tube of 15 mm. diameter. Portions of the gelatin were removed at intervals and analyzed. The value of the relation h/q (height reached/quantity diffused) is const., as is also $h/\sqrt{\text{time}}$. When the concn. of AgNO_3 is fixed and that of the electrolytes diffusing in is varied, the difference in speed of diffusion of the salt and acid is explained on the basis that with low concn. of KCl there is retardation in the sepn. of solid AgCl , this latter tending to remain in the colloidal condition, whereas with HCl pptn. occurs and the acid diffuses through more rapidly than the salt. This is independent of the counter-diffusion of the Ag salt. L. T. FAIRHALL.

Adsorption. V. G. C. SCHMIDT AND B. HINTELER. Münster. *Z. physik. Chem.* 91, 103-23 (1916); cf. *C. A.* 7, 2879 (1913).—The adsorption of the vapors of C_6H_6 , C_6H_{14} , CS_2 , CHCl_3 , Me_2CO , EtOH , MeOH and H_2O by charcoal has been studied. The satn., in the case of normal liquids, is approx. inversely proportional to the mol. vol. in the liquid condition. In the case of associated liquids, the product of the satn. and the mol. vol. is sometimes larger and sometimes smaller than in the case of normal liquids. The satn. is expressed by the formula, $c_1 = kc_2^\alpha$ or $\pi(c_1/S)^\alpha$, where c_1 is the concn., c_2 the quantity adsorbed, π the vapor tension, S the satn., k and α are consts. H. JERMAIN CREIGHTON.

Theory of adsorption. IRVING LANGMUIR. *Phys. Rev.* 6, 79-80 (1915).—The valency of an atom appears to be divided among several surrounding atoms. There is thus an unbalanced force on the surface of a crystal, so that the atoms may be considered in an unsatd. state. An adsorbed film consists of atoms (or mols.) of the adsorbed material chem. held by the atoms of the solid so as to form a continuation of the space lattice of the solid. The amount of material adsorbed depends upon a kinetic equil. between the rate of condensation and the rate of evapn. from the surface. Practically every mol. striking the surface condenses (independently of the temp.). The rate of evapn. depends upon the temp. (van't Hoff's equation) and is proportional to the fraction of the surface covered by the adsorbed material. Mols. striking a surface already covered also condense, but usually evap. much more rapidly than from the first layer. Hence, except when the vapor is nearly satd., the amt. of material adsorbed on a plane surface rarely exceeds that contained in a layer one atom (or mol.) deep. The theory seems to be in quant. accord with observed effects. E. B. MILLARD.

Adsorption. TADEUSZ. *Elektrochem. Z.* 22, 176 (1916).—Polemical. Williams' work (cf. *C. A.* 8, 2093) on negative adsorption is criticized as differing in many points from the findings of T., who holds that the cond. measurements alone do not give a correct idea of the course of the C adsorption. T.'s expts. on the adsorption of $\text{K}_2\text{Cr}_2\text{O}_7$ have shown that the adsorption of K is much weaker than that of Cr_2O_7 . This is also confirmed by the work of others. It is becoming more generally believed that C adsorption is a displacement adsorption. He has also found that even the purest C, with a KCl soln., always gave off small amts. of NH_4 ions. W. E. RUDER.

Law of solubility. H. LECHATELIER. *Compt. rend.* 162, 245-6 (1916).—Polemical. Cf. A. Colson, *C. A.* 10, 304, 415, 711. E. B. MILLARD.

Chemical activity of the ions of hydrochloric acid determined by electromotive force measurements. Preliminary paper. J. H. ELLIS. Mass. Inst. Tech. *Proc. Nat. Acad. Sci.* 2, 83-7 (1916).—The e. m. f. and free energy decrease of HCl solns. of different concns. have been measured at 18°, 25° and 35°. The activity coeffs. of the solns. have been calcd. at 18°, on the assumption that at the smallest concn. (0.00167 *M*) the activity coeff. is equal to the ionization coeff. derived from the ratio of the equiv. cond. at that concn. to that at infinite diln. The values obtained show that the activity coeff. first falls more rapidly than the cond. ratio. H. JERMAIN CREIGHTON.

The dissociation and formation of sulfuryl chloride. M. TRAUTZ. *Chem. Ztg.* 39, 100(1915).—Between 18° and 100° the reversible reaction, $\text{SO}_2 + \text{Cl}_2 \rightleftharpoons \text{SO}_2\text{Cl}_2$, could not be maintained as a pure gas reaction without exposure to light; only on the addition of animal charcoal could reproducible results be obtained. The reaction in either direction then behaved as an absorption reaction, without any disturbing effect due to diffusion. The order of the reaction was roughly normal in either direction, but more exactly so in the case of the dissociation than in the case of the formation. The formation was almost independent of temp.; the dissociation had a temp. coeff. of about 1.5. These and other observations could all be explained by the restricted sphere of the reaction (confined to the absorption layer), as compared with a normal gas reaction. The formation of SO_2Cl_2 under the influence of the light of the quartz and "uvioi" lamp was studied at 18° and 99° at various concns. At the higher temp. it took place fairly normally as a reaction of the second order. The accumulation of by-products both in this reaction and, after a time, in the reversible reaction in the dark, has a disturbing effect on the constants. The dissociation under the action of light gave no constants at all on this account. The velocity of formation of SO_2Cl_2 in light was almost independent of temp. and in that respect normal. The velocities of the reaction in presence of charcoal and in presence of light were of a similar order of magnitude.

L. T. FAIRHALL.

The recognition of complexes in solution by the electrical conductivity method. C. SANDONNINI. Univ. Padoa. *Atti r. ist. Veneto* 74, 519-34(1915).—The detn. of the elec. cond. of mixts. of electrolytes has been largely used as a method of detg. the existence of complexes in soln. The theoretical and experimental material on this subject is very abundant and 2 methods have been principally used. (1) The detn. of the cond. of a mixt. of solns. of the simple salts in suitable concns. and in mol. ratios such as correspond to the compn. of the supposed complex, to see if such cond. is equal to or different from that calcd. additively. If a lower value is found, it is concluded that a complex is formed. (2) The isotherms of cond. are constructed to see if the formation of complexes is disclosed by the appearance of particular points corresponding to their concn. Much of the work that has been done is reviewed and a bibliography is given. The principal purpose of the present expts. was to det. whether the cond. curves of pairs which are known to give compds. are characteristic. The cond. was detd. at 25° in the Kohlrausch app. Rather concd. solns. of the pure salts were made which were mixed in the requisite proportions and dild. to the desired extent. *Pairs of salts that do not give complexes.* As a type of salts having nearly equal dissociation values KCl and NaCl (Noyes and Falk, *C. A.* 6, 1562) were taken. For the same reason BaCl_2 and SrCl_2 were taken. The % variations from the calcd. value for both mixts. are small and though they agree very well with the calcd. values the observed values are always a little low. As a type mixt. in which the 2 salts have a differing degree of dissociation $\text{NaCl} + \text{Na}_2\text{SO}_4$ was taken for which the data show a max. difference of -2.2% as compared with the calcd. values. *Pairs of salts that give complexes.* As types of compds. known to form complexes mixts. of $\text{KCl} + \text{HgCl}_2$ and $\text{NaCl} + \text{HgCl}_2$ were studied which are known to give $\text{KCl}_2\text{HgCl}_2 \cdot 2\text{H}_2\text{O}$ and $2\text{KCl} \cdot \text{HgCl}_2 \cdot \text{H}_2\text{O}$ (Foote, Levy, *Am. Chem. J.* 53, 239(1906)) and $\text{NaCl} \cdot \text{HgCl}_2 \cdot 2\text{H}_2\text{O}$. With the pair $\text{KCl} \cdot \text{HgCl}_2$ 11 mixts. gave a max. difference of -7.0% at 5 mol. % KCl. For the pair $\text{NaCl} \cdot \text{HgCl}_2$ the max. difference of -7.3% was observed with 10 mol. % NaCl. With $\text{KCl} + \text{CdCl}_2$ (forms $4\text{KCl} \cdot \text{CdCl}_2$ and $\text{KCl} \cdot \text{CdCl}_2 \cdot \text{H}_2\text{O}$) according to Sudhaus (*C. A.* 8, 1714) the max. differences of -8.2% was obtained at 25 mol. % KCl. Such deviations were also found by Jones and Ota (*Am. Chem. J.* 22, 11(1899)) and Lindsay (*Am. Chem. J.* 25, 64(1901)). For the mixt. $\text{KCl} + \text{CdI}_2$ Jones and Caldwell found great deviations as compared with calcd. values. Cqpd. detns. on solns.

of $v = 2.8$ and 32 equivs. per l. showed a max. difference at 25 mol. % KI in the more concd. soln. and at 40 mol. % for the soln. $v = 8$ and at 25 mol. % for the soln. $v = 32$. The curve plotted for these values shows no break corresponding to the complex but simply a convexity in the cond. curve. This coincides with the result of Woitaszewsky. In fact the presence of a sharp break in a curve of this type appears to be possible only when the 2 components combine to give a perfect complex that is itself practically not dissociated into its components as in the complex acids studied by Miotati. If, however, the complex is dissociated not only into its ions but also to a large extent into the single salts of which it is composed then the break will naturally be more and more rounding the more extensive is this dissociation, but the cond. will always be less than the calcd. values. But this convexity is not characteristic since it is also shown by mixts. in which complex formation is known to be absent. Thus from the absence of breaks in such curves one cannot conclude that complexes do not exist. The % differences between the observed and the calcd. values are greater in cases in which salts combine but this would only be qualitative evidence of the existence of such compds. and fails to indicate their exact compn. The results show that complexes in soln. are in part dissociated into their components. The results obtained by Costacescu and Apostoi may be due to error in expts. E. J. W.

The viscosity of liquefied gases. I. The rotational oscillations of a sphere in a viscous liquid. J. E. VERSCHAFFELT. Leiden. *Proc. Akad. Wetenschappen* 18, 840-56(1916).—A mathematical discussion of the relation between the time of vibration of a sphere rotating in a liquid and the viscosity of the liquid; it is preliminary to the study of the viscosity of liquefied gases. The general cases discussed are: (1) the liquid is externally unlimited, (2) the liquid is limited by a stationary concentric spherical surface. From the relations obtained (they cannot be briefly abstracted) the most favorable exptl. conditions are discussed, and an example of the application given. The general subject is given a rigid mathematical discussion, and the expts. and equations of others considered and criticized. II. Similarity of the oscillations of spheres in viscous liquids. *Ibid* 860-7.—A study of the conditions that must be fulfilled if 2 spheres, swinging in 2 different liquids, are to have "similar" motion. It is concluded that "the radius of the 2nd sphere may even be chosen arbitrarily, but the moment of inertia of the vibrating system (K) and the rotational moment (M) are then completely detd. That there is no similarity in general is due to the fact that the motion depends on 5 quantities, η , μ (viscosity and density of the liquid, resp.), R (radius), K and M ." GEORGE W. MOREY.

Relation between surface tension and other quantities. MASAO KATAYAMA. *Sci. Reports Tohoku Imp. Univ.* [1] 4, 373-91(1916).—A formula has been derived for the surface energy of liquids which is independent of the influence of the vapor above the liquid, $E = \gamma(M/(D_l - D_g))^{1/2} = a(T_k - T)$, where γ is the surface tension, M the mol. wt., D_l the d. of the liquid, D_g the vapor d., T_k the abs. crit. temp., T the temp. at which γ and the mol. vol. are detd., and a a const. This equation has been applied to calcs. of the data of Ramsay and Shields on C_6H_6 , C_6H_5Cl , CCl_4 , Et_2O , $EtOAc$ and $MeCOOH$. If the difference between the d. of liquid and vapor is used in calcg. values from the Eötvös equation, no contradiction is found between the equation and the theory of corresponding states, and the calcd. values agree with the exptl., even at temps. near the crit. temp. When the liquid under consideration is associated, the temp. coeff. of its mol. surface energy may be greater or less than the normal value of a , and the degree of association cannot, therefore, be detd. in this way. Van der Waals' equation for surface tension is also discussed mathematically. It is confirmed by expts. From it and the modified Eötvös equation (above) the following expression may be derived: $D_l - D_g = 3.03(1 - \theta)^{0.361} D_h$. A relation

exists between the Röntgen const. (σ) and that of the van der Waals' equation. The following relation between the temp. coeff. of surface tension and the Celsius temp. scale was obtained: $(1/\gamma_0)(d\gamma/dT) = B[1 - (t/t_h)]^{B-1}$, where $B = 1.234$, and the simple relation between the total surface energy and the free surface energy $\sigma/\gamma = (1 + 0.234\theta)/(1 - \theta)$ was derived and confirmed by the exptl. data. A math. discussion of total surface energy is also given. E. B. MILLARD.

A method of measuring surface tension and angles of contact. A. ANDERSON AND J. E. BOWEN. Univ. College, Galway. *Phil. Mag.* 31, 143-8 (1916).—The method depends on the measurement by optical means of the radius of curvature of the meniscus in a tube immersed in a vessel of the liquid, and of the height of the center of curvature above or below the surface of the liquid outside. To det. the radius a microscope is used, measuring the distances of an object and its image from the center of the meniscus.

G. L. WENDT.

The kinetics of the accelerated oxidation of phenylthiourea by charcoal. H. FREUNDLICH AND A. BJERCKE. Braunschweig. *Z. physik. Chem.* 91, 1-45 (1916).—The decompn. of phenylthiourea by animal charcoal consists in its oxidation by O_2 with the formation of free S and an org. base. This latter substance is in all probability the so-called Hector base. The process probably occurs in accordance with the equation: $2SC(NH_2)NPh + O_2 = PhN:C.NH.C(:NH).NPh.S + 2H_2O + S$.

The progress of the reaction with time is expressed by the equation: $k = v_0(x + \xi)^2/2m_0t\sqrt{(O_2)_L}$; where x is the decrease in the phenylthiourea concn., t the time, m_0 the original quantity of charcoal, v_0 the initial volume, $(O_2)_L$ the concn. of the O_2 in the soln., and ξ the decrease in the concn. of phenylthiourea which occurs while adsorption takes place. The velocity of the process is, therefore, independent of the concn. of the phenylthiourea, proportional to the square root of the O_2 concn., proportional to the ratio m_0/v_0 and inversely proportional to the quantity of phenylthiourea transformed, calcd. per unit weight of charcoal. The temp. coeff. is fairly large, $k_{35^\circ}/k_{25^\circ} = 2.3$. The kinetic progress of the reaction may be explained on the assumption that the process is one of diffusion, in which the strongly adsorbable phenylthiourea is always present in excess at the surface of the charcoal, while the O_2 diffuses through it. The magnitude of the temp. coeff. confirms this conception, since the equil. const. is not only proportional to the diffusion const., but is also dependent upon other quantities influenced by temp., such as the soly. of the O_2 in the diffusion layer. The adsorption of phenylthiourea by animal charcoal takes place in accordance with the usual adsorption isotherm. The adsorption decreases with increase in temp. It is shown that the progress of the oxidation of $(CO_2H)_2$ by animal charcoal (cf. Warburg, *C. A.* 8, 1437) may be regarded as a diffusion process. In support of this conception, it is pointed out that the retardation of the reaction by urethans is proportional to the quantity adsorbed, and that their influence increases in the homologous series, in conformity with the Traube rule. The equation given above agrees within wide limits with the Schütz rule, for many enzyme reactions. If the O_2 concn. is regarded as remaining const. during the expt. and v_0 as const. for the enzyme reaction, then the foregoing equation can be written in the form: $(x + \xi)^2 = n.m_0t$. However, according to the Schütz rule: the quantity of the reacting substance transformed is independent of its concn., proportional to the square root of the quantity of enzyme and to the time. It is merely necessary, therefore, to put the quantity of enzyme equal to the quantity of charcoal.

H. JERMAIN CREIGHTON.

The dynamics of the splitting off of carbon dioxide from organic compounds. E. BAUR AND R. ORTHNER. Zürich. *Z. physik. Chem.* 91, 75-102 (1916).—The decompn. of the basic ferric oxalate of Eder into ferrous oxalate and CO_2 has been mea-

sured at temps. between 160 and 200°. It has been found that an equil. is established. Attempts to convert ferrous oxalate to ferric oxalate with CO₂ have not been successful. The value 2.7×10^{-4} has been found for the equil. const. for the decompn. of salicylic acid into phenol and CO₂ at 203°. It has not been possible to synthesize salicylic acid from phenol and CO₂. The dissociation pressure of the CO₂ produced by the decompn. of Na salicylate is 183.5 mm. at 230° and 143 mm. at 220°. H. J. C.

Measurement of very low temperatures. XXVI. The vapor pressure of oxygen and nitrogen according to the pressure measurements of v. Siemens and the temperature determinations of Kammerlingh Onnes. G. HOLST. Leiden. *Proc. Akad. Wetenschappen* 18, 829-39(1916).—A discussion of the temp. scale of the Leiden Physical Lab. which seems to be about 0.05° lower than that of the Reichsanstalt, at the f. p. of Hg, though over the rest of the range considered (up to 0°) the max. difference between the two is 0.02°. The results of v. Siemens (cf. *C. A.* 8, 608) on the v. p. of O and N are recalcd. to the present temp. scale. G. W. MOREY.

Experimental technics of calorimetric measurements at high temperatures. S. TAMARU. Tokio. *J. Soc. Chem. Ind.* 35, 81-8(1916).—This paper deals only with gas calorimetry, and is an improved repetition of the German paper on the heat of formation of NH₃ (*C. A.* 9, 2619), with additional details as to exptl. procedure, especially in the measurement of the gas flow. A form of reducing valve, or gas pressure regulator, is also described, in which the valve is opened and closed by the falling or rising of a floating bell, the gas beneath which is in communication with the gas stream whose pressure is to be regulated. The bell obviously tends to rise and fall very greatly with small changes of pressure, so that the arrangement is very sensitive, but no data of its performance are given. W. P. WHITE.

The true temperature scale for tungsten and its emissive powers at incandescent temperatures. A. G. WORTHING. Nela Lab., Cleveland, O. *J. Franklin Inst.* 181, 417-8(1916).—A hollow W filament, with small holes revealing the interior, served as the black body, whose radiation was compared (using a few corrections) with that of the exterior surface. The radiation coming normally from a W surface is 0.467 times that from a black body at 1200° K. and 0.406 at 3200° K., varying linearly between the two. The corresponding differences in degrees (red light) are 33° and 375° between the true temp. of the W, and the "effective" temp., i. e., the temp. obtained by considering it to radiate as a black body. The m. p. is placed at 3630° K. W. P. WHITE.

"Color temperature" scales for tungsten and carbon. E. P. HYDE, F. E. CADY AND W. E. FORSYTHE. Nela Lab., Cleveland. *J. Franklin Inst.* 181, 418-20(1916).—The "color temperature" of a body is the temp. for which, in the radiation of a black body, 2 selected wave lengths have the same ratio of intensity as the same 2 wave lengths in the body investigated. This "color" temp. is above the true temp. of the body, and much closer to it than the effective temp. or the (lower) temp. at which the total radiation from a black body equals that from the other. This color temp. scale "accurately and very readily" defines the temp. of radiating W. W. P. WHITE.

The effective wave length of transmission of red pyrometer glasses and other notes on optical pyrometry. E. P. HYDE, F. E. CADY AND W. E. FORSYTHE. Nela Lab., Cleveland, O. *Phys. Rev.* 6, 70-5(1915).—Pyrometer glasses are not strictly monochromatic, but the theory relates to monochromatic radiations. It is, therefore, necessary to find the effective, or equiv., wave length of the glass used. The effective wave length has been incorrectly defined and measured. It is the wave length such that the ratio of the total transmission at 2 temps. is the same as the ratio of the intensities of that wave length at the 2 temps. This was measured by 3 methods, with a black body as source, for a sample "probably" of Jena "Rotfilter" glass, Na

F 4512. The effective wave length varied from 665μ for $1336-1600^\circ \text{K.}$ to 0.662μ for $2400-3100^\circ$. Other glasses can easily be compared with this carefully calibrated glass. It was also found that the transmission changes with the temp. of the glass, falling, for 0.65μ , to less than half between 20 and 80° . W. P. WHITE.

The movement of ions (and electrons) in an electric and magnetic field. A. RIGHI. *Ann. phys.* 4, 229-70(1915).—R. discusses the movement of ions and electrons in elec. and magnetic fields from a math. standpoint. In the cases of electrolytes and gases, a few expts. of a qual. nature are included. L. T. FAIRHALL.

Mechanical strain and thermoelectric power. W. P. WHITE. *Geophys. Lab., Washington. Phys. Rev.* 6, 234-6(1915).—The effects on the thermoelec. power of permanent strain (*i. e.*, hardening) of metals bear no relation to the temporary effects produced by strains which are below the elastic limit. Alloying usually lowers the thermoelec. power of metals. Pt, however, is an exception. Permanent strain usually raises the thermoelectric power, thus acting oppositely to alloying; it lowers the thermoelec. power of some Pt alloys, thus again acting oppositely to alloying. But it raises pure Pt, just as alloying does. No theoretical application is made of these facts. Serious confusion has occurred in the study of thermoelec. power from uncertainty as to the convention used regarding the sign of the effect. That metal should be counted positive which gives current at the cold junction. W. P. WHITE.

Tests of thermoelectric formulas based on bismuth and bismuth-tin alloys. A. E. CASWELL. *Univ. Oregon. Phys. Rev.* 7, 269-77(1916).—By a method already described (*C. A.* 6, 452) the Peltier effect was detd. for Bi and 3 alloys of Bi and Sn. The results, taken together with Schulze's data on elec. and thermal conds. of such alloys, give values for certain electronic const's. which agree better with Drude's than with Thomson's or Lorentz's form of electron theory. W. P. WHITE.

The spontaneous electron emission of glowing metals and the electric glow element. W. SCHLICHTER. *Göttingen. Ann. Physik* 47, 573-640(1915).—Metals heated *in vacuo* usually emit at first positive ions, but with an increasing proportion of negative electrons as time goes on. To measure the discharge an elec. p. d. is usually applied between the emitting and the receiving electrode which prevents any of the electrons from returning whence they started. This p. d., however, may also cause more electrons to be emitted. Hence, to det. the true spontaneous emission it is necessary to omit the applied p. d. S. accomplishes this by having the sending and receiving electrodes sepd. by a distance less than the mean free path of the electrons in the gas present (this requires a high vacuum), by having one electrode inclose the other, and by heating the emitting electrode by radiation through the wall of the vacuum tube, since direct elec. heating usually employed introduces p. d.'s which affect the motions of the electrons. The following experimental results were obtained: (1) Electrons were not given off appreciably until most of the ionic (positive) emission had ceased, as if that inhibited the emission of electrons. (2) As the metal Pt through protracted heating became freer from gas, the emission under applied p. d. shows less excess over the spontaneous emission. Since there is practically no p. d. within a good conductor, the author holds that in a perfectly pure metal the spontaneous and the assisted emission (spontaneous and "saturation" current) would be identical. Absorbed gas probably forms a layer within which is a p. d. due to the applied p. d. and this aids in the escape of electrons. Equality of spontaneous and assisted emission is thus a test of the purity of the metal. In one case, after 24 hours at 1100° the assisted was still more than twice the spontaneous emission. By longer heating at 1200° the ratio was reduced to 1.1. (3) The spontaneous emission itself also became less as the metal became purer. (4) As the emission changes with temp., the spontaneous and assisted

emissions change (for Pt) in the same ratio. There are theoretical reasons for thinking that this indicates that for both the same energy is required to liberate an electron. (5) The admission of air to the tube *at first* diminishes the spontaneous emission, which then increases after heating. The conclusion is that a very superficial layer of gas retards the escape of the electrons, while occluded gas promotes it. (6) In this case the assisted emission was increased, that is, with the help of the applied p. d., even the superficial layer gave off more electrons. (7) Treatment with HNO_3 brought back a very persistent positive emission. Since this was not removed by treatment with H, S. believes that the effect produced is not superficial. He considers that it differs only in degree from the effect of air. (8) After long heating the spontaneous emission finally ceases to fall. This is evidence of a pure electrical emission, characteristic of the pure metal, and not due to chemical action. (9) With Ni there is almost no positive emission. (10) The assisted (saturation) emission is enormously greater than the spontaneous, shows no tendency to become equal to it and varies with temp. according to a different law; this shows that it (the saturation current) is not a pure thermal phenomenon. It is doubtless due to a skin of NiO or similar compd., behaving somewhat like a Wehnelt (CaO) cathode. The saturation current cannot, therefore, be taken as any indication of the emission of Ni itself. (11) When the spontaneously emitting tube is operated as a generator of electric current, its efficiency is almost perfect if loss of heat by radiation, etc., is not taken into account, but is of the order of 10^{-11} .

W. P. WHITE.

Accurate method for the measurement of the conductivity of electrolytes. W. A. TAYLOR AND H. L. CURTIS. *Phys. Rev.* 6, 61-4(1915); cf. *C. A.* 9, 3019.—Continuation of the work before announced. A Vreeland oscillator with a range of frequency between 150 and 3000 cycles and a max. voltage of 54 v. was cut down by means of a transformer to voltages suitable for cond. measurements. The apparent capacity of an electrolytic cell in an arm of an a. c. bridge is very large, about 25 microfarads per sq. cm. for bright Pt electrodes, and several times that value for platinized Pt. The cell to be measured was placed in an arm of the bridge in series with a substitution resistance. With this resistance R set at zero, the resistance and inductance in the bridge are balanced until there is no sound in the telephone. Then the cell is short-circuited and the value of R is adjusted until there is again no sound in the telephone. R is then the resistance of the cell. The oscillator and transformer had to be taken to another room in order to avoid the effects of their fields. Another source of error was the const. temp. bath which, when filled with H_2O , acted as a capacity and changed the apparent resistance of the cell as much as 0.1 ohm. If the solns. and cells were scrupulously clean there was no change in R when the voltage was changed, but if a slight trace of grease was present the value of R varied with the voltage, over the range 0.25 to 4.0 v. There was a slight change of resistance with changing frequency and the difference depended upon the size of the electrodes. The smallest change was found with the largest electrodes, but the change becomes smaller as the resistance of the cell increases. This is doubtless an electrode effect which becomes a smaller factor as the resistance is increased. Change of frequency had very little effect when the electrodes were platinized. Values of R with bright Pt electrodes were obtained with 3 different frequencies and extrapolated to infinite frequency. The difference observed was only 0.02%, all of which may have been due to exptl. error. The work is being continued by S. F. Acree.

R. B. MILLARD.

The conductivity of acids in absolute and aqueous alcohol. II. H. GOLDSCHMIDT. Univ. Christiania. *Z. physik. Chem.* 91, 46-74(1916); cf. *C. A.* 9, 745(1915).—In all the cases investigated, the dissociation of weak acids in alc. is changed in the same manner by additions of H_2O . This change is governed by the equil. const. of the system

H^+ -alc.- H_2O , and by the factor, $1 + 0.9n + 0.3n^2$, which holds for all acids. Here, n represents the normality of the H_2O content of the soln. The conds. at infinite diln. and the dissociation consts. of the following acids have been detd. at 25° : $o\text{-C}_6\text{H}_4(\text{OH})\text{CO}_2\text{H}$ $\lambda_\infty = 86$, $k = 2.2 \times 10^{-8}$; $\text{CHCl}_3\text{CO}_2\text{H}$ 94, 5.2×10^{-8} ; $\text{C}_6\text{H}_5\text{Cl}_2\text{CO}_2\text{H}$ 87, 1.04×10^{-7} ; $\text{C}_6\text{H}_5(\text{NO}_2)_2\text{CO}_2\text{H}$ 86.5, 7.0×10^{-7} ; $\text{CCl}_3\text{CO}_2\text{H}$ 88, 1.5×10^{-8} ; $\text{C}_6\text{H}_5(\text{NO}_2)_2\text{OH}$ 93, 1.75×10^{-4} .

H. JERMAIN CREIGHTON.

The action of the solvent and of the electrolyte on the electromotive force of the alloy copper-zinc. LIVIO CAMBI. Milan. *Rend. r. ist. Lombardo* [2] 48, 826-40 (1915).—A review and bibliography are given of the work that has been done on the electrolytic tension of various binary alloys. C.'s work is divided into a study of the influence of the solvent and the influence of electrolytes. *The influence of the solvent*: The Zn-Cu alloys were prepd. from pure Zn and electrolytic Cu melted in a graphite crucible; those more rich in Zn were fused under a eutectic mixt. of LiCl-KCl (Pushin and Ryazhskii, *C. A.* 7, 1345, 2920); those rich in Cu under a layer of powdered C in an atm. of N. The ingots were turned and filed to a diam. of about 5 mm. and the compn. was detd. by analysis. The ingots were then roasted in a sealed tube for 5 days at 360° for those with 0-50% Cu, at 500° for those with 50-100% Cu. The electrodes were constructed by using receivers similar to those used with Ca and Mg amalgams (*C. A.* 9, 2182, 2834, 3024). The electrodes of the various alloys were opposed to well known normal electrodes. The detns. were made at 25° with a potentiometer graduated to 0.0001 v., with a reflecting galvanometer, and using a standard Cd element. The materials were all carefully purified. The pair $[-\text{Zn}_{100}\text{Cu}_{100} - x | \text{ZnSO}_4 \text{ 0.5 } M | \text{KCl 0.1 } N; \text{HgCl} | \text{Hg} +]$ in H_2O was studied again. The data are given in full for 34 alloys. The e. m. f. dropped from -1.136 v. for pure Zn to -1.064 v. at 31.89% Cu, then sharply to -0.343 v. for 39.60% Cu, then slowly to -0.290 v. for 49.90% Cu, sharply again to -0.195 at 51.80% Cu and then somewhat raggedly to -0.106 at 98.79% Cu. The cell $[-\text{Zn}_{100} - x\text{Cu}_x | \text{ZnCl}_2 \text{ 0.124 } M | \text{KCl 0.02698 } N; \text{HgCl} | \text{Hg} +]$ showed an analogous e. m. f. curve (e. m. f. Cu 0.963 v. in MeOH) up to 45.38% Cu in MeOH soln.; the results for higher Cu alloys are not given. The cell $[-\text{Zn}_{100} - x\text{Cu}_x | \text{ZnCl}_2 \text{ 0.184 } M | \text{AgNO}_3 \text{ 0.1 } M | \text{Ag} +]$ in pyridine soln. gave e. m. f. values beginning at -1.185 v. for pure Cu which show a sharp drop from -1.179 v. at 10.63% Cu to -0.899 v. at 12.65% Cu and was only studied up to 36.90% Cu at which its e. m. f. is -0.630 v. *Influence of electrolytes*: The cyanides were selected for these expts. as representing an extreme case. The results of Spitzer (*Z. Elektrochem.* 11, 345(1905)) show the nature of the variations in the e. m. f. depending on the changes in the concn. of the cyanide solns. C. detd. the e. m. f. for alloys from 0% Cu to 78.63% in the cell $[-\text{Zn}_{100} - x\text{Cu}_x | \text{K}_4\text{Zn}(\text{CN})_6 \text{ 0.25 } M | \text{KOH } N, \text{HgO} | \text{Hg} +]$ (for the Hg electrodes cf. Wilshire, *Z. physik. Chem.* 35, 325(1900)) in which Zn is -1.183 v. Likewise the cell $[-\text{Zn}_{100} - x\text{Cu}_x | \text{KCN 0.25 } M | \text{KOH 0.1 } M, \text{HgO} | \text{Hg} +]$ was studied with 29 alloys from 0% to 100% Cu in which Zn is -1.348 v. and Cu -1.225 v. In both of these curves there is a more or less stepwise drop in the e. m. f. The curve of the e. m. f. of the alloy Zn-Cu toward aq. ZnSO_4 coincides with the data of Pushin (*Z. anorg. Chem.* 36, 232(1903)). P. saw indications of the compds. Zn_2Cu , Zn_3Cu , ZnCu and ZnCu_2 but C. considered that the e. m. f. shows the successive disappearance of the various phases composing the alloy and that the horizontal lines show the various miscibility breaks in the solid state that occur in the system Zn-Cu. Thus both the curves of P. and of C. show approx. the successive decompn. of the solid solns. η , ϵ , γ , β and do not show appreciably the homogeneous fields ϵ and γ . The e. m. f. is certainly too much influenced by secondary phenomena to give a perfect picture corresponding to the constitution of the alloy Zn-Cu. The greater variation in the e. m. f. at about 32% Cu has been attributed by P. and others to the compd.

Zn_3Cu , the existence of which is rendered probable by the ht. of formation of the alloy Zn-Cu, by the sp. vols. and by the detns. of the elec. cond. and thermoelec. force. Parravano has found that the miscibility break $\gamma + \epsilon$ does not extend beyond 30% Cu and in this respect the e. m. f. curve does not give a sufficient sign to distinguish where the bend marks the disappearance of the soln. ϵ , and thus indicates the above compd. in a characteristic way by the e. m. f. of γ . The expts. with electrolytes show a definite parallelism with the above results even in electrolytes as abnormal as the cyanides. The bends at about 14% Cu (limit of the break $\epsilon + \eta$) and at about 32% Cu were observed in all cases studied except in pyridine which did not show the 2nd, owing to passivity phenomena. The various curves show the enormous influence of electrolytes and solvents on the e. m. f. of Zn-Cu. At about 33% Cu there is a drop of 0.15-0.10 v. in cyanide solns., of about 0.70 v. in ZnSO_4 and about 0.56 v. in MeOH. The action of the passivity in these alloys was noted. E. J. WITZEMANN.

The constant c of the Wien-Planck radiation law. E. WARBURG AND C. MÜLLER. Physikalisch-Technische Reichsanstalt. *Ann. Physik* 48, 410-32(1915); cf. *C. A.* 7, 3700.—Using the method of isochromatics, the const. c of the Planck equation was detd. as follows: 14250 micron degrees when the temp. measurement is based on the Stefan-Boltzmann equation, and 14300 or 14400 when the temp. is detd. by the Wien displacement law according as the data of Carvallo or of Paschen are used for the displacement of quartz. PAUL D. FOOTB.

Determination of the Loschmidt number from extinction coefficients of sunlight by use of a photoelectric spectrophotometer. H. DEMBER. Tech. Hochsch., Dresden. *Ber. K. Sach. Ges. Wissenschaften* 67, 106-16(1915).—Using as a basis the formula derived by Planck, $n = 8\pi^2(\mu^2 - 1)^2/3h\lambda^4\mu$ where n = no. mol./ cm^3 at 0° and 760 mm., μ = refractive index, h = extinction coeff., λ = wave length, the value of n was found to be 2.89×10^{19} . Spectrophotoelec. measurements were made upon the solar intensity at wave lengths 0.285 to 0.480 μ from Peak Teneriffa, elevation 3280 m. h was found proportional to $1/\lambda^4$ in the range 0.480 to 0.320 μ but for shorter wave lengths this relation does not hold on account of the presence of absorption bands. The value of n observed is in agreement with detns. by other methods. This is a confirmation of the Rayleigh theory which relates atm. absorption to mol. diffraction. P. D. F.

Experimental evidence for the essential identity of the selective and normal photoelectric effects. R. A. MILLIKAN AND W. H. SOUDER. Univ. Chicago. *Proc. Nat. Acad. Sci.* 2, 19-24(1916).—Wiedmann (*C. A.* 9, 3166) has confirmed previous work by R. and S., showing that the photoelec. action by short wave lengths is relatively larger when the metal surface is fresh, but when some active gas is present a short exposure to it brings the emission of electrons by longer wave lengths (near the selective maximum) to preponderance. That there is no sharp demarcation between the normal and selective effects is shown by the facts: that the energy of emission is in all cases given by $mv^2/2 = h\nu - p$ (see following abstr.); that the amt. of emission is not dependent on the angle of incidence or the azimuth of polarization, but solely on the coincidence of the impressed frequency with a natural frequency; and that as a gas acts progressively on a fresh surface the normal effect merges gradually into the selective. No distinction could be drawn between the two in the case of Li. G. L. WENDT.

Quantum relations in photoelectric phenomena. R. A. MILLIKAN. Univ. Chicago. *Proc. Nat. Acad. Sci.* 2, 78-83(1916).—Curves are given which prove several deductions from Einstein's photoelec. quantum theory equation: $mv^2/2 = h\nu - p$, where h is Planck's constant, ν the frequency of the incident light, and p the work necessary to sep. an electron from the surface of the metal. There is a definite max. of electronic emission under the stimulus of a frequency, ν . There is a linear relation between ν

and V_0 , the opposing potential needed to stop emission. The slope of the $V_0\nu$ line, multiplied by e , the electronic charge, gives h , here found to be 6.57×10^{-27} . The intercept of the $V_0\nu$ line with the ν -axis is the frequency at which the illuminated substance first becomes photo-sensitive. The contact e. m. f. = $[(h\nu_0 - h\nu_0')/e] - (V_0 - V_0')$, where ν_0 ' and V_0 ' refer to the surrounding Faraday cylinder used in the measurements. These relations, with Schottky's proof (*C. A.* 8, 3746) that the contact e. m. f. is independent of the temp., evince the correctness of the quantum assumptions. G. L. WENDT.

Complete photoelectric emission. O. W. RICHARDSON. Univ. London. *Phil. Mag.* 31, 149-55(1916).—This term is used to signify the emission of electrons by a body under the photoelectric action of its own complete black-body radiation at high temps. The current density for this effect with Pt at 2000° K. is calcd. to be 2.1×10^{-11} amp./cm². This is at least 5000 times less than the observed thermionic current at that temp., so that this effect is relatively unimportant in the explanation of thermionic currents. G. L. WENDT.

✓ **A mathematical relation between the temperatures of liquefaction and the absorption coefficients of gases.** A. IMHOF. Zürich. *Z. physik. Chem.* 91, 124-8 (1916).—If the temp. -100° is taken as zero, it is found that for the majority of gases which obey Henry's law the temp. of liquefaction (b. p.) is approx. proportional to the logarithm of the absorption coeff. at 0° and 760 mm. pressure. The expression $T_0 = 27.4 \log a$ or $a = e^{T/27.4}$, where a represents the coeff. of absorption, has been found to hold for Ne, N, CO, A, O, CH₄, Kr, NO, O₃, N₂O, C₂H₂, CO₂ and H₂S, but not for He nor H. H. JERMAIN CREIGHTON.

Effect of temperature on the coefficient of absorption of certain glasses of known composition. K. S. GIBSON. *Phys. Rev.* 7, 194-202(1916).—Zn glass, non-Pb, and borosilicate, colored with Cd and Se, a Zn glass colored with CdS and a Pb glass colored with U were tested for change of absorption with temp. between -180 and 430° in a special app. The specimens ranged from red through orange, amber, lemon-yellow to canary. An enormous increase in the coeff. of absorption in certain parts of the spectrum was brought about by heating from -180 to 430° . A transparent glass for 0.66μ at the lowest temp. became nearly opaque when heated. In spite of these large changes there was a nearly complete recovery after heating, and room temp. curves taken a year after the heating were identical with those taken before. There was also a change of color in the specimens with increasing temp., the orange glass became yellow at -180 and brilliantly red at 430° . The absorption bands of U glass near the region of general absorption disappeared on heating and the specimen showed a green fluorescence, probably due to the band 0.49μ . E. B. MILLARD.

The distribution of energy in the normal radiation spectrum. LEIGH PAGE. Sloane Phys. Lab. *Phys. Rev.* 7, 229-40(1916).—Theoretical. Planck's radiation formula is derived from the expressions given by classical dynamics and electrodynamics for the absorption and radiation of energy with the aid of the supplemental assumption that the motion of an absorbing and emitting linear oscillator of frequency ν is stable only when the energy of its oscillations is an integral multiple of $h\nu$. This assumption avoids the necessity of replacing the emission of energy demanded by the electrodynamic equations by an emission that is discontinuous in time. The partition of energy among the different degrees of freedom in the ether is investigated and found to be the same as in material oscillators. PAUL D. FOOTE.

A comparison of the arc and spark spectra of nickel produced under pressure. E. G. BILHAM. Kew Observatory. *Phil. Mag.* 31, 163-70(1916); cf. *C. A.* 9, 882. —A criticism of Duffield's conclusions (*C. A.* 9, 3022) on the basis that the displace-

ments he observes are incorrect and too high. B. concludes that the behavior of lines which are easily reversed or tend to reverse is approx. the same whether developed in the arc or in the spark under pressure. Abnormalities are exhibited by reversed lines.

G. I. WENDT.

The X-ray spectrum of tungsten. W. S. GORTON. Johns Hopkins Hospital. *Phys. Rev.* 7, 203-8(1916).—Using a Coolidge tube excited by a 10 kw. interrupterless Snook Roentgen Co. generator, and calcite and rock salt analyzers, the X-ray spectrum of tungsten was observed photographically. The following lines were detd.: ($\lambda, 10^4 \text{ cm.}$) 1.476, 1.466, 1.292, 1.283, 1.275, 1.256, 1.237, 1.094, 1.057, 1.025. The value used for the spacing of the atomic planes of the 100 face of rock salt was that detd. by Bragg, $2.814 \times 10^{-8} \text{ cm.}$ The spacing for the rhombohedral (100) face of calcite as calcd. from the present work is $3.028 \times 10^{-8} \text{ cm.}$

PAUL D. FOOTE.

Magnetic properties of electrolytic iron deposited in magnetic fields. TAKÉ SONÉ. *Sci. Reports Tohoku Imp. Univ.* [1] 4, 313-21(1916).—The Fe was deposited in fields up to 2600 gauss. A magnetic field affects only the orientation of the mols. of the electrolytically deposited Fe, but not their relative configuration, and hence the initial magnetism, but not the form of the hysteresis loop is affected. The curve of initial magnetism of the Fe deposited in a magnetic field lies higher than the curve for specimens in zero field, and the hysteresis loop is considerably wider, though of the same general form.

E. B. MILLARD.

Theoretical considerations on hydrogenation on the basis of velocity measurements made on the hydrogenation of fumaric acid with palladium sol as catalyzer. A. KOREVAAR. Rijswijk. *Chem. Weekblad* 13, 98-107(1916).—A preliminary paper, containing no exptl. results. The rate of hydrogenation of fumaric acid in the presence of Pd sol is in accordance with Nernst's surface film theory of heterogeneous reactions. The velocity was found to increase as the $2/3$ power of the rate of stirring, and the temp. coeff. per 10° was 1.25, instead of 1.7, the theoretical for microheterogeneous systems. With small concn. of Pd sol, doubling the amt. of sol more than doubled the rate of hydrogenation; this has been explained by Bredig as a common property of microheterogeneous systems due to increased Brownian movement. Since in systems of this type the apparent rate of the reaction is detd. by the diffusion of the reacting mols. through the stationary film, at high initial concn. of fumaric acid the rate should be detd. by the rate of diffusion of the H, and hence should be const.; when the concn. of fumaric acid decreases below a value detd. by the H concn. and the ratio between the diffusion consts. of the 2 mol. species the rate should be detd. by the diffusion of fumaric acid, and hence should be that of a 1st order reaction. This is in harmony with the expts.

GEORGE W. MOREY.

Boiling and condensing points of alcohol-water mixtures. P. N. EVANS. *J. Ind. Eng. Chem.* 8, 260-2(1916).—An exptl. study to ascertain the relation between the b. p. (or condensing point) and the compn. of both the liquid and vapor phases. The procedure is given in detail. Results obtained with 43 mixts., ranging from 91 to 0% alc., are reported in a table. The relations existing between the b. p., or condensing point, and the compn. of the liquid and vapor phases are plotted and a convenient table of results (estd. from the curves) is given, which enables one to det. quickly the approx. concn. of any alc.-H₂O mixt. by noting its b. p., with corrections for barometric pressure and exposed Hg column. It is also possible to tell the approx. compn. of both liquid and vapor (or distillate) at any moment during the distn. of a mixt. The accuracy is less than by the usual and more difficult method of distn. and the detn. of the d. of the distillate with a pycnometer. Cf. Pohl, *Jahresber.* 1850, 455; Dupré and [Page], *Trans. Roy. Soc. London* 1869, 591; Wiley, *J. Am. Chem. Soc.* 18, 1063(1896); Noyes, *Ibid* 23, 463(1901); Haywood, *J. Phys. Chem.* 3, 318(1899).

F. W. SMITHER.

Rhythmic crystallization. R. E. LIESEGANG. *Naturwissensch.* 3, 500-2 (1915).

—Three kinds of crystals may be formed when a surface of a gelatin soln. containing salt is allowed to dry until it begins to crystallize at the edges. Those termed rhythmic crystals form in parallel cryst. bands around the edge and sepd. from each other by crystal-free or partially crystd. bands. Küster (*C. A.* 8, 2971) described a new crystn. of this form in which the crystal ring is formed somewhat laterally to the outside edge. L. offers an explanation for this formation. W. E. RUDER.

The formation of ozone in the upper atmosphere, and its influence on the optical properties of the sky. J. N. PRING. *Sci. Prog. Twentieth Cent.* 9, 448-70 (1915).—This article discusses some factors which det. the optical properties of the atm., chem. detn. of constituents of the atm., the action of ultraviolet light on air, the detn. of O_3 in the atm. at high altitudes, and the influence of O_3 on the nature of light from the sky. It is stated that "the optical properties of the atm. must lie in the precise detn. of the presence of such compds. as O_3 , H_2O_2 , and N peroxide," and methods for such detns. are described. Although the methods used were designed to detect very minute amts. of the substances named, they failed to show the presence of appreciable amts. of oxides of N or H_2O_2 resulting from the action of ultraviolet light on air, and they also failed to show the presence of detectable amts. of these substances in the air from high altitudes. While the tests do not preclude the possibility of the formation of these substances they show that the quantity formed is negligibly small when compared with O_3 . E. H.

3. RADIOACTIVITY.

WILLIAM H. ROSS.

X-Ray wave-lengths. WM. DUANE AND FRANKLIN L. HUNT. Harvard Univ. *Phys. Rev.* [2] 6, 166-71 (1916).—The X-rays emitted under a const. difference in potential are not homogeneous, and both the coeff. of absorption and the effective wave-length decrease as the rays pass through matter. For any given potential there is a definite min. wave-length emitted in accordance with the equation: $Ve = h\nu$, where V is the voltage employed, e the charge on the electron, h Planck's radiation const. and ν the max. frequency emitted. The mean value for h was found to be 6.39×10^{-27} .

G. L. WENDT.

Emission quanta of characteristic X-rays. DAVID L. WEBSTER. Harvard Univ. *Proc. Nat. Acad. Sci.* 2, 90-4 (1916).—Duane and Hunt's quantum relation (cf. preceding abstr.) is verified for the general radiation, with 6.52×10^{-27} resulting as the value for Planck's const. But no characteristic lines are excited at a potential which is sufficient to give general radiation of the same wave-length unless the potential exceeds a critical value which would give a general radiation of wave-length 1.3% shorter than that of the characteristic γ -line. Since at just this wave-length absorption of the general radiation is very marked and is accompanied by a strong characteristic fluorescence, W. suggests that the characteristic rays, like fluorescence, result from the excitation of higher frequency oscillators and their subsequent drop on emission. The intensities of all lines in the characteristic spectrum increase in the same ratio with increase of potential above the critical value.

G. L. WENDT.

The influence of foreign substances upon the adsorption of uranium X_1 by charcoal. H. FREUNDLICH AND H. KAEMPFER. Braunschweig. *Z. physik. Chem.* 90, 581-716 (1915).—The expts. of Ritzel (*C. A.* 4, 1843) on the removal of $U X_1$ from animal charcoal by Th have been confirmed. The action occurs in the presence of small quantities; a content of about 0.0004 millimol. of $Th(NO_3)_4$ (equiv. to about 0.2 mg. per l.) increases the quantity of $U X_1$ remaining in the soln. after shaking with charcoal by about 20%. This action is not sp. for Th or the radioelements, but occurs with a large number of substances: Zr salts, BzOH, strychnine nitrate, basic dyes, etc. Investigation has shown that a difference exists between the adsorption of $Th(NO_3)_4$ and the other foreign substances. The adsorption of BzOH, strychnine nitrate and $ZrOCl_2$ by animal charcoal can be measured by the help of radioactivity as follows: the end concn. of these substances in the soln. is detd. on the basis of the displacing action which they exert upon the $U X_1$, when they are adsorbed together with this substance by the charcoal. In this way the usual adsorption isotherm has been found for BzOH and $ZrOCl_2$ in the

concn. region investigated; strychnine nitrate tends towards a satn. In all 3 cases an end point is reached which is independent of the time. The adsorption of $\text{Th}(\text{NO}_3)_4$ by animal charcoal differs from that of the above-mentioned substances, inasmuch as the end concn. appears to decrease considerably as the time increases. This increase is not confirmed, however, when the end concn. of $\text{Th}(\text{NO}_3)_4$ is measured with the nephelometer on the basis of the small solubility of $\text{Th}(\text{C}_2\text{O}_4)_2$. This contradiction is explained on the assumption that, after shaking with animal charcoal, a $\text{Th}(\text{NO}_3)_4$ soln. is able to remove the U X_1 to a much less extent. It has also been found that U X_1 is more strongly adsorbed from a soln. of $\text{UO}_2(\text{NO}_3)_2$ that has been shaken with charcoal and in which the U X_1 has formed anew, than from a soln. that has not been so treated. The preceding observations are best explained on the assumption that in the Th or the $\text{UO}_2(\text{NO}_3)_2$ soln. unknown substances, such as radioelements, are present, which in even small quantities bring about the removal of U X_1 from charcoal. $\text{Th}(\text{NO}_3)_4$ differs from the other active substances in that it does not merely bring about the removal of U X_1 in consequence of simultaneous adsorption, but also when it is subsequently added to a charcoal that has adsorbed U X_1 . The other substances do not remove U X_1 on subsequent addition. This difference in behavior may be explained by assuming that both $\text{Th}(\text{NO}_3)_4$ and the foreign substances contained in this substance are concd. not only on the surface of the charcoal but also in the interior. In consequence of this, subsequent additions of $\text{Th}(\text{NO}_3)_4$ can remove the U X_1 compressed in the interior of the charcoal, while those substances which are only concd. on the surface of the charcoal (such as BzOH) cannot do so. The results of the investigation lead to the conclusion that Soddy's view, that the removal of U X_1 from charcoal by Th depends on the isotopy of both substances, is not sustained. On the other hand, the fact that other substances remove U X_1 from charcoal does not contradict the isotopy of Th and U X_1 or the far-reaching chem. similarity of isotopic elements. The adsorption of $\text{Th}(\text{NO}_3)_4$ by animal charcoal has been measured by the detn. of the end concn. by means of the nephelometer. The exponent in the adsorption isotherm was, as in the case of the adsorption of U X_1 by charcoal, approx. equal to unity. The removal of U X_1 from charcoal by the other active substances depends chiefly upon their adsorbability. Not only is the removal due to the adsorption of the foreign substances, but also to the fact that they actually hinder the adsorption of the U X_1 .

H. JERMAIN CREIGHTON.

The question of isotopic elements. II. Rejoinder to the reply of G. v. Hevesy and F. Paneth. K. FAJANS. Karlsruhe. *Physik. Z.* 17, 1-4(1916); cf. *C. A.* 9, 1149.—F. admits the validity of the claims of v. Hevesy and Paneth (*C. A.* 9, 175, 1271, 2485) respecting the replaceability of isotopic elements in their electrochem. reactions, and of their deductions from these reactions. He raises further questions as to the degree of identity involved in replaceability in various kinds of reactions. Questions of terminology and of priority are also brought up.

S. C. LIND.

The question of isotopic elements. III. Reply to the foregoing paper of K. Fajans. G. v. HEVESY AND F. PANETH. Vienna. *Physik. Z.* 17, 4-6(1916).—Brief summary of points previously discussed and rejoinder to Fajans (cf. preceding abstract).

S. C. LIND.

The branching point of the thorium series. S. LORIA. Vienna. *Physik. Z.* 17, 6-9(1916).—Barratt and Wood (*C. A.* 8, 3530) have measured the % of Th C vaporized at temps. from 770 to 1200°. A pronounced change in curvature at the point represented by a temp. of 920° and 35% vaporization led them to believe that Th C is a β -radiator decomposing to the extent of 35% into the α -radiator, Th C_α , and into a second α -radiator, Th C_β , according to the scheme:

L. points out that the application of the Soddy-Russell-Fajans transformation rule to this scheme leads to the false conclusion that Th D belongs to the IV group and is isotopic with Pb instead of with Tl. L. has made a new and more accurate detn. of the vaporization curve of Th C and has supplemented it with a similar detn. for Ra C. He agrees with Barratt and Wood in finding a change of direction in the curve for Th C but further finds that the curve for Ra C is practically identical with that of Th C as would be expected for isotopic elements. Since, however, the ratio of the 2 branches in the Ra series is about 3 in 10,000 it seems impossible that it could be detected in a vaporization curve as was assumed for Th C by Barratt and Wood. But it is clear that the relations are parallel in the 2 series, and L., therefore, concludes that the assumption of Barratt and Wood was wrong and that the previously accepted scheme of branching

is correct. L. believes that the change in the

curve is to be explained on chem. grounds, probably by oxidation, rather than on radioactive grounds.

S. C. LIND.

Stereoscopic photography by Röntgen rays. II. B. ALEXANDER. *Physik. Z.* 17, 15-6(1916); cf. *C. A.* 9, 2485.—A. admits that the stereoscopic effects to be obtained in ordinary photography (Knipping, *C. A.* 10, 424) may have played a certain role in the photographs he obtained with X-rays, but holds that indirect radiation from the walls of the X-ray tube and other sources assists in bringing out the stereoscopic effect. A new photograph is presented which was made with the anticathode wholly screened by a thick lead plate; it is claimed to consist of 4 different images. S. C. LIND.

The penetrating radiation of the atmosphere. A. GÖCKEL. Freiburg, Switzerland. *Physik. Z.* 16, 345-52(1915).—Two kinds of penetrating radiations are found in the atm., one of undoubted radioactive origin coming from the earth's crust, and another which increases rapidly in intensity on going to higher altitudes and which may be of cosmic origin. A depth of water of 3.5 m. is not sufficient to absorb entirely the latter penetrating rays. Observations above glaciers show the same increase with altitude as that shown by balloon observations. The radiation is more intense above crystalline structure than over cultivated land of alluvial nature. Diurnal variations in the second kind of radiation could not be detd. at Freiburg (Switzerland). The fraction of the first radiation coming from the earth is greater in warm weather. Even at 2200 m., variations in the part of the radiation coming from the earth still occur from day to day. No satisfactory explanation of the origin of the cosmic(?) radiation can be offered as yet. The equality of the intensity day and night seems to preclude consideration of the sun as the possible source.

S. C. LIND.

Photographic measurement of the hardness of Röntgen rays. J. K. A. WERTHEIM-SALOMONSON. Amsterdam. *Physik. Z.* 16, 389-90(1915).—Reply to Voltz (*C. A.* 9, 424) who claimed the photographic method of measuring the hardness of X-rays to be inaccurate and that the method of measuring the implied voltage is preferable. According to W.-S. the use of the electrostatic voltmeter as employed by Voltz is allowable only when permanent static charging of the series condenser is carefully avoided and when a source of unvarying direct current is used to excite the X-ray tube. Under

less favorable conditions the electrical method is not suitable. Voltz's claim of the irregularities of the photographic method owing to differences in plates and developer have not been found by the author who still regards the photographic method as the most satisfactory under present conditions.

S. C. LIND.

The favorable form of discharge for Röntgen apparatus. B. WINAVER. Frankfurt a/M. *Physik. Z.* 16, 391-5(1915).—A deduction of the characteristics of the form of discharge for continued operation of X-ray tubes results in the establishment of 2 general requirements: (1) that the source of current is most favorable in which a definite allowable load is carried in a small number of current impulses of the shortest possible duration, that is, by a current with the "narrowest" possible curve dimensions; and (2) that of 2 sources of current, the one which at the same load produces the more heating of the anticathode is to be regarded as the more favorable. These 2 requirements were tested by expt. and found to be valid.

S. C. LIND.

The theory of the beta rays. H. TH. WOLFF. Dresden. *Physik. Z.* 16, 417-9 (1915).—A mathematical consideration of β -rays which have their origin in the nucleus of the atom, making use of the Rutherford conception of the atom and assuming further that no energy is radiated from the electron before its projection from the at. nucleus around the center of which it is revolving with great velocity. The general laws of mechanics, the theory of electricity, and the relativity principle are assumed. It is found that the work done upon the electron by the repulsive force of the negative charges of the nucleus is quite sufficient to account for the velocity of the most rapid β -rays.

S. C. LIND.

The periodic system of the elements, the radioactive transformations, and the structure of the atom. K. FAJANS. Karlsruhe. *Physik. Z.* 16, 456-86(1915); cf. C. A. 10, 421.—A very complete summary, with full references, which presents the historical development of the subject of atomistics from the radioactive and isotopic standpoints.

S. C. LIND.

4. ELECTROCHEMISTRY.

COLIN G. FINK.

Walther Löb. ANON. *Chem. Ztg.* 40, 145(1916).—Died Feb. 3, 1916. An obituary.

J. H. MOORE.

Water power and waste energy. MAX DU BOIS. *Lumière elec.* 32, 193-6(1916).—When the price (in France) is less than 1 centime per kw. hr. the energy now wasted at night, etc., can be utilized to advantage in certain electrochem. industries which are adaptable to intermittent service. Most of the Swiss water power plants furnish elec. energy 24 hrs. a day at less than 1 centime per kw.-hr. Statistics of the electrochem. industries of the world are tabulated; e. g., the annual world's production of H amounts to 63,000 tons (1913). The cost of current per kg. of fixed N is 75 centimes by the Birkeland and Eyde process, 37.5 by the Pauling, and 19 by the Moscicki.

C. G. F.

Operating data on an important electric furnace installation. W. J. KYLS. *Elec. Rev. West. Elec.* 68, 374-6(1916).—The Snyder single-phase, Rennerfelt 2-phase, and Heroult 3-phase furnaces are briefly described. The Treadwell Eng. Co. has a Heroult furnace of 2 tons capacity, operating 3-4 heats per 24-hr. day. Magnetic steel, auto parts, gear-cases, and cement-mill and special steel castings are made. The elec. furnace shows a 200-kw. demand per ton furnace capacity and with a cold charge, melting and refining, 800-850 kw. hrs. per ton of steel. Addition of hot or molten metal lowers the requirements to 350-400 kw. hrs. per ton steel and increases the output about 60%

An a. c., 3-phase, 60-cycle, is delivered at 11,000 v. and transformed to 80-85 v., 2500 amp. The raw material consists of equal quantities of heads and gates of previous heats, and purchased steel scrap. The furnace is lined with magnesite brick. The slag formed in the first period is removed by tilting the furnace; charcoal is added for re-carbonizing, together with lime, fluorspar and ferro-silicon. Castings may be poured directly from the ladle or by means of small ladles and shanks. Chem. analyses, fiber stress and tests of unannealed steel, of the same, annealed, and of 0.40% C annealed steel are given.

W. H. BOYNTON.

The behavior of magnesia in the carbide-furnace. I. N. KAMEYAMA. *J. Chem. Ind. Japan* 19, 41(1916).—The assumption that the MgO in the lime in the CaC_2 furnace is reduced to Mg and transformed to nitride so that the C_2H_2 evolved from such carbide contains NH_3 is erroneous. The reduced Mg is reconverted into MgO in the furnace atm. (mainly CO). This conclusion is based on the following: (1) The N content of carbides made with CaO and with CaO mixed with MgCO_3 was 0.12-0.42%; one sample very low in carbide contained 0.9%. (2) To detect and det. nitride in the presence of CaC_2 and CaCN_2 , the carbide is mixed with H_2O and distd. under reduced pressure over CaO. By this method NH_3 is formed only from nitrides and not from CaCN_2 . The carbide used yielded 0.04-0.09% of nitride N. No relation was found between nitride, MgO, and total N. The non-nitride N exists mainly as CaCN_2 . (3) The behavior of Mg vapor in the atm. of the carbide furnace was investigated. The dissociation pressure of Mg_3N_2 , reaching equil. from both sides, was found to be 4.0 cm. Hg at 730°. Other expts., in which equil. was not reached from both sides, at 720-800°, did not agree among themselves or with the above value. The cause of this deviation is perhaps the formation of a solid soln. of Mg_3N_2 and Mg, since one detn. in which 0.3 of the Mg was in the form of Mg_3N_2 showed a much higher dissociation pressure. Further work is in progress.

F. W. SMITH.

Fixation of atmospheric nitrogen. W. S. LANDIS. *Trans. Am. Electrochem. Soc.* 29 (advance copy); *Met. Chem. Eng.* 14, 260(1916); cf. *C. A.* 9, 1719.—Germany now has plants with an annual production of almost 500,000 tons of cyanamide and nearly 10,000 tons of arc-process HNO_3 , practically all of which have been built and set into operation within 18 mos. An investment of \$100,000,000 is represented in this work. On this continent most of the cyanamide is made in Canada under American direction and is carried on at a higher efficiency than in German plants and a higher grade product is produced. We have in this country an intimate knowledge of design and experience in operation of the successful NH_3 oxidation process and are to-day in as good, if not a better, position than Germany was to supply our own HNO_3 for munition purposes.

W. E. RUDER.

A new electrolytic oxygen and hydrogen installation in a shipbuilding plant. ANON. *Met. Chem. Eng.* 14, 288-9(1916); cf. *Elec. Rev. West. Elec.* 66, 1170(1915).—The National electrolyzer, which is of the improved filter-press type, consists mainly of a number of decompn. chambers connected in series. The chambers are formed by clamping together a series of insulated cast-iron electrodes so recessed and grooved that each plate forms a chamber with its neighbor. The electrodes are insulated from one another by means of patented rubber-bound asbestos diaphragms. The electrodes have corrugated surfaces and are composed of a special alloy heavily coated with Ni. The electrolyte is a 21% soln. of pure KOH in distd. H_2O . Under normal conditions, the voltage required is less than 2 v. per cell. Thus, an electrolyzer containing 55 cells can be operated on a 110-v. circuit. The electrolyzers will stand an overload of 50% without any ill effects. The gases produced are of very high purity; the O is 99.5%. (Cf. *C. A.* 10, 561.)

H. JERMAIN CREIGHTON.

Electrolytic zinc. W. R. INGALLS. *Trans. Am. Electrochem. Soc.* 29 (advance copy); *Eng. Mining J.* 101, 425-8(1916); *Met. Chem. Eng.* 14, 264-5(1916).—A description is given of the process used by the Anaconda Co. at Great Falls, Mont. The Zn ore is concd., preferably by flotation, and the concentrate is roasted at a temp. not exceeding 1350° F. so as to produce a calcine containing 2-3% of S. The calcine is treated with dil. H_2SO_4 (spent electrolyte plus fresh acid), MnO_2 is added to oxidize Fe, and the latter pptd. with $CaCO_3$. Sb and As are carried down with the $Fe(OH)_3$. Cu and Cd are removed by treatment with metallic Zn. The Zn is deposited on Al plates with a c. d. of 20-30 amp. per sq. ft. of cathode surface. The anodes are pure Pb. The voltage drop is 3.8-3.4 in 21 cells. The Zn deposit is stripped off every 48 hrs. and sent to the melting furnace. A brief history of previous work on the electrolytic recovery of Zn and descriptions of other plants are given. The essentials for the commercial success of electrolytic Zn are: (1) exceptionally cheap hydroelec. power, or (2) utilization of by-products such as Cl, or (3) exceptionally favorable conditions, such as high grade ore or high Ag content. High purity Zn (over 99.9%) is easily obtained with the electrolytic process. I. believes that the process will not revolutionize the metallurgy of Zn, and that when the war is over, the conditions in the Zn industry will return to normal. Great improvements have lately been made in the flotation treatment of the ore and in the roasting. E. W. BOUGHTON.

Metallurgical operations at the Chile Exploration Co. (Duriron anodes for copper cells.) C. A. ROSE. *Eng. Mining J.* 101, 321-6(1916).—A description with illustrations and flow sheet of the 10,000 ton leaching plant of the Chile Exploration Co., Chuquicamata, Chile. The process used, acid lixiviation and electrodeposition, was in detail especially devised for the type of ore (mainly brochantite). The plant comprises crushing, leaching, dechloridizing, pumping, pptg. and smelting and melting units. Large reinforced concrete leaching tanks, lined with a 1 to 1 1/4 in. layer of asphalt mastic, are used, and are discharged by 6-ton clamshell buckets. The dechloridizing plant contains 22 tube mills 4 ft. diam. by 30 ft. long. Magnetite anodes made in Germany had to be dispensed with on account of the war, and anodes of duriron were substituted. From 15 to 20 times its wt. of Cu can be deposited on a duriron anode in $CuSO_4$ soln. before it is entirely corroded away. Duriron anodes have an advantage over magnetite in their mechanical strength, but they have a much higher overvoltage, which is a decided disadvantage. About 15% more elec. energy is required with duriron than with magnetite anodes for the deposition of the same amt. of Cu; this necessitates cooling the electrolyte in a wide cascade launder after partial electrolysis, and then running soln. back into the tank house to complete the electrolysis. The purity of the Cu produced is somewhat higher than that from American electrolytic refineries; its cond. is from 100.5 to 101% Matthiessen's standard. Cf. C. A. 8, 2545. F. W. SMITHER.

Speeding up the electrodeposit. C. H. PROCTOR. *Metal. Ind.* 14, 73(1916).—The time required for electroplating may be decreased by increasing the metal concn. of the electrolyte. The advantages of the use of single Ni salts in Ni plating are discussed. H. JERMAIN CREIGHTON.

Cyanide versus acid plating solutions. C. DITTMAR. *Metal Ind.* 14, 78(1916).—A number of considerations in favor of the abandonment of the duplex Cu-plating process are discussed. H. JERMAIN CREIGHTON.

Development of the incandescent electric lamp. ERNEST COUSTET. *Rev. gen. sci.* 27, 88-93(1916). E. H.

Results obtained with nitrogen-filled lamps. R. PALMER. *Elec. J.* 13, 225 (1915); cf. C. A. 10, 18.—Many factors entering into the actual operation of flame

arc lamps, such as deposit on the globe, etching of the globes by the gases, etc., reduce considerably its advantage over the gas-filled incandescent lamps of supplying 17.5 lumens per watt as against 11 lumens per watt. Tests show that the av. efficiency during the life of the arc lamp inner globe is 55%, thus decreasing the actual efficiency to 9.6 lumens per watt. It has been demonstrated that the av. efficient illumination with the 325 watt 600 c. p. N-filled incandescent W lamp is practically equivalent to the a. c. flaming arc requiring 465 watts. Moreover, units of from 60 to 1000 c. p. may be used on the same circuit. A comparative table giving Chicago conditions shows a total annual cost per lamp of \$50.31 for the 465 w. flaming arc and \$40.66 for the 325 w. N-filled W lamp.

W. E. RUDER.

Electrical precipitation, Stokes law and the removal of particles from liquids. W. W. STRONG. Carnegie Inst., Pittsburg. *Ann. Physik* 48, 251-60(1915); cf. *C. A.* 7, 2107; 9, 1273.—Stokes law is applied to calc. the theoretical quantity of energy required for the removal of dust, smoke and vapor from gases. The process of the elec. sepn. comprizes a stage of elec. static polarization, a "nuclear coherer" stage, a charging stage and the Stokes stage. In order to make the charge of the smoke particles as general and as large as possible, the corona discharge must be made as intensive as possible, without having it become an arc discharge. In the Stokes stage currents very large ions occur, which charge the outer cylinder on passing it. It has been found in the case of fine smoke that about 4% of the elec. energy of the corona discharge is used in overcoming friction. In conclusion, it is pointed out that relations between the spark potential and the strength of the corona discharge must be detd.

H. JERMAIN CREIGHTON.

Bakelite-dilecto. A new insulating material. ANON. *Elec. Rev. West. Elec.* 68, 479(1916).—This is of exceptionally high dielec. strength, is waterproof, unaffected by O_2 , highly resistant to heat and acids, and exceptionally tough. It is easily molded, machined and tapped. It is built up of successive layers of fibrous material satd. with bakelite and compressed together at high pressure.

C. G. F.

Non-corrosive "binding post." H. T. LEAVENWORTH. *Metal Ind.* 14, 17(1916); see fig.—L. describes a corrosion-proof Hg cup connection, for Pt electrodes, to be used in place of the brass binding post which is readily attacked by acid spray resulting in poor elec. contact. The supporting arm (lignum vitae, bakelite, or hard rubber) is $\frac{1}{8} \times \frac{1}{8} \times 6$ in.; one end of this arm is fastened to an upright support. At the other end, on either side, is a clamp which serves merely as a rigid support for the electrode. Next to each clamp is a $\frac{1}{16}$ in. hole in the bakelite into which a short glass tube is fitted. Through the lower, closed end of each tube is fused a Pt wire. The outer Pt ends are soldered, resp., to the 2 Cu leads of the current supply. The inner ends contact with the Hg which is filled into the tubes or cups. The ends of the stems of the 2 electrodes are bent back into the shape of a hook and dipped, one into each of the cups. The elec. contact thus formed is not affected by the acid spray rising from the soln. during the course of a detn.

Storage battery. W. A. CROWDUS. U. S., 1,173,651, Feb. 29. Structural features.

Storage battery. J. W. EAST. U. S., 1,172,586, Feb. 22. Structural features.

Storage battery. J. N. DAVIS. U. S., 1,171,597, Feb. 15. The separator plates of the battery are formed of perforated hard rubber with an inner layer of asbestos.

Galvanic battery. W. HICKMANN. U. S., 1,173,965, Feb. 29. Acid manganite of Zn or other metal is used as depolarizer in cells of the Leclanché type.

Electrolytic cells for producing hydrogen and oxygen. G. HALTER. U. S., 1,172,-885-6-7, Feb. 22.

Cell for electrolysis of water. W. C. BUCKNAM. U. S., 1,172,932, Feb. 22.

Electrolytic meters. H. S. HATFIELD. U. S., 1,173,570, Feb. 29. A cathode of Au plated with Rh is used with a Pt anode in electrolytic measuring instruments of the Hookham and Holden type. The use of Rh gives a current in the cell which is practically proportional to the main current at all loads.

Device for supporting electrodes of electric furnaces. I. HECHENBLEIKNER. U. S., 1,173,960, Feb. 29.

Arc light electrodes. C. R. KRUEGER. U. S., 1,173,005, Feb. 22. Magnetite 57.25, rutile 28.75, Ti carbide 10, chromite 4 and LiF 1 part are added to arc lamp electrodes to obtain high luminosity without "puddling." Cf. C. A. 9, 3176.

Arc lamp electrodes. W. R. MOTT. U. S., 1,173,370, Feb. 29. ThF_4 is added to arc lamp electrodes with at least 1.5 times its wt. of other rare earth fluoride to increase the efficiency of the light for photography. Cf. C. A. 9, 2488.

Electrodeposition of metals from ore solutions. R. R. GOODRICH. U. S., 1,171,-782, Feb. 15. Solns. of metals, *e. g.*, from extg. Cu ores, are electrolyzed while the soln. is maintained in circulation throughout the entire series of electrolytic cells employed and simultaneously an independent circulation of electrolyte is maintained in part of the series of cells to insure substantial uniformity of concn. of the soln. in each such subdivision of the series, *e. g.*, where electrolysis of Cu solns. is carried out in stages in each of which 1-1.5% of Cu may be taken out of a soln. carrying 6%.

Electrolysis of sulfur ores. H. S. MACKAY. Can., 156,097, Sept. 28, 1915. From the elements of the ore is produced a solvent for the metal, the soln. is electrolyzed and during the process the ore is continuously treated so as to produce and maintain a high efficiency of the solvent and electrolyte.

Electrolysis. B. B. CROMBIE and C. J. A. KALZIEL. Brit., 21,513, Oct. 26, 1914. Electrodes for use in purifying liquids consist of plates of Al-Pt alloy, the proportions of the two metals being, *e. g.*, 1 lb. to 3 g., resp.

Electrolysis. G. PLANCO. Brit., 21,727, Oct. 29, 1914. A thick insulating border is cast on to a diaphragm so as to serve as a distance piece between electrode plates. Preferably, the same material is used for both diaphragm and border. A frame of portland cement, preferably reinforced, may be used with a diaphragm of asbestos fabric. Wire or other gauze, stiffened by thick strands or by vertical or radiating ribs, may be coated with liquid cement by brushing or dipping, and then tapped to clear the holes, these operations being repeated, with intermediate hardening of the cement, until the holes are of capillary size. Ebonite may also be used. If the electrode plates are ribbed or corrugated, they also have thickened edges. Passages

for gas and electrolyte are provided. In the production of O and H, a dil. soln. of NaOH or KOH or K_2CO_3 is used.

Chlorates. A. E. GIBBS. U. S., 1,173,346, Feb. 29. In making $NaClO_3$, a soln. of NaCl from the cup 6 passes to the anode compartment of the electrolytic cell 2. After electrolysis, the cathode liquor is pumped to the tank 10, and passes through the tank 13 to the tower 17, where it meets an ascending current of Cl supplied through the pipe 26 from the anode compartment of the electrolytic cell. The excess of Cl used forms $NaClO_3$, the reaction being promoted by heating if necessary. The liquor passes to the tank 20b and is circulated through the app. repeatedly until a sufficiently concd. $NaClO_3$ soln. has been formed. Fresh NaCl is added to the tank 10. Pptd. impurities, *e. g.*, $CaCO_3$ and $MgCO_3$, settle in the tanks 10 and 13. In making $KClO_3$, the latter is removed as a sludge at 14 or 15.

Electrical flame-arc furnace for oxidizing atmospheric nitrogen. H. BONNEVIE. U. S., 1,173,699, Feb. 29. Air is supplied from the chamber D to the flaming arcs C between electrodes B and the gases produced pass through flues of a tube boiler F just above the arc chamber. H and K are magnets which give a vaulted form to the arc flame.

Ferrosilicon. H. C. HARRISON. U. S., 1,171,719, Feb. 15. SiO_2 agglomerated with somewhat more C than required to reduce the SiO_2 is electrically smelted with Fe_2O_3 . The CO produced in the final stage of the smelting serves to reduce the Fe, in a preliminary stage, and is also used to preheat the charge. By the time the charge reaches the twyers its temp. is raised to 1500° and in the final stage of the process a temp. of 2000° is maintained. Cf. C. A. 9, 1278.

Reducing tin chlorides. F. MEYER and H. KIRSTEIN. U. S., 1,173,012, Feb. 22. $SnCl_4$ is reduced by passing it into the app. through the tube b, passing H in through the tube c and maintaining the temps. of the zones "A," "B" and "C" at 250° , $500-600^\circ$ and $600-1000^\circ$, resp. The Sn is gradually reduced as it passes to the hottest zone and excess of H and HCl escapes at the top of the app. The Sn flows off at d. In reducing $SnCl_2$, the tube b is omitted and H and molten $SnCl_2$ are both admitted

through the tube *c* (Fig. 1). TiCl_4 is reduced in the app. of Fig. 2 when supplied through the tube *b* with H fed through the tube *c*. Reduction to TiCl_3 is effected when the zone "C" is kept at 700° and to metallic Ti at $800\text{--}900^\circ$. Zone "B" is kept at 500° and a C rod *d* in zone "A" is kept at incandescence by elec. heating. *e* and *f* are lead-in wires.

Electric arc soldering. E. H. JONES. Brit., 21,822, Oct. 31, 1914. Arc soldering electrodes are coated with materials which form a cement on drying. Suitable materials are 3 parts of finely powdered slag sand, 1 part of slaked lime, and small quantities of a siliceous material such as silicate of soda, and H_2O . Or a ready made cement may be used with the siliceous material. The coating is extruded under pressure and may be made thin or removed on one side of the electrode to confine the arc.

Electric endosmosis; gelatin. GES. FÜR ELEKTRO-OSMOSE. Brit., 21,484, Oct. 24, 1914. Gelatin freed from salts, reducing agents, albumin, and fat by the process of 21,448, 1914, is used for the prepn. of photographic emulsions. Cf. C. A. 9, 1156.

Electric endosmose; gelatin, glue. GES. FÜR ELEKTRO-OSMOSE. Brit., 21,483, Oct. 24, 1914. A material yielding glue or gelatin, e. g., ossein or hide or leather waste, is purified from acids, salts, lime, and other substances by moistening it or suspending it in H_2O and subjecting it to an elec. current while between diaphragms, in the same way as glue itself is treated according to 21,448, 1914. The heat produced by the current, aided, if necessary, by additional heat and chemicals, may be utilized for simultaneously converting the material into glue or gelatin.

Electric endosmose; tanning. GES. FÜR ELEKTRO-OSMOSE. Brit., 21,190, Oct. 19, 1914. An electrolytic tanning or other impregnating process of the kind described in 19,849, 1914 (C. A. 10, 563), is modified to allow of preliminary purification of the impregnating liquid. Tannin exts. otherwise incapable of direct employment can thus be used. The tan liquor is placed between the cathode diaphragm and a third positive diaphragm sepg. the liquor from the hides. All the other compartments are filled with H_2O . The new diaphragm may be of leather, while the anode diaphragm may be of parchment paper, which is feebly negative. Acid and basic impurities collect, resp., in the anode and cathode compartments before the tannin passes through the positive diaphragm.

Electric endosmosis. GES. FÜR ELEKTRO-OSMOSE. Brit., 21,448, Oct. 23, 1914. Gelatin, glue, or the like, in soln. or in a softened condition, is purified and fractionated by elec. current between indifferent diaphragms impervious to glutin. Inorganic ions migrate through the diaphragms, while albuminoids are pptd. and may be sepd. In a modification, the anode diaphragm is of an electropositive substance, such as pig's bladder or gelatin, hardened by HCHO . Colloidal and other acids pass through this diaphragm, and albuminoids are partly deposited on it. Viscose or parchment, which

is feebly negative, is used for the cathode diaphragm. In another modification, an additional highly electronegative diaphragm of cotton, felt, burnt SiO_2 , or other material, and a body of H_2O , are placed between the negative diaphragm and the glue or like soln., to which may be added chemicals, such as acid salts, increasing the charge capacity on the positive side. Pure glue or the like passes into the H_2O compartment, the soln. thus obtained being, if desired, replaced by fresh H_2O after a time. The residual glue has a high viscosity. Impurities such as albuminoids, fats, and pigments partly migrate to the anode if the anode diaphragm is permeable. The albuminoids may be either rendered sol. again or sepd.; when dried they form a tough, elastic mass. Several additional diaphragms of selected potentials may be arranged between the glue and the electrodes to produce further fractionation.

Tungsten filaments. E. R. GROTE and J. W. H. REYNOLDS. Brit., 22,057, Nov. 5, 1914. A binder consists of gelatinous $\text{Al}(\text{OH})_3$, mixed with tungstic acid or a compd. such as Na tungstate or paratungstate. $\text{Al}(\text{OH})_3$ is dissolved in a soln. of tungstic acid in NaOH and heated until sticky, whereupon powdered W metal or compds. are incorporated, and the paste is squirted into filaments or made into rods to be drawn, the subsequent steps being ordinary.

Vapor lamp. EHRICH & GRAETZ and E. PODSZUS. Ger., 286,268, Mar. 17, 1914. The lamp is provided with two metallic electrodes and with vapors which are not generated by the electrode material. A constant flow of vapor is maintained upwards in the direction of the long arc, which is thereby rendered stable. This flow of vapor is obtained by providing in the lamp a condensible constituent, which is collected at cooler points and returned to the vaporizing chamber from whence it again passes upwards around the lower electrode, producing there an increased pressure.

Generation of light by highly heating solid refractory incandescent materials in the path of the electric current. J. E. LILIENFELD. Ger., 286,296, Mar. 15, 1912. This heating is effected in a gas under reduced pressure, through which high tension discharges are passed. O is used as the gas. A metal oxide, e. g., the Auer Ce-Th mixt., is used as the incandescent body.

LOUIS DERR.

Colloid chemistry and photography. LÜPPO-CRAMER. Frankfurt. *Kolloid-Z.* 17, 105-6(1915); cf. C. A. 9, 3178-9-80.—Vegetable gums, colophonium, shellac, turpentine or Canada balsam will act as a preservative for collodion plates, making it possible to use them as dry plates if added to the amount of 0.5% of the collodion emulsion; but as they will not prevent fogging they cannot displace gelatin or sugar as preservatives.
H. I. MATTILL.

Toning with cobalt sulfide. R. NAMIAS. *Rev. gen. sci.* 27, 72(1916).—The image is bleached in 5% $\text{K}_4\text{Fe}(\text{CN})_6$, washed, and toned in 2% CoCl_2 slightly acidified with HCl, then washed again 30 min. Development with a weak metol or metol-hydroquinone developer gives brown tones superior to the usual S tones, and the result is still better if, instead of development, the print is treated with 10% Na_2S . If the Co bath is followed by a hypo bath to remove the Ag, only the Co image remains; this gives the process ceramic possibilities, in view of the well known color effects produced by Co in vitrification.
L. DERR.

Artificial illuminants for use in practical photography. C. E. KENNETH MEES. *Trans. Illum. Eng. Soc.* 10, 947-62(1915); cf. C. A. 9, 3180.—The photographic efficiency of artificial illuminants depends upon their quality and upon their visual

efficiency, but must be considered from the point of view of the materials used, which are of 3 chief kinds: (1) panchromatic materials sensitive to the whole spectrum and used with filters to give a rendering similar to that seen by the eye, or for color photography; (2) ordinary materials having their max. sensitiveness in the blue-violet; (3) materials sensitive only to the ultraviolet. For panchromatic materials the efficiency of the illuminant will depend almost entirely upon its visual efficiency while for ordinary materials the chief point of importance is the efficiency in the blue-violet; but since the latitude and freedom from halation increase with shorter wave lengths it is better to use light sources having their max. near 400μ rather than near 470μ . Nearly all artificial illuminants have application in some branch of photography or other.

C. G. F.

Color photography. F. E. IVES. U. S., 1,173,429, Feb. 29. Color selection negatives are used, which may be made by resensitizing to red a plate previously sensitized to green and similarly making negatives from both the red-sensitized and from a green-sensitized plate (as originally prepd., without resensitizing).

Cinematograph for producing colored pictures. L. CASAR VAN RIPEN. Ger., 285,558, Apr. 5, 1913.

Frame for holding cinematographic films during developing, washing, drying. A. ZIMMERMANN. Ger., 285,215, June 15, 1913.

Developing apparatus for photographic plates. J. HEINEN and T. HEINEN. Ger., 285,214, Sept. 22, 1914. The app. is designed for daylight developing.

Sizing photographic paper. M. ROTH. Ger., 285,562, Dec. 25, 1912. The difficulty sol. or insol. fat soaps are employed as an addition to the size, thereby preventing the reaction between the Ag salt emulsion and the metallic impurities present in the paper fiber. This effect is enhanced if the insol. fat soaps contain still other compds. which tend to convert the sol. Ag salts into insol. or at least difficultly sol. salts. If these compds. are in themselves sol., they are nevertheless enclosed by the insol. soap, so that the conversion of the sol. Ag salts into the insol. salts occurs only at the points of contact proportional to the amt. of the penetrating sol. Ag salts, whereby a reverse action on the emulsion film itself, as by capillarity, is prevented. Such fat soaps may be employed also with finished paper, by applying them directly to the paper in combination with gelatin soln., or adding them to the dressing used in mfg. baryta papers. The preferred mixt. contains 2 parts gelatin to 1 part so-called fatty acid, and sufficient solvent to give to the mixt. a content of about 10% gelatin. The salts (bromides or chlorides, as well as acetates, tartrates, or citrates) may be incorporated with the prepd. soap mixt. or directly with the soaps as they are made.

Photography. M. ROTH. Brit., 21,884, Nov. 2, 1914. In prepg. paper for photographic purposes, use is made of emulsions of insol. or sparingly sol. fatty soaps prepd. with gelatin, rosin soln., etc., either in the fiber as a sizing in the paper-making machine, or in or upon the finished product. In addition, there may be added alkali chlorides or bromides or other compds. capable of pptg. the sol. Ag which has not been pptd. by the fatty acid of the soap. The emulsion can be added to a baryta surfacing medium.

6. INORGANIC CHEMISTRY.

H. I. SCHLESINGER.

Potassium metabisulfite. A. A. BESSON. Basel. Chem. Ztg. 40, 165-7(1916).—Eight com. samples are described. The SO_2 was detd. in the dry compd. and in fresh

and old solns. by titration with I, and with caustic soln. after oxidizing with I or with H_2O_2 in the cold without addition of alkali and in the warm with addition of alkali. The SO_3 was detd. before and after oxidizing with I and H_2O_2 . The conclusions are that $K_2S_2O_8$ is the correct formula for the normal compd.; that in the normal salt the SO_3 may be detd. iodometrically or alkalimetrically with equal accuracy, although the former is preferable because the com. salt may contain other acid salts or neutral salts with active SO_3 groups; that in titrating the SO_3 the salt should not be dissolved in H_2O , but the 0.1 N I added direct and the excess detd. after the reaction; that the % SO_3 falls 1.69-3.21 below the theoretical; that SO_3 is always present, the clearer the crystal the less the amt.; that the normal salt does not smell of SO_3 , but is slowly decomposed by atm. moisture with evolution of SO_2 . J. H. MOORE.

The system lead sulfate-sulfuric acid-water at different temperatures. A. D. DONK. Utrecht. *Chem. Weekblad* 13, 92-7(1916).—An investigation of the above ternary system at temps. from 0 to 200°, made to obtain information in regard to the formation of the compd. $PbSO_4 \cdot H_2SO_4$, met with in the evapn. of H_2SO_4 in lead pans. At 0°, as the H_2O content is increased from 0, first H_2SO_4 , then $H_2SO_4 \cdot H_2O$, is solid phase in the binary system; the concn. of $PbSO_4$ in the soln. is less than 0.1%, except at the invariant point $PbSO_4 \cdot H_2SO_4$, where it is 0.3%. Isotherms were also detd. at 50, 100, 150, and 200°; in each case the soly. of $PbSO_4$ is about 0.1% or less, except in solns. containing more than 90% H_2SO_4 ; the max. soly. found was 1.1% in 98.9% H_2SO_4 at 200°. $PbSO_4 \cdot H_2SO_4$ was not met with as solid phase in any portion of the system. GEORGE W. MOREY.

A rapid method of converting scrap platinum into chloroplatinic acid. J. B. TINGLE AND A. TINGLE. *J. Soc. Chem. Ind.* 35, 77(1916).—By alloying the Pt with a suitable base metal, the time necessary for converting it into chloroplatinic acid can be shortened so that a prepn. normally occupying days can be completed in a few hrs. For this purpose it is advantageous to use Zn, as this can be most easily sepd. from the Pt. The Pt is fused with Zn under a layer of some flux, the alloy thus formed being treated with dil. HCl in which the Zn dissolves, leaving the Pt as a black powder. The latter is almost instantly soluble in aqua regia. This soln. is evapd. to dryness, dil. HCl added and treated with a strip of pure Zn, by which means the Pt is pptd. out and may be sepd. from traces of Zn by thorough washing. The pptd. Pt dissolves at once in aqua regia. L. T. FAIRHALL.

7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAGH.

Microchemical toxicology. O. TUNMANN. *Apoth.-Ztg.* 30, 678-9, 686-8(1915).—A series of papers is promised under the above caption, a title chosen for the reason that the investigations, at first planned to cover only poisonous plant products, were gradually extended to include metals and volatile poisons as well as artificially prepd. toxic products, in short all substances treated in the toxicological practicum at the university and in handbooks on toxicology. The present paper deals with *aconitine* and its identification by means of micro-sublimation, the technic followed and cryst. products obtained being quite fully described. W. O. E.

Action of mercury salts on sheet aluminium. Application of this reaction in general analysis and toxicology for detection of mercury salts. S. MINOVICI AND E. GROZHA. *Bull. sci. acad. Roumaine* 4, 227-30(1916).—A few drops of Hg salt soln. (also Hg albuminate) on Al foil leaves in a short time an efflorescent residue, which grows rapidly in small stalagmites of $Al(OH)_3$. The reaction is sensitive to about 1:100,000.

Foreign salts do not interfere. The Hg salt is reduced as is shown by using red HgI_2 . This is changed into green HgI , then into metallic Hg. The authors propose this reaction as a test in general analysis and toxicology. L. H. CHERNOFF.

Metallic calcium and its use in gas analysis. A. SIEVERTS. *Z. Elektrochem.* 22, 15-8(1916); *J. Soc. Chem. Ind.* 35, 119-20(1916).—While some specimens of commercial Ca combine with N only above 800° , the majority exhibit a second zone of activity between 300° and 660° , with its optimum about 440° , at which temp. 2-4 g. pieces of the metal can be quantitatively converted into nitride without any difficulty; on raising the temp. the rate of absorption diminishes, becoming zero between 660° and 800° . S. designates these 2 kinds of commercial Ca as "inactive" and "active." The former can be transformed into the latter by melting and cooling slowly so as to produce a relatively coarse-grained cryst. structure; it then absorbs N even below 300° and above 650° . The reverse change is effected by chilling melted Ca from 840° . Mechanical powdering of the metal does not increase its reactivity but may render it "inactive." The varying "activity" of commercial specimens is obviously due to manufg. processes. No indications of polymorphic transformations were obtained with cooling curves. The absorption of H by com. Ca also depends on the cryst. structure of the metal, though no samples were found quite "inactive" towards H at all temps. below 800° . Samples which absorbed N only between 300° and 660° absorbed H only between 150° and 300° , and above 600° . Samples of coarse-grained cryst. structure reacted at the ordinary temp., the absorption rate increasing with temp. A superficial layer of hydride (or nitride) facilitates the further absorption of H (or N). Above the m. p. of Ca (810°) the absorption rate of either gas increases very rapidly with rise of temp. Ca nitride absorbs H and forms the compds., $\text{Ca}_3\text{N}_2\text{H}_2$ and $\text{Ca}_3\text{N}_2\text{H}_4$ (cf. Dafert and Miklausz, *C. A.* 4, 31; 8, 636), of which only the second undergoes appreciable dissociation below 600° . Measurements at 480° indicate that the compds. form solid solns. with each other. Ca nitride also absorbs CO_2 , CO, and CH_4 , with liberation of C. "Active" com. Ca can be applied to the detn. of inert (rare) gases in gas mixts., at temps. attained with a Bunsen burner. An app. devised for this purpose consists of a manometer open to the atm., with narrow glass tubes, and an easily replaceable absorption tube of 50-75 cc. capacity connected by a joint rendered air-tight with sealing wax; 3-5 g. pieces of Ca are used. The app. is first evacuated with the H_2O pump and then completely by heating the Ca. It is filled with the gas to be analyzed, and the pressure difference before and after absorption is measured at const. vol. and const. temp. The detn. of A in air, com. N or O, or even in crude A can be effected in about 1.5 hrs. For gases containing CO_2 , CO, or CH_4 , an absorption mixt. of Ca and Ca_3N_2 is used. For more exact analyses, e. g., detn. of inert gases in minerals, an app. provided with a spectral tube is used, and the pressure and vols. are measured. Cf. *C. A.* 3, 746; Brandt, *Z. angew. Chem.* 27, I, 424(1914). F. W. SMITHER.

The separation and determination of phosphoric acid as ammonium magnesium phosphate. H. LÉSCOEUR. *Bull. soc. ind. Nord France* 42, 93-7(1914); *Z. angew. Chem.* 27, II, 459(1914).—L. calls attention to Varrington's method in which the copptn. of Ca, Fe, and Al phosphates is prevented by the addition of citric acid (cf. *Ann. chim.* [4] 1, 447). Joulie's method of sepn. is described. L. has found by expt. that the phosphate ppt. always contains an excess of Mg, varying directly with the excess of precipitant (MgCl_2 or MgSO_4) used. To obtain a ppt. of theoretical compn., the ppt. obtained with an excess of the precipitant is filtered off, washed, dissolved in HCl, and repptd. by the addition of NH_4OH . F. W. SMITHER.

Determination of sulfur dioxide and sulfur trioxide in flue gases. R. J. NIXTELL AND E. ANDERSON. *J. Ind. Eng. Chem.* 8, 258-60(1916).—This method is adapted

to work in various departments of a smelter, such as multiple hearth roasting furnaces, the app. being capable of convenient transportation. After estg. the SO_2 by Hawley's method (C. A. 7, 461) the SO_2 is detd. in the same sample by aspirating through a measured excess of Na_2CO_3 soln., adding H_2O_2 , and titrating back with standard HCl .

H. M. LANCASTER.

Methods of determining iron and alumina in mineral phosphates. V. P. KOCHETKOV AND D. N. KASATKIN. *Is Result. Veget. Opylov Lab. Rabot* 9, 71-80 (1913); *Expt. Sta. Record* 34, 112-3.—Comparisons are reported of methods of quant. analysis of Viatka and Smolensk phosphates and of artificial mixts. of the principal salts found in natural phosphates for sesquioxides of Fe and Al. The methods compared were (1) Glaser's method, (2) pptn. of Fe and Al phosphates by Na acetate after neutralization of the acid phosphate soln. by Na_2CO_3 , (3) pptn. of the Fe and Al phosphates by NH_4 acetate, and (4) Grandeau's method of pptn. of the hydrates of the sesquioxides by NH_3 after treatment of the acid phosphorite soln. with acetic acid for the elimination of a large part of the Ca phosphate and by NH_4 molybdate for the elimination of the remainder of the H_3PO_4 . The method of Grandeau (4) was found to give the best results. Glaser's method (1) gave results slightly inferior; they are considered suitable for industrial analysis. The second method gave good results when an excess of acetic acid was used, but the third method apparently does not merit use.

E. J. C.

Improved method for determining iron in Prussian blue. J. E. HECKEL. *Drugs, Oils and Paints* 31, 328-9 (1916).—H. enumerates the sources of error in existing methods and proposes the following as a satisfactory procedure: Heat the sample in an open crucible gently at first, but ending with strong heat. It is unnecessary to use the blast lamp. Cool, and place the crucible and contents in a beaker. Add 25 cc. concd. HCl and 3 cc. SnCl_2 soln. and heat for 15 min. or until soln. is complete. Remove and rinse crucible. Transfer the soln. to a 500 cc. graduated flask, wash the beaker and make up to the mark with distd. H_2O . Concentrate a 100 cc. aliquot portion and reduce with SnCl_2 . Stir constantly, adding the material drop by drop from a buret until an apple-green color is produced—from chrome oxidized blues. For chlorate oxidized blues, the SnCl_2 is added until the yellow color completely disappears. At once pour in 50 cc. cold HgCl_2 soln. and 50 cc. MnSO_4 soln., dilute with cold H_2O to about 600 cc. and titrate with KMnO_4 soln.

E. W. BOUGHTON.

Contribution to the analysis of copper, aluminium and zinc alloys. H. GRAEFE. Hanover. *Chem. Ztg.* 40, 102 (1916).—Dissolve 0.5 g. borings in 15 cc. strong HNO_3 , dil., filter off any SnO_2 and exam. for SiO_2 . Warm the filtrate (about 150 cc.) to 60-70° and electrolyze for 30-40 min. with a current of 0.2-0.4 amp. at 2-3 v. Cu and Pb, if the latter is present, are deposited. Then nearly neutralize the soln., which now contains Al, Zn and Fe (if present), with solid KOH , but leave distinctly acid. Ppt. with Na_2CO_3 , wash the ppt. with hot H_2O , transfer to a 300 cc. beaker, dissolve with a very little H_2SO_4 (1:4), add a large excess of satd. KOH soln. till ppt. redissolves and electrolyze the soln. (about 150 cc.), best with a coppered gauze cathode at 700-800 r. p. m., beginning with 1 amp. and raising the current 1 amp. every 10 min. for 40 min. Wash the Zn ppt. without breaking the current, dry with alc. at a low temp. and weigh. Al and Fe in the soln. are detd. in the usual way. The method is rapid and accurate even with alloys containing 90% Zn and only 5-7% Cu and less than 5% Al.

J. H. MOORE.

The determination of titanium in ferrotitanium. G. RÖHL. Mülheim. *Chem. Ztg.* 40, 105-6 (1916).—Gravimetric and volumetric methods were tried out on the same sample of Fe-Ti; of the former, Gooch's method as modified by Thornton (cf. C. A. 6,

3245) was found to be the most rapid and accurate. The best volumetric method is a modification of Knecht's method with methylene blue as indicator, using a standard FeCl_3 soln., as follows: Intimately mix 0.5 g. of finely ground Fe-Ti with 2.5-3 g. Eschka's mixt. in a Pt crucible whose bottom is covered with a thin layer of the mixt., heat over a Bunsen burner for 30 min., then 1 hr. over a blast or Méker burner, moisten the cooled sintered mass with a very little H_2O in an Erlenmeyer flask, crush and dissolve in 200 cc. concd. HCl with warming. Then make the soln. to 500 cc., remove 100 cc. to a 500 cc. Erlenmeyer flask with a 2-hole stopper and Bunsen valve through which CO_2 is passed, add 60-70 cc. concd. HCl and reduce the Ti for 30 min. by adding 4 or 5 pieces of granulated Zn as fast as it is dissolved, then adding 3 g. Zn filings and after the violent evolution of H is over heating carefully just to the b. p. (the soln. must not boil). After the Zn is all dissolved disconnect the CO_2 tube and through the hole in the stopper add a few drops of dil. methylene blue soln. Then titrate the hot soln. at once with standard FeCl_3 soln., allowing the point of the buret to extend through the hole in the stopper. The blue end point is very sharp. Cf C. A. 7, 3581; 8, 308, 882.

J. H. MOORE.

A rapid method for the analysis of red lead and orange mineral. J. A. SCHAEFFER. *J. Ind. Eng. Chem.* 8, 237-8(1916).—Treat 1 g. of the sample with 15 cc. of HNO_3 (d. 1.2) and stir until all red color disappears. Add 10 cc. of a soln. of H_2O_2 made by mixing 1 part of 3% H_2O_2 with 3.5 parts of H_2O . Stir until almost all PbO_2 is decomposed, and then add a little hot water and stir again until all PbO_2 has dissolved. Dilute with hot H_2O to 250 cc. and titrate with standard KMnO_4 soln., having an Fe value of 0.005. A blank titration is made in the same manner. The difference in the titrations multiplied by 3.058 = % of Pb_3O_4 , or multiplied by 1.067 = % of PbO_2 . S. has devised a chart, a cut of which is shown, whereon the % of Pb_3O_4 can be read directly.

E. W. BOUGHTON.

Chromium oxide analysis. A. J. FIELD. *J. Ind. Eng. Chem.* 8, 238-9(1916).—The fusion of the sample with Na_2O_2 can be satisfactorily effected in a Pt crucible placed inside a larger porcelain crucible heated by a low flame. After the fused mass is dissolved in H_2O , boiling during 20 min. is more than sufficient to remove excess Na_2O_2 . The volumetric iodide method gives excellent results.

H. M. LANCASTER.

A method for the determination of alcohol in the presence of phenol. J. EHRLICH. *J. Ind. Eng. Chem.* 8, 240-1(1916).—Conversion of $\text{C}_6\text{H}_5\text{OH}$ into $\text{C}_6\text{H}_5\text{Br}_2\text{ONa}$ is simple and rapid. It prevents the contamination of the EtOH distillate and consequent interference with the usual pycnometer method.

H. M. LANCASTER.

The determination of nitrogen in organic compounds by the microchemical method and by the ordinary method. G. FISCHMAN. *Rend. accad. sci. fis. et mat. Napoli* [3] 21, 135-42(1915).—From the data given it appears that the results of microcombustion are more accurate than those of the macrocombustion. The precautions at first seem laborious but are much less so after practice. The former requires only about $\frac{1}{2}$ as much time as the latter and can be carried out with very much less substance. The details of technic cannot be briefly abstracted. E. J. WITZEMANN.

Alloys of silver and platinum and their analysis (KOIFMANN) 9. Non-corrosive "binding post" (LEAVENWORTH) 4.

The quantitative relations in the hydrothermal metamorphosis of the chief salts in the Stassfurt potash salt deposits. M. RÓZSA. Budapest. *Z. anorg. allgem. Chem.* 94, 92-4(1916); cf. *C. A.* 9, 2862.—A number of analyses showed that the compn. of the "hartsalt" layers at Stassfurt corresponds closely with that calcd. from the hydrothermal metamorphosis of the carnallite layers, after subtraction of the $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$. The same holds true of the kainitite layers, apparently excluding the hypothesis of intermediate stages. GEORGE W. MOREY.

Evaporation of brine from Searles Lake, California. W. B. HICKS. U. S. Geol. Survey, *Professional Paper* 98A, 1-8(1916).—1000 g. of brine from Searles Lake, Calif., were evapd. in stages on the steam bath at 78° and the deposited crystals were sepd. from the soln. by filtration. The filtrate was cooled to 30° and a second fraction of crystals was obtained. Seven such successive stages reduced the brine to about 55 g. and yielded 14 fractions of crystals; 7 deposited from the hot soln. and 7 deposited as the soln. cooled from 78 to 30° . Each fraction of crystals as well as the original brine and the final filtrate was analyzed. Most of the sulfate was deposited from hot soln. in the first few fractions, and more than 60% of the K was deposited as the soln. was cooled to 30° in the last 3 fractions. Tabulated results give the compn. of the crystals deposited, the % of each constituent deposited, and the changes in the compn. of the soln. during evapn. W. B. H.

Extension of the Montana phosphate deposits northward into Canada. F. D. ADAMS AND W. J. DICK. *Proc. Nat. Acad. Sci.* 2, 62-4(1916).—Two beds of phosphate rock were found in the Banff region near Stony Squaw Mountain, the larger bed showing a thickness of 2 ft. The specimen analyzed contained 54% of $\text{Ca}_3\text{P}_2\text{O}_8$. The search is to be continued. L. W. RIGGS.

Pneumatolytic hornfels from hill countries of Siak (Sumatra). H. A. BROUWER. *Proc. Akad. Wetenschappen* 18, 584-91(1915); cf. *C. A.* 9, 2049.—Polysynthetically twinned feldspars and untwinned ones, or feldspars showing cross-hatching, can each dominate so as to exclude the others. Crystals are often untwinned, and may show parallel extinction, and contain gradations from microcline to orthoclase. The lack of feldspathization in the contact rocks can be explained by crystn. at lower temps and pressure and less mineralizers—especially alkalis. R. L. SIBLEY.

Submarine solution of limestone in relation to the Murray-Agassiz theory of coral atolls. A. G. MAYER. Carnegie Inst. *Proc. Nat. Acad. Sci.* 2, 28-30(1916).—M. refers to the work of Dole, Drew, Tashiro, and Kellermann and Smith (cf. *C. A.* 8, 2766, 3545; 9, 1343, 1357). Since the validity of the Murray-Agassiz theory depends upon the rate of the soln. of limestone in atoll lagoons, expts. were made to det. the soly. of weighed pieces of the shell of the mollusc *Cassia*. The specimens used had a sp. gr. of 2.88 and areas ranging from 57.6 to 85 sq. cm. Losses were detd. by subjecting pieces of shell to the action of sea water for a year under varying conditions, and, to approach most nearly the natural conditions, a 15.22 g. piece was placed in a 15 liter bottle into which the tide could ebb and flow, while shielded from light to prevent the growth of plants. This bottle was deposited between tides surrounded by open sea.

at Tortugas. The shell lost 0.047 g., or a superficial thickness of 0.0019 mm. in 1 year. Taking the rate of this expt. as the max. rate of soln. of CaCO_3 by sea water, over 19 million years would be required to dissolve a layer of 20 fathoms, this being the av. depth of atoll lagoons. As most, if not all, such lagoons have been formed since the beginning of Tertiary times, it is apparent that they owe their origin to other agencies than the soln. of CaCO_3 by sea water. In fact CaCO_3 is being pptd. from the sea water of the Florida and West Indian regions.

L. W. RIGGS.

9. METALLURGY AND METALLOGRAPHY.

WILLIAM BRADY, WILLIAM T. HALL.

The chemistry and metallurgy of tungsten. M. L. HARTMANN. *Pahasapa Quart.* 5, 25-34(1916).—An excellent, concise review. A bibliography is appended.

F. W. SMITHER.

Counter-migration of pulp and solution in cyanidation and acid leaching. B. MACDONALD. *Met. Chem. Eng.* 14, 283-4(1916).—An explanation is given of the manner in which the sepn. of pulp and value-bearing soln. is effected in the Parral tank system. It is suggested that this tank might be used to advantage in the acid leaching of copper ores, since it would obviate the necessity of filtering the extd. ore.

E. A. TSCHUDY.

Coal, coke, and limestone efficiency in blast furnace operation. B. F. BURMAN. *Met. Chem. Eng.* 14, 256-8(1916); cf. *C. A.* 9, 3046; 10, 737.—*Limestone efficiency:* The value of a limestone is dependent on the amt. of its net available base. A pure limestone containing 100% carbonates may be considered 100% efficient, and another with less carbonates as less efficient. S and P should be kept to minimum amts. In making the efficiency detns., Al_2O_3 should be considered equal to SiO_2 as acid, and MgO equal to CaO as base. The difference between 100 and summated acid thus found should be considered as summated carbonate. If the slag runs with summated acid equal to the summated base, the wt. of useless stone must be summated acid plus the wt. of that CO_2 which accompanies the base of the same wt. as the summated acid. The aid of the laboratory must be enlisted to improve or keep up the quality of limestone at the quarry. Standards are necessary for figuring the relative value of the limestone, and the av. analysis of the material for the past year should be adopted as a basis for comparisons. As S plays such an important part in blast furnace operations, where its presence in the slag must not exceed a certain limit, more or less dependent on local conditions, great care must be taken to produce sufficient quantities of slag in order to keep the S on hand in a safe soln. For calculating the relative cost of anything entering the blast furnace it will therefore be convenient to have standard figures on hand relative to the amts. of coke, flux, etc., necessary to put a unit of S into the slag, thereby producing a standard S soln. The S in question is the surplus amt. left over after the slag on hand has been satisfied. Methods of making the calcs. are given.

The dry blast in the manufacture of iron and steel. ANON. *Engineering* 101, 125-8, 152-3(1916).—A review and discussion together with descriptions and illustrations of plants.

F. W. SMITHER.

The Newcastle steel works, New South Wales. ANON. *Iron Coal Trades Rev.* 91, 275-7(1915).—A description of a new plant producing 170,000 tons of steel annually.

H. O. OLIN.

The Washoe reduction works, Anaconda. II. L. S. AUSTIN. *Mining Sci. Press* 112, 304-9(1916); cf. *C. A.* 10, 739.—A detailed description with illustrations

flow sheet, etc., of the coarse concentrator and flotation plant. The system consists of graded crushing with jig concn. for the removal of coarse concentrates, and a tailing that is progressively crushed, no part of the tailing being wasted, but all of it finally recrushed for flotation. The flotation consists in finely grinding the concentrator-tailing, adding oil and acid to the pulp, agitating this mechanically (finally with the aid of air), skimming the mineral-bearing froth produced (this being the concentrate), settling it out in Dorr thickeners, and from them removing the thickened underflow for filtration by the Oliver filters. The resultant product, still retaining 10% H₂O and containing 6% Cu, is sent to the smelter. F. W. SMITHER.

Refining cupriferous precipitate. J. A. PEARCE. *Mining Sci. Press* 112, 270-2 (1916).—The Argo Mill, at Idaho Springs, Colo., treats ores containing 3-4% of Cu which interferes with the refining of the ppt. By the ordinary method of refining (acid treatment, drying and melting) the bullion obtained is never better than 750 fine, and frequently as low as 550. Cu elimination by a wet method has proven satisfactory. The sludge from the zinc boxes is treated with an excess of H₂SO₄ until action ceases, and then finely pulverized pyrolusite is added (4-6 lbs. remove 1 lb. of Cu). The charge must be kept distinctly acid, hot, and agitated. The nascent O evolved oxidizes the Cu and the CuO formed immediately dissolves in the excess of acid. Due to the presence of finely divided electropositive Cu in suspension, the Ag is at once reprecipitated as metallic Ag. With removal of the Cu the Ag makes its appearance in the soln. and constitutes the end point of the reaction, which is complete in a few minutes. Some Ag goes into soln. but this can be reprecipitated by adding some of the original cupriferous ppt. After precipitation of the Ag the charge is drawn into the filters, washed, dried, and melted. All app. (tanks, pipes) should be lead-lined and centrifugal pumps with brass runners are preferable. The filtrate assays 0.005 oz. Au, 0.003 oz. Ag per ton. It is treated with scrap iron while hot to remove the copper, and then goes to waste. Bullion that assayed 500 to 750 fine now assays better than 900. By the process Pb is not removed, and at present, 95% of the base metal in the bullion consists of Pb. E. A. TSCHUDY.

International smelter at Miami. R. W. KERNS. *Eng. Mining J.* 101, 421-4 (1916).—A detailed description with illustrations of the works of the Intern. Smelting Co., at Miami, Ariz. It is essentially a reverberatory smelting plant and handles the concentrates from the Inspiration and Miami mills. The concentrates, largely produced by the flotation process, are very fine and carry more than 10% of H₂O and about 40% Cu; they resemble black mud, their stickiness and fineness being detg. factors in the design of the plant. No roasting action is permitted, as it is necessary to ship sulfide ore from Bisbee in order to obtain sufficient S for mat formation. Two Cottrell pptn. plants are used, one for the drier plant and one for the converter gases. F. W. SMITHER.

Preferential flotation of galena and blende. ANON. *Australian Mining Eng. Rev.*; through *Met. Chem. Eng.* 14, 279(1916).—A description of the sepn. of galena and blende at the Sulphide Corporation works, Broken Hill. The Hebbard-Harvey under-drive machines (capacity about 4000 tons per week) are used. The flotation plant handles tailings (carrying 4.2% Pb and 18% Zn) from the Pb mill, where the major portion of the galena is sepd. The pulp is first agitated with eucalyptus oil; the froth carries 57% Pb, the residue 3% Pb and 18.5% Zn; in the next flotation treatment oil and acid are used, the concentrate assaying 6% Pb and 47.5% Zn. The final tailings contain 1% Pb and 2% Zn. The process is conducted in the cold. It effects the recovery of an additional 15% of Pb and Ag as compared with the process previously used. The new process permits the fine tabling in the Pb mill to be discontinued. Rhodonite forms the principal obstacle to successful tabling (its d. being be-

tween that of galena and blende), but flotation gets rid of it as well as of other gang matter, and makes possible an easier sepn. of the 2 minerals in subsequent tabling operations.

F. W. SMITHER.

The determination of grain size in metals. Z. JEFFRIES, A. H. KLINE AND E. B. ZIMMER. Case School Applied Science. *Bull. Am. Inst. Mining Eng.* 1915, 2359-69. —A method has been developed, by means of which grain size can be detd. in much less time than by the planimetric method. The method has for its object the rapid detn. of the number of grains included within a circular portion of an image. The grains completely included need no correction factor but the boundary grains lie partly within and partly outside the field of observation. The grains completely within the circle are first counted and checked. Then the boundary grains are checked with a different mark and counted. If the area of the included grains is known by planimetric measurement, it is easy to compute the av. area per grain. The results of 187 detns. showed the max. error to be 6.4%, the av. error 2.1% and the av. algebraic deviation from the planimetric measurements $\pm 0.25\%$. It is believed that the intercept method and Heyn's method are less accurate.

W. T. HALL.

The principles underlying methods for the production of malleable iron. KART. BRISKER. *Montan. Rundschau* 7, 563-8(1915); through *Chem. Zentr.* 1915, II, 765-6. —All malleableizing processes, either upon solid or on liquid cast Fe, are concerned first of all with the mass of metal itself and from it difficultly fusible scales are formed. These oxides combine with SiO_2 , which is always present, forming readily fusible Fe silicates which can dissolve SiO_2 and FeO. The dissolved FeO, which is present in every freshly formed Fe-silicate slag, diffuses into the fluid Fe and gives up its O to the foreign substances present, forming Fe silicates, Mn silicate, FePO_4 , etc., which pass into the slag with liberation of considerable heat as a result of the chemical action. The malleableizing action of the FeO on C requires heat and can only take place when sufficient heat has developed. Then the CO that is formed causes the melt to swell or "boil." If earth bases are present, the conditions are favorable for their uniting with all the SiO_2 and P_2O_5 ; the acid constituents are thus made inactive and the metal oxides are not reduced. If the oxidation of the C takes place with sufficient supply of heat, finally not only the metal oxides but even the silicates and phosphates are reduced. Consequently, if there is not sufficient metal or earth bases to combine with the acids present, the P can go back as such into the liquid metal; the certain removal of this element, therefore, is accomplished only when a slag rich in metal or lime is present. The FeO remaining in the metal mass after the completion of the malleableizing process must be reduced by the addition of metallic Mn or, in some cases, Si or Al. The removal of the S from the Fe is a result not of the oxidation action but of the liquation of the metal sulfides, which, as far as the fluidity of the slag permits diffusion, pass into it. To prevent any return of the S to the metal bath, the sulfides must be destroyed by combustion or some constituent, such as CaO, must be present in the slag which will hold the S firmly.

W. T. HALL.

The effect of nitrogen on steel. B. STRAUSS. *Iron Age* 97, 432-3(1916); cf. C. A. 9, 433. 905.—At the Krupp plant in Essen, N in acid and basic Bessemer steel was found to vary from 0.012 to 0.30% and in open hearth steel from 0.001 to 0.008%. In nitrogenizing steel with NH_3 , the action begins at 300° and is most active between 600° and 800° . Above 800° the rate of absorption decreases. The limit of absorption is 11.1%, corresponding to Fe_4N_3 . Pure electrolytic Fe treated in NH_3 for 12 hrs. at 750° shows under the microscope a shell of nitride, then a structure resembling pearlite, and then ferrite crystals crossed by needles. The pearlite structure is due to both N and C; the latter comes from pyridine in the NH_3 fumes. The needles are supposed to be slip bands due to the brittleness of the ferrite caused by N. Low C

steel annealed in NH_3 at 700° absorbed N up to 0.10% in 24 hrs., 0.11% in 48 hrs., 0.16% in 72 hrs. and 0.22% in 96 hrs. The elastic limit and ultimate strength were slightly increased and the elongation and reduction of area decreased. N may be removed by heating *in vacuo* at 620° or in H at 400° . In thin sheets blow holes may be caused by the decompn. Nitrides of some of the alloying elements such as Si, Cr, etc., are formed on heating the steel to 800° . CARLE R. HAYWARD.

Vacuum-fused iron with special reference to effect of silicon. T. D. YENSEN. *Bull. Am. Inst. Mining Eng.* 1916, 483-512; cf. C. A. 9, 906, 1892.—The electrolytically refined Fe used in the investigation, containing less than 0.01% C and about 0.01% Si, was melted in a vacuum furnace with the alloying Si under a finishing pressure of 0.5 mm. Hg. Si, like B, besides forming a solid soln. with Fe, reduces any FeO that may be present. The max. tensile strength of the vacuum-fused alloy is 105,000 lbs. per sq. in. with a Si content of 4.5% while its limit of forgeability lies between 7 and 8% Si, except that between 2.50 and 2.60% Si there is a critical state of extreme brittleness which corresponds to the compn. Fe_{10}Si . From the standpoint of magnetic properties the optimum Si contents are 0.15 and 3.40% and the most favorable annealing temp. 1100° . The max. permeabilities for both these alloys are above 50,000 and the hysteresis losses for B max. = 10,000 and 15,000 are 300 and 1000 ergs per cc. per cycle, resp., values $\frac{1}{8}$ and $\frac{1}{8}$ of the corresponding loss for com. Si steel. The sp. elec. resistance increases about 13 microhms for the first % of Si added and for each additional %, 11 microhms. H. L. OLIN.

A chemical explanation of the effect of oxygen in strengthening cast iron. W. MCA. JOHNSON. *Bull. Am. Inst. Mining Eng.* 1916, 233-5; *Iron Age* 97, 309 (1916).—The work of J. E. Johnson, Jr. (cf. C. A. 9, 194) shows that cast Fe with an O content of 0.06% has a breaking strength of 3,500 lbs. per sq. in. while that with 0.01% has a strength of only 2,500 lbs. Photomicrographic evidence shows that the graphite particles of the first are dense and spherical while those in the second are flaky. The author explains these conditions by the postulate that the particles of any ppt. are made denser and harder by the presence of a reagent having a solvent action on the ppt. and cites as an example the coagulation of BaSO_4 in a soln. having an excess of HCl through the solvent action of the latter and the reformation of BaSO_4 in larger crystals. Similarly O acts on C, forming CO, which is dissolved in the Fe. H. L. OLIN.

The effect of carbon on the physical properties of heat-treated carbon steel. J. H. NEAD. *Bull. Am. Inst. Mining Eng.* 1915, 2341-58.—The expts. described were undertaken at the Watertown arsenal with a view of detg. the influence of C on the tensile and impact properties of steel. The original plan was to investigate a series of steels with varying C content over a wide range of heat treatments with regard to static tensile qualities and resistance to shock. The Charpy tests and metallographic examn. have not been completed but all the heat treatments and the static tensile tests are finished. A series of steels was prepd. with C varying from 0.14 to 1.46%, with approximate increments of 0.1% C, excepting the 0.9 and 1.1% C steels. The Mn varied from 0.20 to 0.67%, as is normal for commercial steels. With each heat treatment, 1 specimen was reserved for the tension test and 4 for the Charpy impact bending test. The specimens were tested: (a) as received, hot-rolled; (b) after annealing; (c) hardened in water; (d) hardened in oil and drawn at 375° ; (f) hardened in oil and drawn at 460° ; (g) hardened in oil and drawn at 560° ; (h) hardened in oil and drawn at 650° . As regards the max. strength of the specimens, it was found that this was reached in the annealed condition at the eutectoid compn. (0.83% C). With heat-treated steels, however, the falling off in strength does not begin until 1.2% C is present. The tensile strength curves show a rapid rise with increasing C to eutectoid compn., then a less rapid rise to 1.2% C, followed, as a rule, by a slight fall with

increasing C. Except in the hot-rolled condition, the unit stress of the yield point reached a max. at the eutectoid compn., falling off slightly or remaining constant with more C. The curves for Brinell hardness are very similar to those of tensile strength. In general, the curves for elongation and contraction show decreasing values with increasing C. The tendency of the curves is to be concave upward but they are straighter in the heat-treated than in the hot-rolled steels. Twenty-four photomicrographs show the characteristic structure of 12 steels as received, hot-rolled and normalized, or annealed, from 1000°. In the case of the hot-rolled steels, the structures consist of sorbito-pearlite and ferrite for the hypo-eutectoid steels and sorbito-pearlite with cementite for the hyper-eutectoid steels. With the annealed specimens, the grains are considerably larger and the constituents are pearlite and ferrite for hypo-eutectoid steels and pearlite and cementite for hyper-eutectoid steels.

W. T. HALL.

Proposed revisions in present standard specifications for steel and steel products. ANON. *Proc. Am. Soc. Testing Materials* 15, Pt. I, Appendix 2, 111-4 (1915).—Changes to be applied to the 1914 year-book. D. B.

Report of committee A-1 on finishing temperatures of rails. E. F. KENNEY, *et al.* *Proc. Am. Soc. Testing Materials* 15, Pt. I, Appendix 1, 91-110; Discussion, 115-20 (1915).—From actual tests it seems that there are not such decided differences in the quality of rails rolled at different temps. as the theory indicates. It does not seem justifiable to go to the expense of detg. finishing temps. any more accurately than possible with the shrinkage clause. D. B.

Neglected phenomena in heat treatment of steel. M. E. LEEDS. *Proc. Am. Soc. Testing Materials* 15, Pt. II, 5-26 (1915); see C. A. 9, 3210. D. B.

Experiments on the rusting of iron in water which has been softened by the permutite process and means for preventing corrosion. O. BAUER AND E. WETZEL. *Mitt. k. Materialprüfungsamt.* 33, 1-29 (1915); through *Chem. Zentr.* 1915, II, 499-501. —The corrosive effect of softened water was compared with that of ordinary tap water. Clean, polished plates of cast Fe and ingot Fe were used for the expts. The cast Fe contained 3.7% C (3.08% graphite), 2.40% Si, 0.89% Mn, 0.66% P, 0.09% S and 0.07% Cu. The ingot Fe contained 0.04% C, 0.01% Si, 0.59% Mn, 0.03% P, 0.03% S and 0.16% Cu. The expts. were carried out at room temp., at 50° and at 80°. In each case 2 series of expts. were performed with each metal and with each water; in one series the water was changed every working day and in the other the plates of metal were kept immersed in the same portion of water during the entire duration of the expt. (25 days). The polished metal strips were weighed at the beginning and again at the end of the expt. after brushing off all the rust. In the expts. at room temp. in which the water was renewed frequently, there was but little difference in the extent of corrosion observed with either material or either water, approx. 0.06 g. being lost by corrosion in every case. At 50° and 80°, however, both the cast Fe and the ingot Fe were attacked more by the softened water than by tap water. The water was kept at these temps. only during the working day and loss of water was prevented by use of condensers. The original plates weighed from 19.35 to 23.51 g. in the case of cast Fe and 7.77-9.91 g. in the case of ingot Fe. The losses in wt. at 50° were about the same as at 80° but approx. 3 times as much as at room temp. When the water was not renewed, the cast Fe was more strongly attacked at room temp. and at 50° and the ingot Fe was in every case more strongly attacked by the softened water than by tap water. The attack by the softened water was always more localized than in the case of tap water, which caused a fairly uniform attack. The cause of the corrosion is primarily the presence of dissolved oxygen. This dissolved O will

react with Na_2SO_3 and, for this reason, corrosion may be prevented by adding Na_2SO_3 . Tap water when treated with Na_2SO_3 soon lost all its dissolved O but the softened water reacted much longer. Corrosion expts. were carried out with introduction of air at room temp., in the absence of air at room temp., at 50° and at 80° , and also under 20 atm. pressure. The results showed that there was no tendency to corrode as long as unused Na_2SO_3 is present, but when this is completely oxidized to Na_2SO_4 , corrosion at once starts.

W. T. HALL.

Investigation of the behavior of iron in the presence of water and aqueous solutions in steam boilers. E. BOSSHARD AND R. PFENNINGER. Zürich. *Chem. Ztg.* 40, 5-6, 46-8, 63-4, 91-2 (1916).—Expts. were made in a specially constructed boiler on 7 pieces of boiler plate, analyses of which are given. The expts. lasted 24 hrs. at about 15 atm. pressure, and were made with freshly distd. H_2O , distd. H_2O containing O and CO_2 in soln., city H_2O , and with these containing, as a rule, 0.1, 1.0, 5.0, 10.0% Na_2CO_3 and up to 50% NaOH ; also with 1.0% solns. of Na_2CO_3 , NaOH , NaCl , NaNO_3 , Na_2SO_4 , CaCl_2 , $\text{Ca}(\text{NO}_3)_2$, CaSO_4 , MgCl_2 , $\text{Mg}(\text{NO}_3)_2$, and MgSO_4 , with 1.0% solns. of NaCl , NaNO_3 and Na_2SO_4 in the presence of varying amts. of Na_2CO_3 and with NaHSO_3 with and without Na_2CO_3 . The data are fully tabulated. The conclusions drawn are: CO_2 -free H_2O has the least action; all the compds., especially chlorides and Mg salts, attack the Fe, but when more than 10% Na_2CO_3 is present the action is reduced; 1.0% NaOH gives the best protection; 17.44% of the total alkali in a Na_2CO_3 soln. at 15 atm. for 24 hrs. was found to exist as NaOH , and 72.66% at the end of 96 hrs. This explains the protective action of Na_2CO_3 . NaHSO_3 in small amts. (0.6%) protects Fe; larger amts. are injurious even in the presence of Na_2CO_3 . J. H. MOORE.

Segregation in gold bullion. JAMES H. HANCE. *Bull. Am. Inst. Mining Eng.* 1916, 299-326.—The investigation described was undertaken with the view to det. the cause of frequent irregularities in the assay of cyanide bullion. In alloys of Au with basic metals, notably Pb and Zn, the Au segregates toward the central and lower portions and the bar cannot therefore be assayed with accuracy. If the base metal content is less than 30% the addition of Ag produces a homogeneous soln. and this expedient is suggested as a means of overcoming the difficulty, although it does not solve the problem.

H. L. OLIN.

The alloys of silver and platinum and their analysis. I. KOLFMANN. *Arch. sci. phys. nat.* 40, 12, 509-13 (1915).—In preparing these alloys by cupellation of weighed amts. of Ag and Pt, some Ag is lost. To prepare alloys of definite compn. it is better to fuse weighed amts. in a crucible with NaCl . It was found impossible to form alloys richer than about 5% in Pt. When treated with concd. HNO_3 all the alloys, ranging from 0.2 to 5% in Pt, left a black residue, more or less bulky, according to the Pt content, and gave a brown soln. of colloidal appearance. The residue, when treated with H_2O , gave a similar brown soln. and disappeared completely. The more concd. the acid the greater is the residue. It was apparent that there was no true soln. of Pt because Pt could be sepd. by centrifugalization. The residue was found to consist of pure Pt. Thus it is impossible to attack a Ag-Pt alloy and obtain a partial soln. of the latter; nor is it possible to sep. Ag from Pt by this means. The presence of AgNO_3 was found to have no effect in the formation of the colloidal soln. D. B.

Muffle furnace for heating metals. T. W. MUCKLE. U. S., 1,172,222-3, Feb. 15.

Ore-roasting furnace. H. T. BENSON. U. S., 1,171,583, Feb. 15.

Ore-roasting furnace. W. H. MOTTER. U. S., 1,172,479, Feb. 22.

Ore amalgamator. A. ALLEN. U. S., 1,172,099, Feb. 15.

Ore amalgamator. K. SENN. U. S., 1,172,171, Feb. 15.

Treating complex zinc ores. C. C. TITUS and W. J. BARENSCHERR. U. S., 1,173,467, Feb. 29. Zn ores which may contain Fe, Mn, Au, Ag, Ca, Mg, Pb or Cu, are chloridized, leached and the soln. obtained is treated with oxidized Zn ore to ppt. Fe and Mn. Zn is used to ppt. Au, Ag, Cu and Pb if present and Zn is pptd. as basic carbonate by the addition of NaCl and Na₂CO₃ soln. formed by carbonating a soln. formed by electrolysis of NaCl. Any Ca and Mg present are pptd. as carbonates after sepn. of the Zn carbonate and the exhausted liquor is electrolyzed for further use in the process.

Obtaining zinc from ores. F. C. W. TIMM. U. S., 1,172,321, Feb. 22. Air is passed through a hot mixt. of carbonaceous fuel and roasted Zn blende or similar Zn-bearing material for a short time. The charge is then remixed evenly and the passage of air continued to drive off additional Zn and obtain a sintered residue.

Obtaining zinc from a liquid slag bath. F. THARALDSEN. Ger., 286,228, Mar. 28, 1914. Addition to 261,188 (C. A. 7, 3310). The app. specified in the parent patent is modified in that under the hearth is provided a net-work of canals connected laterally with chambers from which the accumulated Pb alloy is tapped from time to time. In this manner the Pb alloy is prevented from strongly attacking the floor of the furnace hearth and opening up holes through the joints by corrosion, through which the Pb may escape. The sepn. of the Pb and Zn may be effected by remelting. Upon charging the slag into the furnace, Pb is added in such quantity that the chamber is filled to the height of the bottom of the hearth, so that the canals may not be stopped with slag.

Separation of mixed sulfide ores. R. T. D. WILLIAMS. Can., 165,390, Oct. 12, 1915. The finely ground ore is mixed with H₂O containing in soln. bleaching powder and a small proportion of a frothing agent, the mixt. is agitated to form a froth and the froth sepd.

Concentrating ores. L. BRADFORD. Brit., 21,880, Nov. 2, 1914. A process for the preferential sepn. of PbS or pyrites or both from ZnS consists in submitting the ores to flotation in an acid medium which wets the ZnS particles so that they sink while the PbS or pyrites particles or both are permitted to float, such medium consisting of an acid soln. to which is added a small quantity of a reducing gas, or a soln. of such gas, or a substance capable of evolving a reducing gas, such as thiosulfates, sulfites, bisulfites, sulfides, or polysulfides; *e. g.*, the medium may be a dil. soln. of SO₂. A frothing agent is used in cases in which a reducing gas is introduced; when the reducing gas is generated in the medium by reaction, a frothing agent need not be used. In some cases, the ore may be digested with H₂SO₄ and reducing agent before effecting the flotation operation. When the concentrate of PbS or pyrites or both has been ob-

tained, the ZnS may be floated after treatment of the medium by the addition of an oxidizing agent, or by agitation with steam and air, or by draining the residues and resubmitting them to flotation. Cf. *C. A.* 10, 585.

Separating and dressing mixtures in the electrostatic field. J. KRAUS. Ger., 285,209, Feb. 5, 1914.

Recovery of tin from tin scrap. G. O. SEWARD and F. VON KÜGELGEN. U. S., reissues 14,070-1, Feb. 15. See original patent 851,946; *C. A.* 1, 2040.

Dephosphorizing pig iron. P. L. T. HEROULT. U. S., 1,172,597, Feb. 22. Blast-furnace pig Fe high in P is treated in an elec. furnace with basic slag containing Fe oxide at a temp. just high enough to keep the slag molten and cause it to combine with the P in the Fe, without changing materially the % of C.

Alloys. L. GOLDMERSTEIN. Ger., 286,556, Apr. 15, 1913. Cf. Brit., 7,103, 1913 (*C. A.* 8, 3005). The alloys are prepd. by fusion, while at the same time the melt is freed from impurities such as P, S, and the like.

Reducing hysteresis of sheet metal alloyed with silicon. O. GRAEF. U. S., 1,173,951, Feb. 29. The permeability of plates or sheets of Si alloys is increased and the hysteresis loss reduced by annealing, pickling in a dil. acid soln., neutralizing and drying.

Iron united to copper-aluminium alloy. I. LANGMUIR. U. S., 1,171,856, Feb. 15. Fe or steel is united with an alloy of Cu with Al in an atm. of H by use of a cryolite flux at a temp. but slightly above the m. p. of the alloy. A firm union of the metals is effected which renders the composite article susceptible to mechanical working.

Copper-clad steel or iron. W. M. PAGE and W. TASSIN. U. S., 1,171,637, Feb. 15. A Cu-clad billet of Fe or steel is heated to nearly the m. p. of Cu and then rolled between blunt-edged oval rollers to reduce it to wire rod size while maintained at a temp. of 700-900°. Cf. *C. A.* 9, 591.

Coating aluminium or iron with other metals. F. MOENCH. U. S., 1,172,160, Feb. 15. An elongated vessel containing Pb, Sn or Zn to be used as the coating metal is heated near one end to a temp. sufficient to melt a portion of the metal adjacent this end and the articles to be plated, e. g., Al sheets, are plunged into the molten metal and rubbed against the semi-fluid metal at the junction of the molten and still unmelted metal and then withdrawn through the molten metal. Fe may be similarly coated with Al.

Annealing, tempering or hardening metals. F. L. BISHOP. U. S., 1,171,832, Feb. 15. Bar steel or other metal in the solid state is heated to 750-800° and subjected to the magnetic field of an a. c. while protected against oxidation, to alter the molecular structure of the metal at a lower temp. than would be effective without the action of the magnetic field.

Pickling and scouring plates. J. A. PARKER and A. PARKER. Brit., 21,621. Oct. 28, 1914. A rocking vessel for holding the plates is specified.

10. ORGANIC CHEMISTRY.

CHAS. A. ROUILLER.

Preparation of ethyl bromide. ALFRED HOLT. Liverpool. *J. Chem. Soc.* 109, 1-2 (1916); cf. Weston, *C. A.* 10, 43.—The object of the method is to obtain the greatest possible amt. of EtBr from a given weight of KBr or NaBr, a moderate waste of alc or H₂SO₄ being relatively unimportant, owing to the prevailing high price of the bromides. 900 cc. H₂O are gradually added to 1500 cc. H₂SO₄ and, after cooling, 1500

cc. abs. alc. run in, taking care to prevent too great a rise in temp. When cold, 1100–1200 g. KBr are added. (If the equiv. amt. $\text{NaBr} \cdot 2\text{H}_2\text{O}$ is used, the vol. H_2O added to the acid is slightly diminished.) The whole mixt. is then heated on a sand bath in a 4 l. flask at the lowest temp. at which EtBr will distil over, the process taking 8 or 9 hrs. The EtBr is caught in H_2O , washed with this, and dried over CaCl_2 . Owing to the fact that Et_2O and EtBr form a const. boiling mixt., the best criterion of the purity is the d. Yields: 90–96%, based on the anhydrous bromide used. Practically no HBr distils over when this method is used. M. HEIDELBERGER.

Cholesterol and coprosterol. III. The ozonides of cholesterol. IV. The action of bromine on cholesteryl benzoate. CHARLES DORÉE AND LIONEL ORANGE. *Borough Polyt. Inst., London. J. Chem. Soc.* 109, 46–55(1916).—The contradictory and uncertain results obtained by others in studying the action of O_3 on cholesterol (A) led the authors to reopen the subject. The "ozone number" method as used by Fürth and Felsenreich (*C. A.* 9, 2881) is valueless, as CHCl_3 , which they used as solvent, is strongly attacked by O_3 . The ozonized O was passed through H_2SO_4 and then 5% aq. NaOH to remove the O_4 present. The final concn. of O_3 was 0.8%, and this was passed into a suspension of (A) in HOAc at the rate of 1 mol. per hr. (0.12 g. per g.) (A). To test the extreme action of O_3 , it was passed through the soln. for 24 hrs. per g. (A). An equal vol. petr. ether was added and the whole poured into twice the vol. of H_2O , the ozonide sepg. as a clot. This was added to the alkali-washed Et_2O ext. of the aq. layer, dissolved in a little Et_2O , and pptd. with light petroleum. This was repeated several times, after which the viscous clot was dried in a high vacuum, whereupon foaming took place, and the product formed a brittle solid which could be easily powdered. The analysis indicated the addition of O_6 ; $[\alpha]_D^{18}$ 31° . All the other ozonization expts. mentioned below were worked up in the same way. Using a shorter ozonization period (3–10 hrs. per g.) and no NaOH washing soln. values were obtained indicating the addition of 6–7 atoms O; $[\alpha]_D^{18}$ 21° . The use of acetone as solvent did not change these figures. In expts. in which the ozonization was stopped as soon as the (A) went into soln. (1.5–4 hrs.), washed O_3 gave products averaging 3 atoms added O, $[\alpha]_D^{18}$ 43° , while crude O_3 gave products with 4 atoms O and $[\alpha]_D$ varying from 23° to 35° . Limited action of O_3 (passed first through H_2SO_4) on the acid $\text{C}_{27}\text{H}_{44}\text{O}_4$ (Diels, *Ber.* 36, 3177(1906)) indicated the addition of 4 atoms O, $[\alpha]_D^{18}$ 29° , while prolonged action showed that 7–8 atoms were combined, $[\alpha]_D^{18}$ 13° . All the ozonides m. $85\text{--}95^\circ$ and decompd. above 100° . Resinous acids and neutral substances were formed by their decompn. The amts. of O_3 added, and the manner of the addition confirm the authors' view that the secondary unsatn. is due to an opening up of a bridged ring under the influence of the O_3 . Attempts to form a thio-ozonide (Erdmann, *C. A.* 2, 3069) by heating (A) and S to $160\text{--}5^\circ$ for 8 hrs., dissolving the red mass in CS_2 , evapg., removing the free S with HPh , and purifying by repeated pptn. from HPh with alc., gave dark red, brittle solids, m. indefinitely 111° , and containing 19–21% S ($\text{C}_{27}\text{H}_{44}\text{OS}_2$ requires 20%). The fact that cholesteryl benzoate (B), with Br in CS_2 , gives a mono-Br deriv. (Obermüller, *Z. physiol. Chem.* 15, 42(1891)) was confirmed, but from the acetone mother-liquors, on keeping, were obtained flat hexagonal tablets, m. $168\text{--}9^\circ$, which had the compn. of cholesteryl benzoate dibromide, and were quant. reduced by Zn dust and HOAc to (B). Cholesteryl *m*-nitrobenzoate (C), from (A) and the acid chloride at 165° for 5 min., m. 137° to a turbid liquid which clears at 170° and gives a characteristic play of violet, green, red, and orange colors on cooling. Cholesteryl *p*-nitrobenzoate forms plates, m. 185° to a turbid liquid which decomp. 250° ; on cooling the melt the play of colors, violet, green, and red, was observed. (C) required 2 atoms Br for complete reaction in CS_2 , but the only cryst. product capable of isolation was bromocholesteryl *m*-nitrobenzoate, $\text{C}_{24}\text{H}_{40}\text{O}_4\text{NBr}$, leaves,

m. 149°. It is concluded that the negativity of the acyl nucleus hinders the reactivity of the unsatd. linking in the mol. M. HEIDELBERGER.

Polymorphism in halogen-substituted anilides. FREDERICK D. CHATTAWAY AND GEORGE R. CLEMO. Oxford. *J. Chem. Soc.* 109, 89-105 (1916); cf. *C. A.* 10, 755.—An extension of previous observations. If precautions are taken to exclude HBr and H₂O, 2,4-Br₂C₆H₃NH₂ is easily prepd. as follows: 1 mol. *p*-BrC₆H₄NHAc (or PhNHAc, using twice the given amts. of NaOAc and Br) and 1 mol. fused, powdered NaOAc are suspended in enough HOAc to make a thick paste, and 1 mol. Br in 8-10 vols. HOAc is slowly added, the mixt. being heated 5-6 hrs. on the H₂O bath until the color of Br almost disappears. On cooling and dilg. with H₂O, 2,4-Br₂C₆H₃NHAc seps.; this is immediately filtered off and hydrolyzed by boiling with aq.-alc. HCl. Yield, 90%. 2,4-ClBrC₆H₃NHAc is easily prepd. by passing 1 mol. Cl into a cooled suspension of 1 mol. each of *p*-BrC₆H₄NHAc and fused, powdered NaOAc in HOAc; it may also be prepd. from 2-ClC₆H₄NHAc, by heating in HOAc with Br in the presence of NaOAc. If a hot, satd. soln. in HOAc or alc. is rapidly cooled, the needle form seps.; this may require several days for conversion into the stable, compact form, unless the mixt. is seeded, when the change takes place very rapidly. 4,2-ClBrC₆H₃NHAc also crysts. similarly, but changes into the stable form more slowly than its isomer. The butyranilides described below were prepd. by heating (PrCO)₂O with equivalent amts. of the amines. *Butyro-2-chloro-4-bromoanilide*, needles, m. 110°, extinction 21°; *butyro-4-chloro-2-bromoanilide*, needles, m. 111.5°, extinction 31°. The phenylacetyl-anilides were prepd. from the chloride and the amine in the presence of C₆H₅N. *Phenylaceto-2-chloro-4-bromoanilide*, needles, m. 150°, extinction variable; *phenylaceto-4-chloro-2-bromoanilide*, needles, m. 148°; *phenylaceto-2,4-dibromoanilide*, needles, m. 160°. The nitrobenzoyl derivatives were prepd. from the chlorides and the amines in Et₂O in the presence of C₆H₅N or concd. Na₂CO₃ soln. *o-Nitrobenzo-2-chloro-4-bromoanilide*, needles, m. 165°, extinction, 25°; *o-nitrobenzo-4-chloro-2-bromoanilide*, plates, m. 166°, extinction, 18°; *o-nitrobenzo-2,4-dibromoanilide*, pale yellow plates, m. 178°, extinction, 24°; *o-nitrobenzo-2,4-dichloroanilide*, plates, m. 153.5°. *m-Nitrobenzo-2,4-dichloroanilide*, plates, m. 183°, straight extinction; *m-nitrobenzo-2-chloro-4-bromoanilide*, needles, m. 191°; *m-nitrobenzo-4-chloro-2-bromoanilide*, plates, m. 167.5°; *m-nitrobenzo-2,4-dibromoanilide*, needles, m. 165°, extinction variable. *p-Nitrobenzo-2,4-dichloroanilide*, seps. first from alc. as fine, almost colorless needles, slowly changing (3 weeks in 1 expt.) into compact plates; both forms m. 174°, the needles transforming below the m. p. *p-Nitrobenzo-2-chloro-4-bromoanilide*, almost colorless, felted hairs from alc., rapidly changing into pale yellow plates with straight extinction, m. 199°; *p-nitrobenzo-4-chloro-2-bromoanilide*, fine, almost colorless needles with straight extinction from alc., changing slowly into stout, pale yellow, hexagonal plates with diagonal extinction (about 3 days), both forms m. 174°; *p-nitrobenzo-2,4-dibromoanilide*, almost colorless hairs from alc., changing during 3 days to pale yellow, hexagonal plates with straight extinction; both forms m. 194°. The phthalanils were obtained by heating the amine and C₆H₄(CO)₂O to about 180° for several hrs. *Phthalo-2,4-dichloroanil*, prisms, m. 155°, straight extinction; *phthalo-2-chloro-4-bromoanil*, prisms, m. 165°, straight extinction; *phthalo-4-chloro-2-bromoanil*, prisms with straight extinction, m. 140°; *phthalo-2,4-dibromoanil*, prisms with straight extinction, m. 153.5°. The carbanilates were prepd. by slowly adding the chloroformic ester to an Et₂O soln. of the aniline containing 1 mol. C₆H₅N. *Methyl 2,4-dichlorocarbanilate*, Cl₂C₆H₃NHCO₂Me, needles, m. 70.5°; *ethyl ester*, needles, m. 89°; *methyl 2-chloro-4-bromocarbanilate*, needles, m. 76.5°, extinction 42°; *ethyl ester*, needles, m. 96°, extinction 38°; *methyl 4-chloro-2-bromocarbanilate*, needles, m. 87.5°; *ethyl ester*, needles, m. 90°; 2,4-Br₂C₆H₃NHCO₂Me; 2,4-Br₂C₆H₃NHCO₂Et, needles, m. 101°, extinction 40°; *s-2,2'*-

dichloro-4,4'-dibromodiphenylurea, needles with oblique extinction from PhNO_2 , m. 279° ; *5,4,4'-dichloro-2,2'-dibromodiphenylurea*, needles, m. 274° , extinction 40° . In prepg. the oxanilic esters from the anilines and 5 mols. $(\text{CO}_2\text{Et})_2$ at 220° for 1 hr. some of the oxanilide is formed and may be sepd. by its insoly. in boiling alc.; in the prepn. of the acids, the esters were suspended in H_2O containing a slight excess of Na_2CO_3 and treated with steam until dissolved, after which the Na salts of the acids sep. on cooling. The acids all sepd. with 1 mol. H_2O when crystd. from H_2O , but could be dehydrated by heating and obtained in anhydrous crystals from HPh or C_7H_8 . The oxanilamides were obtained from the esters and dry NH_3 in warm alc. *Ethyl 2-chloro-4-bromo-oxanilate*, needles, m. 124° ; *acid*, needles, m. 131° (decompn.); *amide*, needles, m. 243° ; *5,2,2'-dichloro-4,4'-dibromo-oxanilide*, needles, from PhNO_2 , m. 285° . *Ethyl 4-chloro-2-bromo-oxanilate*, needles, m. 121° ; *acid*, needles, m. $126-7^\circ$ (decompn.); *amide*, needles, m. 236° ; *5,4,4'-dichloro-2,2'-dibromo-oxanilide*, needles from PhNO_2 , m. 295° . *Ethyl 2,4-dibromo-oxanilate*, curved hairs, m. 130° ; *acid*, slender prisms from H_2O , needles from HPh, m. 138° with decompn. into CO_2 and $\text{Br}_2\text{C}_6\text{H}_4\text{NHCHO}$; *amide*, needles, m. 250° ; *2,4,2',4'-tetrabromo-oxanilide*, needles, m. 298° , straight extinction. At its b. p. $\text{H}_2\text{C}(\text{CO}_2\text{Et})_2$ reacts with anilines similarly to $(\text{CO}_2\text{Et})_2$, analogous products being formed (C. A. 4, 2106). These are sepd. in the same way as the $(\text{CO}_2\text{Et})_2$ derivs. and are capable of the same transformations. *2,2'-Dichloro-4,4'-dibromomalonanilide*, $\text{CH}_2(\text{CONHC}_6\text{H}_3\text{ClBr})_2$, needles with straight extinction, m. 214° ; *ethyl 2-chloro-4-bromomalonanilate*, plates with straight extinction, m. 81.5° ; *acid*, prisms, m. 165° when quickly heated, giving quant. CO_2 and $\text{ClBrC}_6\text{H}_3\text{NHAc}$; *amide*, needles, m. 149° . *4,4'-Dichloro-2,2'-dibromomalonanilide*, prisms, m. 221° , straight extinction; *ethyl 4-chloro-2-bromomalonanilate*, plates, m. 83.5° ; *acid*, prisms, m. 161° when quickly heated, giving CO_2 and the acetanilide; *amide*, needles, m. 159° . *2,4-Dibromomalonanilamide*, $\text{Br}_2\text{C}_6\text{H}_3\text{NHCOCH}_2\text{CONH}_2$, needles, m. 164° . *Benzene-sulfon-2-chloro-4-bromoanilide*, prisms with straight extinction, m. 122° ; *2-chloro-4-bromophenylchloroamide*, $\text{ClBrC}_6\text{H}_3\text{NCISO}_2\text{Ph}$, prisms, m. $111-2^\circ$ when rapidly heated; *benzenesulfon-4-chloro-2-bromoanilide*, prisms, m. 128° ; *4-chloro-2-bromophenylchloroamide*, prisms, m. 123° . *p-Toluenesulfon-2-chloro-4-bromoanilide*, plates, m. 121° ; *2-chloro-4-bromophenylchloroamide*, prisms, m. 78° ; *p-toluenesulfon-4-chloro-2-bromoanilide*, plates, m. 126.5° ; *4-chloro-2-bromophenylchloroamide*, prisms, m. 77° ; *p-toluene-sulfon-2,4-dibromoanilide*, plates, m. 134° , straight extinctions; *2,4-dibromophenylchloroamide*, prisms, m. 78° . *p-Nitrotoluene-o-sulfon-2-chloro-4-bromoanilide*, faintly yellow prisms, m. 164.5° , extinction 25° ; *2-chloro-4-bromophenylchloroamide*, prisms, m. $123-4^\circ$; *p-nitrotoluene-o-sulfon-4-chloro-2-bromoanilide*, faintly yellow prisms with 60° and 43° terminal faces, straight extinction, m. 165° ; *4-chloro-2-bromophenylchloroamide*, prisms, m. 122° ; *p-nitrotoluene-o-sulfon-2,4-dibromoanilide*, faintly yellow prisms with straight extinction, m. 173° ; *2,4-dibromophenylchloroamide*, prisms, m. $124-5^\circ$. *2-Chloro-4-bromobenzeneazo- β -naphthol*, plates with a beetle-green color by reflected light and a red color in transmitted light, m. 210° ; *4-chloro-2-bromobenzeneazo- β -naphthol*, red plates, m. 193° , give straight extinction, and are sharply pleochroic (orange-red).

M. HEIDELBERGER.

A synthesis of flavones. BROJENDRA N. GHOSH. London. *J. Chem. Soc.* 109, 105-22(1916).—Instead of using $\text{AcCHPhCO}_2\text{Et}$ in the condensation with phenols leading to the production of substituted γ -benzopyrones or flavones (C. A. 9, 2762), the nitriles RCOCHPhCN (where $\text{R} = \text{H}, \text{Me}, \text{or Ph}$), are now used, giving rise to imides from which the flavones may be produced by boiling with dil. H_2SO_4 . The condensation takes place best when a Me or an additional OH group is present; other substituents inhibit the reaction. The yields are best when 1 *m*-position to the OH is occupied; when both are occupied, or when the substituent is *o*-, no condensation

takes place. In the case of AcCHPhCN , H_2SO_4 proved to be the best condensing agent, while with HCOCHPhCN , POCl_3 and dry HCl yielded products that were easier to handle. Using BzCHPhCN , dry HCl was the only condensing agent that could be used, while BzCH_2CN reacted in the presence of H_2SO_4 . 4 g. $m\text{-C}_6\text{H}_4(\text{OH})_2$ and 5 g. AcCHPhCN were slowly treated with 15 cc. H_2SO_4 , allowed to stand overnight, and poured onto ice, giving, almost quant., *4-imino-7-hydroxy-3-phenyl-2-methyl- γ -benzopyrane sulfate* (I),

pyrane sulfate (I), yellow needles, m. to a dark red liquid 246° , gives a yellow color, with green fluorescence, in H_2SO_4 , and a violet color with alc. FeCl_3 ; in alc. soln. aq. NaOAc gives the *base* (II), brown prisms with 0.5 H_2O , m. 221° (decompn.); the *p*-quinonoid structure is assigned because the corresponding compd. from *m*-cresol (see below), in which there is a *p*-Me, is colorless; *picrate*, orange yellow needles, m. 227° ; *perchlorate*, decomp. explosively on heating; *acetyl derivative*, faintly yellow needles with 0.5 H_2O , m. 135° ; *benzoyl derivative*, needles with 0.5 H_2O , m. $178-9^\circ$; boiled with 10% aq. H_2SO_4 (I) yields NH_3 and 7-hydroxy-3-phenyl-2-methyl- γ -benzopyrone (*loc. cit.*). Similarly, using 1,2,3- $\text{C}_6\text{H}_3(\text{OH})_3$ and treating with NaOAc an alc. soln. of the yellow salt formed, there was obtained *4-imino-7,8-dihydroxy-3-phenyl-2-methyl- γ -benzopyrane*, dark brown prisms with 0.5 H_2O , sinters 125° , m. 142° (decompn.), gives a green color with alc. FeCl_3 , a brown Na salt with NaOH , and reduces $\text{AgNO}_3\text{-NH}_3$ soln. on warming; *acetyl derivative*, pale yellow needles, m. 194° ; the keto compd. is formed on boiling with dil. H_2SO_4 . $\alpha\text{-C}_{10}\text{H}_7\text{OH}$ as the phenol gave *4-imino-3-phenyl-2-methyl-1,4- α -naphthopyrane sulfate* (III), orange needles, m. 174° (decompn.); *free base*, pale brown prisms with 0.5 H_2O , m. 162° ; gives the keto compd. with dil. H_2SO_4 . $m\text{-MeC}_6\text{H}_4\text{OH}$ yielded *4-imino-3-phenyl-2,7-dimethyl- γ -benzopyrane sulfate*, yellow prisms, m. 122° (decompn.); yield, poor; *free base* (see above), needles, m. 89° , sol. in H_2SO_4 with a yellow color; hydrolysis with 10% H_2SO_4 gave *3-phenyl-2,7-dimethyl- γ -benzopyrone*, needles, m. 155° , fluoresces blue in H_2SO_4 . 20 g. POCl_3 were added to 3 g. $m\text{-C}_6\text{H}_4(\text{OH})_2$ and 4 g. HCOCHPhCN (A) and the mixt. heated to 50° to start the vigorous reaction; cooling, treating with ice, and recrystg. from HOAc containing dil. HCl gave *4-imino-7-hydroxy-3-phenyl- γ -benzopyrane hydrochloride*, yellow needles with 1 H_2O , sinters 205° , m. 215° (decompn.) (yield, almost quant.), gives a violet color with alc. FeCl_3 and a yellow-brown soln. in NaOH , evolving NH_3 on warming, gives the keto compd. on hydrolysis with H_2SO_4 ; *free base*, yellow needles with 1 H_2O , m. 226° ; *acetyl derivative*, needles, m. 186° (decompn.); *benzoyl derivative*, needles with 1 H_2O , m. 136° ; *perchlorate*, yellow needles. 4 g. each of 1,2,3- $\text{C}_6\text{H}_3(\text{OH})_3$ and (A), and 20 g. POCl_3 at $50-60^\circ$ for 0.5 hr. followed by treatment of the alc. soln. of the yellow product with NaOAc gave *4-imino-7,8-dihydroxy-3-phenyl- γ -benzopyrane*, yellow needles with 1 H_2O , sinters 208° , m. 220° , gives a green color with alc. FeCl_3 and reduces $\text{AgNO}_3\text{-NH}_3$ soln. on warming; *acetyl derivative*, needles with 1 H_2O , m. 171° ; hydrolysis with dil. H_2SO_4 gives *7,8-dihydroxy-3-phenyl- γ -benzopyrone*, pale yellow needles with 2 H_2O , m. 215° , sol. in aq. NaOH with a brown color, in H_2SO_4 with a yellow color and green fluorescence, and reduces $\text{AgNO}_3\text{-NH}_3$ soln. on warming; *acetyl derivative*, needles with 1 H_2O , m. 184° , from the imino compd., Ac_2O , and NaOAc .

4-Imino-3-phenyl-1,4- α -naphthopyrane hydrochloride, using HCl in HOAc, yellow needles with 1 H₂O, m. 135° (decompn.); *free base*, dull yellow prisms, decomp. 115–30°, fluoresces green in alc.; *3-phenyl-1,4- α -naphthopyrone*, pale yellow needles with 0.5 H₂O, m. 169–70°, sol. in H₂SO₄ with a yellow color and dark green fluorescence. Orcinol, (A), and POCl₃ gave *4-imino-7-hydroxy-3-phenyl-5-methyl- γ -benzopyrane*, yellow needles with 1 H₂O, sinters 227°, m. 235°, decomp. 241°, gives a yellow-green color with alc. FeCl₃; *7-hydroxy-3-phenyl-5-methyl- γ -benzopyrone*, pale yellow needles with 2 H₂O, sinters 218°, m. 224°, sol. in H₂SO₄ with a yellow color and dark green fluorescence. BzCHPhCN (B) is best prepd. by slowly adding, with vigorous shaking, 75 g. EtOBz to 58 g. PhCH₂CN and 11.5 g. Na in alc., letting stand for 1 hr., and boiling for 2 hrs. This method, which gave a yield of 90% when applied to the prepn. of (A) (using EtO₂CH), yielded 45% (B) (cf. Walther and Schickler, *J. prakt. Chem.* [2] 55, 308 (1897)). On passing a slow current of HCl into a well cooled soln. of (B) and *m*-C₆H₄-(OH)₂ for 5–6 hrs. and letting stand 3 days, there sepd. *4-imino-7-hydroxy-2,3-diphenyl- γ -benzopyrane hydrochloride*, pink needles with 1 H₂O, sinters 280°, m. 286°, gives a yellow-brown color with alc. FeCl₃; *free base*, yellow needles, m. 290°; *acetyl derivative*, needles with 0.5 H₂O, m. 215°; *7-hydroxy-2,3-diphenyl- γ -benzopyrone*, needles, m. 288°, boiled 4 hrs. with 33% aq. KOH it gives PhCH₂Bz, *m*-C₆H₄(OH)₂, and 2,4-(HO)₂C₆H₃CO₂H; *acetyl derivative*, leaflets with 1 H₂O, m. 222°. 1,2,3-C₆H₃(OH)₃ yielded *4-imino-7,8-dihydroxy-2,3-diphenyl- γ -benzopyrane*, yellow needles with 0.5 H₂O, m. 179–80°, gives a green color with alc. FeCl₃; *7,8-dihydroxy-2,3-diphenyl- γ -benzopyrone*, needles, m. 185°, gives a green color with alc. FeCl₃ and reduces AgNO₃-NH₃ soln. on warming. BzCH₂CN, *m*-C₆H₄(OH)₂, and H₂SO₄, after standing in the cold overnight, pouring onto ice, and decomp. the sulfate with NaOAc, gave *4-imino-7-hydroxy-2-phenyl- γ -benzopyrane*, yellow-brown prisms with 0.5 H₂O, decomp. 185–235°, gives a violet color with alc. FeCl₃ and a green fluorescence in dil. alc. soln.; decompn. with 33% aq. KOH gave AcPh, *m*-C₆H₄(OH)₂, and 2,4-(HO)₂C₆H₃CO₂H; *picrate*, orange needles, m. 238°. *4-Imino-2-phenyl-1,4- α -naphthopyrane sulfate*, prisms, decomp. 185–215°; yield, small; *free base*, pale brown prisms, decomp. 138–48°; *picrate*, orange needles, m. 274° (decompn.). *4-Imino-7,8-dihydroxy-2-phenyl- γ -benzopyrane*, brown prisms with 1 H₂O, decomp. 145–65°, gives a red color with aq. NaOH, green with alc. FeCl₃, and reduces AgNO₃-NH₃ soln. on warming. M. H.

Mercuric acetate as oxidizer in alkaloidal chemistry. J. GADAMER. Univ. Breslau. *Arch. Pharm.* 253, 274–89 (1915).—Investigations still under way have shown that Hg(OAc)₂ may be very advantageously employed as an oxidizing agent both qual. and quant. in alkaloidal chemistry, the mercurous salt formed thereby being on account of its difficult soly. easily collected and weighed. I. Action of mercuric acetate on alkaloids of the apomorphine and hydroberberine group. J. GADAMER AND FRITZ KUNTZE.—The behavior of bulbocapnine Me ether towards alc. I soln. lead G. and K. to believe that the product of oxidation was tetrahydro-bulbocapnine Me ether. However, in view of the fact that Hg(OAc)₂ detaches but 2 H atoms, the oxidation product must be regarded as a didehydrobulbocapnine Me ether (optically inactive). The reaction is expressed by the equation $C_{20}H_{19}O_4N + 2Hg(OAc)_2 = C_{20}H_{17}O_4N + 2AcOH + Hg_2(OAc)_2$. It should be noted in this connection that the quantity of pptd. Hg₂(OAc)₂ varied according as the operation was carried out at room or H₂O bath temp., in which latter case the resulting color changes indicated a more profound oxidation. Even in the cold, further oxidation could be noted. Similar treatment of *d*-canadine lead to the formation of berberine, according to the equation: $C_{20}H_{19}O_4N + 4Hg(OAc)_2 = C_{20}H_{15}O_4N.OAc + 3AcOH + 2Hg_2(OAc)_2$. Oxidation of corydaline appears to yield first didehydrocorydaline (optically inactive?) and finally tetrahydrocorydaline. II. Action on laudanotine. J. GADA-

MER AND R. KONDO.— MnO_2 and dil. H_2SO_4 convert this alkaloid, according to Pyman (*C. A.* 3, 2966), into veratrumaldehyde, 2,4,5-MeNHCH₂CH₂(MeO)₃C₆H₃CHO, and a compd., $\text{C}_{14}\text{H}_8(\text{OMe})_4$, which latter product, according to G. and K., is tetramethoxydibenzyl, $\text{C}_{14}\text{H}_{10}(\text{OMe})_4$. The above products were obtained by the action of $\text{Hg}(\text{OAc})_2$ on *dl*-laudanosine. III. Action on papaverine. J. GADAMER AND SCHULMANN.—This alkaloid is changed almost quant. into papaverinol, $\text{C}_{20}\text{H}_{21}\text{O}_5\text{N}$.

W. O. E.

The formation of pyridine and isoquinoline bases from casein. AMÉ PICRET AND TSAN QUO CHOU. *Compt. rend.* 162, 127-9 (1916); *Ber.* 49, 376-81 (1916).—The work answers the objection that alkaloids are not formed by the decompn. of proteins because proteins do not contain nuclei such as are found in alkaloid mols. P. and C. think these nuclei are formed in the plant by condensation of HCHO with primary protein decompn. products since they were able to effect such a condensation. 25 g. methylal were slowly dropped into a mixt. of 50 g. casein and 150 g. HCl (d. 1.19). After 6 hrs. heating on the steam bath, the mixt. was evapd. dry, mixed with CaO and distd. A yellow oil (9% of casein used) was obtained which contained primary, secondary and tertiary bases. After treatment with NaNO_2 , and fractional distn., the following compds. were isolated: pyridine, 2,6-dimethylpyridine, isoquinoline, 4-methylisoquinoline; a base, $\text{C}_7\text{H}_9\text{N}$, which decolorized cold KMnO_4 and formed the picrate, m. 238°, chloroaurate, m. 225°, chloromercurate, m. 235°, and chloroplatinate, m. 285°; another base, $\text{C}_{11}\text{H}_{11}\text{N}$, whose picrate m. 240°, chloroaurate, m. 195°, chloroplatinate, m. 200°, and a third base, $\text{C}_{13}\text{H}_{13}\text{N}$, whose picrate m. 185°. Curiously P. and C. were unable to detect the slightest trace of quinoline. The above expt. carried out without the addition of methylal did not form any of the above-named compds.

L. H. CHERNOFF.

The nitration of phenylpropionic acid. M. S. REITCH. *Compt. rend.* 162, 129-30 (1916).— $\text{PhC}:\text{CCO}_2\text{H}$ can be directly nitrated with HNO_3 at -20°C . without oxidation of the side chain. Substitution takes place in the *p*- and *o*- but not in the *m*-position. This does not agree with the theory that the satn. of the side chain influences orientation, for hydrocinnamic and cinnamic acids also nitrate in the *o*- and *p*-position. Furthermore, the group $\text{—C}:\text{CO}_2\text{H}$ is about 100 times more electronegative than the group $\text{—CO}_2\text{H}$, hence the rules of substitution attributed to electronegativity do not hold.

L. H. CHERNOFF.

The structure of α -amino acids. H. J. BACKER. *Chem. Weekblad* 12, 943-6 (1915).—As it is a well-known fact that the acid and basic properties of α -NH₂ acids neutralize each other but that there exists a doubt whether this neutralization is *intra*- or *intermol.*, B. tries to solve this problem by means of the elec. cond. of an α -NH₂ acid in which there is, besides NH₂ and CO₂H groups, a group of a distinctly acid character, *i. e.*, $\text{NH}(\text{CH}_2\text{CO}_2\text{H})_2$. For the neutralization of this acid (litmus), 1 mol. NaOH was required. The aq. soln. of the acid, evapd. with an excess of NH_4OH or 2 mols. KOH, deposits crystals of the mono-NH₄ and mono-K salts, which indicates that only one of the CO₂H groups is free and the other combined with the imino group. The following formulas are possible:

and

(I) has one free CO₂H group, (II) two. The basicity of an acid can be computed from the elec. cond. of its Na salt according to Ostwald (*Z. physik. Chem.* 1, 97). B. detd. the elec. cond. of $\text{NH}(\text{CH}_2\text{CO}_2\text{Na})(\text{CH}_2\text{CO}_2\text{H})$ at different dilns. and found $\mu_{100} - \mu_{25} = 11.3$. According to Ostwald and Walden ($\mu_{100} - \mu_{25}$) varies within 10 and

13 in the case of monobasic acids and in the case of dibasic acids within 18 and 25. According to this rule, it is very probable that $\text{NH}(\text{CH}_2\text{CO}_2\text{H})_2$ is monobasic, the 2nd CO_2H group being neutralized by the NH group. Formula (I) therefore is the more acceptable. It is probable that with the free acid and also with other $\alpha\text{-NH}_2$ acids the NH_4 salt formation is intramol.

J. T. FLOHN.

Action of methyl ethyl ketone on 2,3,4,6-tetranitrophenylnitramine. P. VAN ROMBURGH. *Proc. Akad. Wetenschappen* 18, 98-100(1915).—R. has shown (*Rec. trav. chim.* 8, 275(1889)) that H_2O acts on 2,3,4,6-(O_2N)₄ $\text{C}_6\text{HNNMeNO}_2$ (a) to form HNO_2 and 2,4,6,3-(O_2N)₃(HO) $\text{C}_6\text{HNNMeNO}_2$ (b), very slowly at room temp. but fairly rapidly on boiling. Later, with Sinnige, he found that when (a) is dissolved in acetone it reacts very rapidly with H_2O at room temp. This reaction has been further investigated in the present work. R. was not able to sep. and identify the reaction products other than HCN and (b), when acetone was used. The course of the reaction was more successfully followed by using MeEtCO . 11 g. (a) dissolved in 16 cc. MeEtCO to which had been added 0.8 cc. H_2O soon sepd. crystals of (b). The ketone soln. was decanted from the crystals and distd. on the water bath. A yellow liquid passed over in which were identified HCN and Ac_2 . On evacuating the distg. flask and heating further at the same temp. crystals of $\text{MeC}(\text{:O})\text{C}(\text{:NOH})\text{Me}$ formed in the receiver together with a small amt. of an unidentified liquid acid. The same reaction takes place in MeEtCO dried over CaCl_2 , but if the (a) is dried over H_2SO_4 and the MeEtCO over P_2O_5 , no reaction takes place at room temp. even after 2 days. On long-continued heating traces of HCN are produced and a faint yellow color appears in the distillate. On heating (a) alone, however, traces of nitrous vapors are formed. The products formed in moist ketone must be due to the action on the ketone of HNO_2 produced from (a) and H_2O . The action of H_2O on (a) in other solvents is being studied.

E. H.

Improved method for preparation of allyl alcohol. AGNES HOFF. *Oversigt Kgl. Danske Vidensk. Selsk. Forh.* 1915, 199-224.—The most important methods of prepn. are reviewed. The expt. of Hübner and Müller with *sym*-dichlorohydrin was reproduced after a careful sepn. of the *sym.* from the *unsym.* Both are found to yield allyl alc., the latter upon treatment with Na . Hydrolysis of allyl iodide yielded 96.8% alc. The objection to this method is the cost of allyl iodide and the diln. of the alc. produced, making sepn. difficult. The Tollens method of reducing glycerol (a) with $(\text{CO}_2\text{H})_2$ gave a yield corresponding to 25.4% of (a). By mixing (a) and HCO_2H (b) in varying proportions H. secured a much higher yield than Tollens. A mixt. of 5 mols. (a) and 3 mols. (b) showed the conversion of 36% (a) and 58.2% (b). 6 mols. (a) and 7 mols. (b) showed 44.3% (a) and 38.7% (b) converted. By mixing 5 mols. (a) with 1 mol. (b) and after each distn. adding such quantities of both as to maintain the same ratio, a yield equiv. to 54.1% of the constituents is obtained. By detg. the amt. of (a) and (b) left, proof is obtained that about 38% of both constituents has been lost. The theory is advanced that this must have been lost in the form of monoformin, although no direct proof is offered.

P. M. GLASOR.

The resolution of asymmetric quinquivalent nitrogen compounds. J. REILLY. Emmanuel College. *Proc. Cambridge Phil. Soc.* 18, 177-9(1915).—The selective action of optically active acids in effecting the resolution of externally compensated compds. is more noticeable in the case of N than of C derivs. and suggests that the non-resolution must be due to causes other than to racemization effects or to the hydrolytic dissociation of the salts. *d*-Benzylphenylallylmethylammonium *d*- α -bromocamphor- π -sulfonate was obtained in the forms *dBdA*, *dBIA*, *IBIA* and *IBdA* by combining *d*- and *l*-benzylphenylallylmethylammonium iodide with *l*- and *d*-Ag bromocamphor- π -sulfonate in dry Me_2CO . These compds. show a very slight tendency to racemize.

Upon standing for 2 months at 20°, $[\alpha]_D$ for *dBdA* decreased 1.6°. The pure compd. crystals from dry AcOEt without racemization. When recrystd. from alc. a slight fall in rotatory power is observed with a greater fall when recrystd. from CHCl_3 . The compds. are being studied further.

R. L. SIBLEY.

Equilibrium of the reduction of carbonic acid (to formic acid). G. BREIDIG AND S. R. CARTER. Karlsruhe. *Chem. Ztg.* 39, 72-3 (1915); cf. *C. A.* 8, 1584; 9, 294.—Considerable amts. of free HCOOH are obtained by the action of H and Pd black under pressure on CO_2 in the presence of H_2O ; the HCOOH is decompd. catalytically into CO_2 and H (cf. *C. A.* 6, 2912). The detn. of the equil. between these reactions between 30° and 90° gave no indication of the formation of HCHO as an intermediate product, so that it is unlikely that the formation of the latter is a stage in the assimilation of CO_2 in nature.

L. T. FAIRHALL.

Tetrabromo-*o*-phenylenediacetamide. C. LORING JACKSON AND SYDNEY A. BEGGS. *J. Am. Chem. Soc.* 38, 685-7 (1916); cf. *Am. Chem. J.* 35, 148 (1906).—4,6,1,2- $\text{C}_6\text{H}_2\text{Br}_4(\text{NH}_2)_2$, formerly obtained in only 5% yield by steam distg. the reduction product of the 2- NO_2 compd., is obtained in 78% yield (although not quite so pure) by extg. with Et_2O ; 6.5 g. treated with a slight excess of Ac_2O give 7 g. of 2-amino-4,6-dibromoacetanilide, needles from dil. alc., m. 189°. Tetrabromo-*o*-phenylenediacetamide, from the di-Br compd. in AcOH boiled 11 hrs. in sunlight with an equal wt. of Br, prisms from dil. alc., does not m. 280°. Attempts to remove the Ac groups with H_2SO_4 , NaOH or alc. NH_3 gave 2-methyltetrabromobenzacetimidazole, $\text{C}_6\text{Br}_4\text{N}(\text{Ac})\text{CMe:N}$, m. 265-6°.

CHAS. A. ROUILLER.

The essential oil of sugi (*Cryptomeria japonica*) leaves. SO UCHIDA. *J. Am. Chem. Soc.* 38, 687-99 (1916).—Steam distn. of the green leaves gives 0.70% of mobile brownish yellow oil with fresh aromatic odor, b. 155-350°, reacts violently with Br, becoming greenish and viscous, gives an intense green color and becomes very viscous when 2 drops are dissolved in 1 cc. Ac_2O and shaken with 1 drop H_2SO_4 ; it dissolves in H_2SO_4 with yellowish brown color and sepn. of a small amt. of thick reddish brown oil; it gives no characteristic color with dil. FeCl_3 , does not reduce $\text{NH}_4\text{-AgNO}_3$, contains neither N nor S, and shows $d_{15.5}^{15.5}$ 0.9217, $[\alpha]_D^{15}$ 19.29° (10% CHCl_3 soln.), n_D^{20} 1.4895, acid no. 1.0, ester value 6.56 and, after acetylation, 14.35. The following substances were isolated from the oil: *d*- α -Pinene (a); dipentene (b); an alcohol (c), $\text{C}_{10}\text{H}_{18}\text{O}$, b. 212-4°, d_{18} 0.9414, $n_D^{22.8}$ 1.4832, $[\alpha]_D$ 56.07° (8.98% CHCl_3 soln.), mol. wt. in freezing C_6H_6 162.7; cadinene (d); a sesquiterpene with 2 double bonds (e), $\text{C}_{15}\text{H}_{24}$, b. 266-8°, d_{18} 0.9335, $n_D^{22.8}$ 1.5041, $[\alpha]_D$ 15.19° (6.08% CHCl_3 soln.), mol. wt. in freezing C_6H_6 209.0; a sesquiterpene alcohol (f), $\text{C}_{15}\text{H}_{26}\text{O}$, b. 284-6°, $d_{18.5}$ 0.9623, $n_D^{22.8}$ 1.5048, $[\alpha]_D^{15}$ 16.76° (5% CHCl_3 soln.), mol. wt. in freezing C_6H_6 218.0; a new diterpene, α -cryptomerene (g), $\text{C}_{20}\text{H}_{32}$, needles from AcOEt , m. 61°, b. 345°, b_{18} 198°, $[\alpha]_D$ -34.22° (4.67% CHCl_3 soln.); a lactone $\text{C}_{10}\text{H}_{16}\text{O}_2$; caprylic acid in combination with (c); higher fatty acids free; and a blue oil, azulene. The terpenes, chiefly (a) with a little (b), form about 34% of the oil; (d) and (e), chiefly (e), 30%; (f), 4.5%; (g), 18%; (f), 12%. (c) has a powerful odor like that of camphor and peppermint and is the chief odoriferous constituent of the oil. (e) is a viscous oil with a weak hay-like odor, forms with $\text{Ac}_2\text{O-H}_2\text{SO}_4$ a yellowish green color changing to indigo and gives with HCl gas in Et_2O a dihydrochloride, brownish black oil. (g) treated in cold Et_2O with HCl gas deposits an isomer, β -cryptomerene, needles from AcOEt , m. 211-2°, mol. wt. in freezing PhOH 275-6°.

CHAS. A. ROUILLER.

Essential oil of Formosan hinoki (*Chamaecyparis obtusa*, S. et Z.) wood. SO UCHIDA. *J. Am. Chem. Soc.* 38, 699-702 (1916).—The crude oil (2.4% of the wood) on rectification with steam yielded 89.9% of mobile, lemon-yellow oil with the hinoki

wood odor; after washing with dil. soda it shows $d_{11.1} 0.8821$, $n_D^{18.5} 1.4990$, $[\alpha]_D 50.37^\circ$ (10% CHCl_3 soln.) and consists chiefly of *d*- α -pinene and cadinene, with a small amt. of oxygenated compds.; the terpenes form about 70% and the sesquiterpenes 24% of the oil. Pinene-HCl may advantageously be purified by sublimation and m. $132.5-3.5^\circ$ (cor.).

CHAS. A. ROUILLER.

Organic molecular compounds. JAMES F. NORRIS. *J. Am. Chem. Soc.* 38, 702-11 (1916); cf. *C. A.* 5, 496.—This work has been undertaken to det., if possible, the causes affecting the mutual affinity between atoms in org. mols. and the relationship between these affinities and the formation of mol. compds. The following working hypothesis has been formulated and is being tested: Every element contains a definite amt. of chem. energy which partly undergoes transformation when it combines with another element, the amt. of chem. energy in the resulting compd. being detd. by the amt. of energy transformed in its formation. The residual energy still present in the atoms makes it possible for the mol. to unite either with additional atoms or with mols. to form mol. compds. If, in the formation of the original mol., a large share of the chem. energy is transformed the resulting compd. would have little power to combine with other things; if, on the other hand, only a small amt. of the chem. energy has been lost, the compd. will still have a marked power to combine with other substances. If this residual affinity is sufficient, a compd. with another element is possible, whereas if the amt. is small a mol. compd. may be formed. In general, the change in energy taking place in the formation of mol. compds. is less than that transformed in the formation of simple compds. Thus, PCl_3 can still combine with Cl to form PCl_4 and the latter still contains available chem. energy which is no longer sufficient to react with more Cl but is sufficient to react with certain mols., many mol. compds. containing PCl_4 being known. $\text{Ph}_3\text{C}:\text{CPh}_2$ does not show the characteristics of an unsatd. compd.; it does not give a dibromide with Br, the chem. affinity of the 4 Ph groups almost completely "neutralizing" that of the 2 C atoms. They can combine with Cl, however, but in the resulting $(\text{Ph}_2\text{CCl})_2$ the Cl atoms are very labile, being easily removed by metals and reacting with H_2O at room temp. The 2 C atoms to which the Cl atoms are united do not hold the latter firmly, since they possessed but little available chem. energy, which was transformed in the formation of the $(\text{Ph}_2\text{CCl})_2$. Accordingly, but little of the chem. energy of the Cl was expended in the union and a large amt. is left available for the formation of mol. compds. and as a matter of fact a number of such mol. compds. have been prepd. According to the hypothesis compds. with an active Cl atom should be able to form mol. compds.; this has been verified with Ph_2CCl . Of compds. not containing halogens, 2 classes might be expected to form mol. compds.: (1) those containing an active element or group (verified in the case of Ph_2COH); (2) so-called unsatd. C compds. which have largely lost the power to add other atoms as the result of the accumulation of negative groups around the unsatd. C atoms (verified with $(\text{BrC}_6\text{H}_4)_2\text{C}:\text{C}(\text{C}_6\text{H}_4\text{Br})_2$). The $(\text{Ph}_2\text{CCl})_2$, m. $160-2^\circ$ (decompn.), is obtained in 90% yield from $\text{Ph}_3\text{C}:\text{CPh}_2$ in the smallest possible amt. of CHCl_3 satd. with Cl. A satd. soln. in hot CHBr_3 allowed to cool deposits crystals of the *bromoform double compound* $(\text{Ph}_2\text{CCl})_2 \cdot 2\text{CHBr}_3$. The *carbon tetrabromide compound*, from the components in CS_2 allowed to evaporate spontaneously, m. $144-7^\circ$. *Dichlorobromomethane compound*, from $(\text{Ph}_2\text{CCl})_2$ recrystd. from hot CHBrCl_2 . *Sulfuryl chloride compound*, transparent crystals rapidly efflorescing and readily decompd. by moisture. *p*- $\text{ClC}_6\text{H}_4\text{-CPhClCClPh}_2$ forms a *chloroform compound*, cubes with 1 mol. CHCl_3 , m. $58-9^\circ$, rapidly loses its CHCl_3 in the air, and a *carbon tetrachloride compound*, crystals with 2 mols. CCl_4 , m. $91-3^\circ$, quickly loses CCl_4 . [*p*- BrC_6H_4] $_2\text{C}:$, m. $251-2^\circ$, is obtained in 65% yield from 5 g. powdered $\text{Ph}_3\text{C}:\text{CPh}_2$ spread out in a thin layer, treated with 7.5 cc. Br in small portions and, after the excess of Br has evaporated, crystd. from Me_2CO , from

which it seps. as the *acetone compound*, needles with 2 mols. Me_2CO ; *methyl ethyl ketone compound*, with 1 mol. AcEt ; *diethyl ketone compound*, needles; *carbon tetrachloride compound*; *ethyl acetate compound*, loses AcOEt at the rate of 1 mg. per g. in the air at room temp.; *benzene compound*, needles. The dichloride, m. $190-2^\circ$, does not form addition products with CHCl_3 and CCl_4 . Ph_3COH seps. from hot CCl_4 on cooling in flat square crystals of the compn. $4\text{Ph}_3\text{COH} \cdot 3\text{CCl}_4$. *Acetone compound*, $2\text{Ph}_3\text{COH} \cdot \text{Me}_2\text{CO}$, prisms. Ph_3CCl gives the *carbon tetrachloride compound* $\text{Ph}_3\text{CCl} \cdot \text{CCl}_4$ and the *acetone compound* $2\text{Ph}_3\text{CCl} \cdot \text{Me}_2\text{CO}$. CHAS. A. ROUILLER.

Electrochemical experiments with organic arsenic compounds. FR. FICHTER AND EPHRAIM ELKIND. Basel. *Ber.* 49, 239-50(1916); cf. *C. A.* 9, 2543, and earlier papers.— $p\text{-H}_2\text{NC}_6\text{H}_4\text{AsO}_3\text{H}_2$ (a) is obtained in 40 g. yield by heating a mixt. of 300 g. PhNH_2 and 142 g. H_3AsO_4 in a series of small flasks, 12 hrs. at 150° instead of $170-200^\circ$ as usually recommended. Like all other aliphatic and aromatic arsonic acids studied, the pentavalent As in (a) can be reduced electrolytically only in acid soln. In 2 N HCl in a cathode chamber carefully protected from the air it is smoothly reduced to $p\text{-H}_2\text{NC}_6\text{H}_4\text{AsH}_2$ (b). With current densities of 0.08 amp./sq. cm. and cathodes of different materials the following % current yields were obtained: Cu 32.9, Pb 37, amalgamated Pb 72.0, Hg 73.1 (current density 0.18), amalgamated Zn 81.5. With Pb cathodes and current densities of 0.019, 0.038, 0.076 and 0.114 amp./sq. cm. the current yields were 24, 22.7, 35 and 54.4, resp. In aq. HCl, as the result of the decrease of HCl around the cathode, oily deposits of (b) are often formed on the more slowly working cathodes; this can be avoided by using alc. HCl. Thus, with 2.17 g. (a) in 4 cc. concd. HCl, 18 cc. alc. and 3 cc. H_2O , the current yields with different cathodes are, in the order given above, 36.2, 43.5, 78.8, 71.4, 71.9%, resp. A greater initial concn. of HCl than 2 N is not advisable on account of the lesser soly. of (b)-HCl, which seps. on the cathode as a white, powdery, cryst. layer. Addition of NaCl has the same effect; in fact, the (b)-HCl can be quant. pptd. with 5 N NaCl from the clear reduction liquid obtained at a Zn cathode. 2 N H_2SO_4 has the same disadvantage as more concd. HCl. The temp. must be carefully kept down, otherwise PhNH_2 and H_3AsO_3 are formed, the latter being further reduced to AsH_3 . $p\text{-H}_2\text{NC}_6\text{H}_4\text{AsO}$ (c) is smoothly reduced in HCl and still more easily in 2 N NaOH but even when the air is carefully excluded the reduction generally proceeds only as far as $(\text{H}_2\text{NC}_6\text{H}_4\text{As})_2$ (d), although the amt. of H utilized indicates that somewhat more than that calcd. for the above reduction is used, and at a Hg cathode in HCl is obtained a clear soln. which turns yellow only in the air, depositing (d)-HCl. F. and E. conclude that (b) is first formed and reacts with unchanged (c), giving (d). This last condensation is very rapid in alk. soln. and at Pb cathodes (d) is obtained quant. with very little more than the calcd. amt. of H. The current yields (calcd. on the basis of reduction to (d)) with various cathodes in the order given above are 29.4, 156.2, 129.8, 200, 129.0%, resp. The reason that in the reduction of (a), (c), which must be an intermediate product, cannot be isolated is that in order that (a) may be attacked a cathode potential must be set up which more than suffices to reduce (c) so that the latter cannot accumulate. PhAsO_3H_2 in aq. alc. HCl is quite smoothly reduced at all cathodes to PhAsH_2 . From 2.47 g. $o\text{-O}_2\text{NC}_6\text{H}_4\text{AsO}_3\text{H}_2$ in 2 N NaOAc electrolyzed at a cooled U-tube Pt cathode until no more H is used up is obtained 1.2 g. $(\text{H}_2\text{O}_2\text{AsC}_6\text{H}_4\text{NH})_2$, together with a little $\text{H}_2\text{NC}_6\text{H}_4\text{AsO}_3\text{H}_2$, while in HCl at a cooled Pb tube cathode is obtained a clear yellow soln. which with air gives an 82.5% yield of $(o\text{-ClH}_2\text{H}_2\text{NC}_6\text{H}_4\text{As})_2$. Partial reduction of the $p\text{-NO}_2$ acid in $(\text{NH}_4)_2\text{CO}_3\text{-NH}_4\text{OH}$ gives the hydrazo compd., oxidized by the air to the azo acid. $\text{Me}_2\text{AsO}_3\text{H}$ (e) in 2 N H_2SO_4 quickly absorbs H at a Pb cathode and at an amalgamated Zn cathode forms chiefly $(\text{Me}_2\text{As})_2$ and some Me_2AsH . In alk. solns. (e) is oxidized at the anode to H_2AsO_4 ; in such an

expt. it was found that 8.6 mols. CO_2 were formed per mol. H_2AsO_4 , instead of 2, as required by the equation $(e) + 8\text{O} = 2\text{CO}_2 + \text{H}_2\text{AsO}_4 + 2\text{H}_2\text{O}$, so some other oxidation product, also yielding CO_2 in its production, must have been formed; such a product can be none other than MeAsO_2H_2 (f) : $(e) + 4\text{O} = \text{CO}_2 + (f) + \text{H}_2\text{O}$. The current yield in the formation of (f) was 10.8% and in the total oxidation to H_2AsO_4 3.06%. (f) can also be oxidized to H_2AsO_4 ; current yield 5.15%. Below are the conductivities at 25° for V 64, 128, 256, 512 and 1024; PhAsO_2H_2 84.7, 114, 153, 200, 256; (a) 38.7, 57.9, 83.7, 116, 179; $o\text{-O}_2\text{NC}_6\text{H}_4\text{AsO}_2\text{H}_2$ 95.3, 129, 172, 225, 285.

CHAS. A. ROUILLER.

Remarks on the communication of K. Hess and Cl. Ubrig. Action of aldehydes on primary hydroxyamines. MORITZ KOHN. Vienna. *Ber.* 49, 250-1 (1916).—C. and U.'s methylene- and benzylidenediacetonealcamines (C. A. 10, 470) are probably identical with the bases obtained by K. in the same way and to which, owing to the ease with which they are converted into nitrosamines, the assigned cyclic structures (*Monatsh.* 1904, 820). C. and U.'s methylidiacetonealcamine was also previously prep'd. by K. (*Monatsh.* 1904, 137). K. believes that their comp'd. $\text{C}_{11}\text{H}_{13}\text{O}_2\text{N}_2$ is identical with his $\text{Me}_2\text{C.NH.CO.O.CHMe.CH}_3$, obtained from diacetonealcamineurethan

by loss of alc. (*Monatsh.* 1905, 942.)

CHAS. A. ROUILLER.

Obtaining liquid hydrocarbons by the action of aluminium chloride on naphthalene under pressure. FRANZ FISCHER. Kaiser Wilhelm Inst. Kohlenforschung, Mülheim-Ruhr. *Ber.* 49, 252-9 (1916).—By working under pressure with 4% of AlCl_3 , 40% of com. pure C_{10}H_8 can be converted into a mixt. of liquid hydrocarbons, the remainder forming chiefly a mixt. of tar and carbon; apparently a part of the C_{10}H_8 is hydrogenated at the expense of the rest. In evacuated sealed tubes there is no liquefaction after 3 hrs. at 280° but after 15 hrs. about 40% of the C_{10}H_8 is converted into an oil depositing no solid after 6 hrs. at 0° ; gaseous products are also formed. Similar results (except that more gas is formed) are obtained after 3 hrs. at 330° . On the other hand, 100 g. C_{10}H_8 and 4 g. AlCl_3 boiled under a reflux 3 hrs. and distd. gave 2 g. liquid up to 215° , 47 g. C_{10}H_8 satd. with oil between $215\text{--}40^\circ$, and 47 g. of a brittle tarry residue, 7 g. of which, heated to redness, gave 0.5 g. of viscous residue and 6 g. coke. From 250 g. C_{10}H_8 and 10 g. AlCl_3 heated in a 2-l. autoclave under varying conditions were obtained the following yields of oil after freezing out the solids: Heated 25 min. to a final pressure of 15 atm., 83 g.; 20 min. to 10 atm. and 330° , 92 g.; 10 min. to 5 atm., 84 g.; 8 min. to 2.5 atm., 75.8 g. With crude C_{10}H_8 , more AlCl_3 is required; with 10% AlCl_3 35% of the C_{10}H_8 can with certainty be converted into a liquid. A large quantity of such an oil obtained from a technical C_{10}H_8 ("warm presscake") was stirred some hrs. on the H_2O bath with powdered CaO and 520 g. of the filtered, brownish oil of pleasant sweetish odor gave on distn. 19.5 g. up to 150° (a) , 410 g. between 150° and 300° and 87 g. residue (b) ; the main fraction in the ice chest deposited 27% C_{10}H_8 ; the portion remaining liquid contained 91.5% C and 8.4% H, had a heat of combustion of 9932 cal., a viscosity of 1.16 at 20° , a flash point of 70° in the Pensky-Martens app. and 75° in the open cup, but could not be burned in ordinary lamps without deposition of soot. The compn. of (a) and (b) was 91.4 and 94.0% C and 8.4 and 6.2% H, resp. C. A. ROUILLER.

Conversion of α -methylnaphthalene into 1,2-di- α -naphthylethane and picene. WALTER FRIEDMANN. *Ber.* 49, 277-84 (1916).—The synthesis of picene (a) from α,α' -dinaphthostilbene (b) (Hirn, *Ber.* 32, 3341 (1899)) cannot explain its formation in lignite tar nor its occurrence in the products of the dry distn. of California petroleum residues. Lignites always contain S, which must play a considerable role in their distn.; it can be removed only with difficulty and incompletely and a part is eliminated

as H_2S in the distn. gas, indicating a reaction between it and the hydrocarbons. When 24 g. $\alpha\text{-C}_{10}\text{H}_7\text{Me}$ (c) and 3 g. S are heated in sealed tubes 24 hrs. at $300\text{--}10^\circ$ and the viscous tarry product, which contains considerable H_2S , is freed from most of the un-attacked (c) under 8 mm., the residue after several days deposits solid particles sepg. from C_6H_6 in silvery leaflets, m. $298\text{--}300^\circ$, having a compn. corresponding to $\text{C}_{10}\text{H}_8\cdot\text{CH}_2\cdot\text{S}\cdot\text{S}\cdot\text{CH}_2\cdot\text{C}_{10}\text{H}_8\cdot\text{S}$, and yielding a *picrate*, $\text{C}_{22}\text{H}_{18}\text{S}_{1.2}\text{C}_6\text{H}_5(\text{NO}_2)_2\text{OH}$, red

needles from CHCl_3 , m. 240° . Not enough was obtained to det. whether it can be converted into (b) and is therefore really an intermediate product in the formation of (b) (see below). If the (c) and S are heated 72 hrs. at 300° and the product is at once distd. *in vacuo*, after the unchanged (c) has distd. off the temp. rises rapidly to 300° , when decompn. begins, but a very viscous red-brown oil (d) passes over and at a higher temp. another distillate (e) is obtained. After some hrs. (d) becomes semi-solid and on mixing with alc. more solid is deposited while addition of light petr. ether produces a further deposit; after washing with petr. ether the solid is crystd. from C_6H_6 and alc., yielding $(\alpha\text{-C}_{10}\text{H}_7\text{CH}_2)_2$, greenish yellow tables, m. $159\text{--}60^\circ$ (Bamberger and Lotter, *Ber.* 21, 54 (1888)); *picrate*, $\text{C}_{22}\text{H}_{18.2}\text{C}_6\text{H}_5(\text{NO}_2)_2\text{OH}$, orange-yellow, m. 205° . (e) similarly treated yields a solid only partially sol. in C_6H_6 ; the sol. portion on recrystn. from alc. gives (b), m. 160° ; *picrate*, $\text{C}_{22}\text{H}_{18.3}\text{C}_6\text{H}_5(\text{NO}_2)_2\text{OH}$, orange-red to red needles, m. 210° (Elbs, *J. prakt. Chem.* 47, 56 (1893)). The part insol. in C_6H_6 gives from cumene crystals of (a), m. about 345° (Bamberger and Chattaway, *Ann.* 284, 52).

CHAS. A. ROUVILLER.

Formation of isoxazolones from aldehydes and isonitrosolevulinic acid. OTTO DIELS AND KARL SCHLEICH. Univ. Berlin. *Ber.* 49, 284-9 (1916).— $\text{AcC}(\text{:NOH})\text{-CH}_2\text{CO}_2\text{H}$ (a), m. 119° , is obtained in 27 g. yield from 100 g. $\text{AcCH}(\text{CO}_2\text{Et})\text{CH}_2\text{CO}_2\text{Et}$ and 100 g. KOH in 2 l. H_2O allowed to stand 12 hrs. with frequent shaking, treated with 40 g. KNO_3 in 1 l. H_2O , cautiously acidified with cooling and stirring with dil. H_2SO_4 , treated with 150 g. anhydrous Na_2SO_4 , extd. with AcOEt , evapd. and crystd. from Et_2O ; 13 g. in 300 cc. of 37% HCl treated with 10 g. BzH , cooled and shaken vigorously gives in 12 hrs. 10 g. (and on concn. and salting out 8 g. more) of 5-keto-4-benzylidene-3-acetyl-4,5-dihydroisoxazole, S-yellow prismatic leaflets from MeOH, m. 124° , decompd. into BzH by heating with alkalis, dil. H_2SO_4 , $(\text{CO}_2\text{H})_2$ or phthalic acid, gives with $\text{HBr}\cdot\text{AcOH}$ an intensely red soln. depositing on addition of H_2O a green ppt.; 1 g. with 0.4 g. $\text{H}_2\text{NNHCO}_2\text{Me}$ in 4 cc. warm PrOH gives 0.8 g. of the compound $\text{C}_{14}\text{H}_{14}\text{O}_4\text{N}_2$, yellow needles from HCO_2H , m. 200° (decompn.), while from 1 g. in 35 cc. MeOH with 0.5 $\text{H}_2\text{NCONHNH}_2\cdot\text{HCl}$ in $\text{AcOH}\cdot\text{MeOH}$ is obtained 0.7 g. of the semicarbazone, yellow needles from HCO_2H , m. 212° (decompn.). In the same way, from 2 g. (a) and 2 cc. furfural is obtained 1.7 g. 5-keto-4-furylidene-3-acetyl-4,5-dihydroisoxazole, deep yellow needles from AcOH or HCO_2H , m. 126° ; semicarbazone, light brown leaflets m. above 300° . 4-Anisylidene compound, in 1.5 g. yield from 2 g. (a) and 1.9 g. anisaldehyde, yellow needles from alc., m. 162° .

CHAS. A. ROUVILLER.

Partial acylation of the polyvalent alcohols and sugars. III. EMIL FISCHER AND MAX BERGMANN. Univ. Berlin. *Ber.* 49, 289-303 (1916); cf. *C. A.* 10, 900. — α -Dibenzoyldiacetonedulcitol (a), m. $185\text{--}6^\circ$, formerly obtained from α -diacetone-dulcitol (b) with BzCl and quinoline (*C. A.* 9, 1183), is also obtained in 93% yield from 1.3 g. β -diacetonedulcitol (c), 1.4 g. BzCl and 1.4 g. quinoline heated 4 hrs. at 100° and in 70% yield from the same substances kept 2 hrs. at 18° in CHCl_3 (under the latter conditions (b) gives chiefly the mono-Bz deriv.). Finally, (a) is also obtained in 95% yield from 1.3 g. (c), 1.6 g. BzCl and 1.2 g. $\text{C}_6\text{H}_5\text{N}$ after 3 hrs. at 100° and almost quant. after 5 hrs. at 18° in CHCl_3 . On the other hand, 5.2 g. (b), 6.2 g. BzCl and 4.4 g. $\text{C}_6\text{H}_5\text{N}$ heated 3 hrs. at 100° give 88% of β -dibenzoyldiacetonedulcitol (d),

sepg. from alc. in 2 forms: hair-like needles, m. $82-3^{\circ}$, and many-surfaced, hard crystals, m. $65-70^{\circ}$ and therefore apparently not homogeneous; either form can be obtained at will by seeding and both forms often sep. simultaneously; 1 g. in 5 cc. cold AcOEt treated with 5 cc. HCl (d. 1.19), dild. with 10 cc. H_2O after 3 min., heated 5 min. on the H_2O bath, treated with 10 cc. more H_2O , again heated 5 min. and allowed to stand 12 hrs. in the cold, gives 63% of α -dibenzoyldulcitol (*e*), m. 210° , whereas 5 g. (*d*) in 25 cc. cold AcOH and 25 cc. HCl (d. 1.19) kept 5 min. at 18° , dild. with 30 cc. H_2O , filtered, cooled with ice after 15 min., slowly treated with 200 cc. H_2O and kept in the ice chest 12 hrs., gives 3 g. crystals of the same compn. as (*e*) but beginning to sinter at 80° and m. $145-55^{\circ}$ and, after repeated crystn. from AcOEt-petr. ether or Me_2CO -petr. ether, m. $174-5^{\circ}$; short heating at 50° in AcOH-fuming HCl converts them into (*e*) but not quant.; the same change is effected by boiling H_2O . It is not yet certain whether the above are cases of isomerism in the narrower sense or also partially of polymorphism. α -Dianisoyldiacetonedulcitol, in 37% yield from 5.2 g. (*b*) or (*c*), 9.4 g. $MeOC_6H_4COCl$ and 8 g. quinoline heated 8 hrs. at 100° , pointed needles from CCl_4 , m. $146-7^{\circ}$. β -Compound, in 92% yield from (*b*) and 2.2 mols. each of $MeOC_6H_4COCl$ and C_6H_5N 3 hrs. at 100° , microscopic spears from alc., m. 116° . Dianisoyldulcitol, in 90% yield from the α -acetone compd. shaken 2 hrs. with AcOH containing 5% of HCl, 4-sided rectangular platelets from AcOH, sinters 192° , m. $204-5^{\circ}$. Monoanisoyldulcitol, long, felted needles, from AmOH, m. $166-7^{\circ}$, is obtained in 80% yield from 10 g. (*b*), 13.1 g. $MeOC_6H_4COCl$, 11.0 g. quinoline and 40 cc. $CHCl_3$ shaken 8-10 hrs., allowed to stand 12 hrs. in the ice chest, shaken with 120 cc. of 0.25 *N* HCl 2 hrs., extd. with 300 cc. Et_2O , washed with 200 cc. of 12% $KHCO_3$, then with H_2O , evapd., shaken in 60 cc. $CHCl_3$ with an equal vol. of 5 *N* HCl 5 hrs. and allowed to stand some hrs. in ice. Dicarboethoxysalicyldiacetonedulcitol, in 42 g. yield from 30 g. (*c*), 51 g. $MeOCOC_6H_4COCl$, 35 g. quinoline and 125 cc. $CHCl_3$ allowed to stand 2 hrs., microscopic plates or many-surfaced prisms from alc., m. $138-40^{\circ}$; 15 g. in 300 cc. alc. satd. with NH_3 at 0° and shaken 3 hrs. gives 6.5 g. crude disalicyldiacetonedulcitol (C found in samples recrystd. from ligroin, 0.4-0.5% too high), 12 g. of which, shaken 2.5 hrs. with 300 cc. AcOH containing 5% of HCl, gives 85% of disalicyldulcitol, needles, sinters about 200° , m. 219° , sol. in cold dil. NaOH, almost tasteless. Dianisoylmannitol, in 58% yield from 35 g. mannitol in 50 cc. C_6H_5N at 60° treated in the course of 45 min. with 65 g. $MeOC_6H_4COCl$ in 200 cc. $CHCl_3$, allowed to stand 12 hrs., freed from the $CHCl_3$ and about 0.5 of the C_6H_5N *in vacuo* and poured into an excess of cold dil. H_2SO_4 , thin 4-sided plates from alc., m. $175-6^{\circ}$, changed by warming with AcOEt or EtOH into felted needles or prisms, sol. in dil. alkalies with hydrolysis. Diacetylsalicylmannitol, in 53% yield from 9 g. mannitol in 100 cc. C_6H_5N treated in the course of 20 min. with 20 g. $AcOC_6H_4COCl$ and allowed to stand 2 hrs., needles from C_6H_6 , m. $135-6^{\circ}$, melts in boiling H_2O , sol. with hydrolysis in dil. alkalies and hot dil. soda, gives no marked color with alc. $FeCl_3$, has a strongly bitter taste; 30 g. allowed to stand 1 hr. at 0° in 200 cc. alc. satd. with NH_3 , then freed from NH_3 and alc. *in vacuo*, gives chiefly disalicylmannitol, microscopic, elongated, quadrangular plates from AcOEt, m. $182-4^{\circ}$, sol. with quite rapid hydrolysis in dil. alkalies, gives a strong violet-red color with alc. $FeCl_3$, has no pronounced taste; there is also formed some monosalicylmannitol, thin quadrangular platelets from H_2O , sinters 140° , m. $148-9^{\circ}$, gives with aq. $FeCl_3$ a color similar to that produced by o - $HOC_6H_4CO_2H$. Tetraacetylacetone-mannitol, in 90% yield from 4.4 g. monoacetone-mannitol allowed to stand 24 hrs. with 18 g. Ac_2O and 18 g. C_6H_5N , viscous oil, b.p. $190-200^{\circ}$ (bath temp.); with AcOH-HCl it yields a hard viscous product. (*b*) forms monoclinic prismatic crystals, $a:b:c = 0.7661:1:1.0410$, β $93^{\circ} 59'$, c (001), b (010), h (021), o (111).

CHAS. A. ROULLER.

Formation of formaldehyde and other organic substances from formic acid. I. Autoreduction of formates. K. A. HOFMANN AND K. SCHUMPELT. Berlin. *Ber.* 49, 303-17 (1916).—Having noticed that the formates of most rare earths evolve the odor of HCHO when subjected to dry distn., H. and S. heated various formates, mixed with excess of white ignited quartz sand, in a rapid current of moist CO₂, raising the temp. as quickly as possible to 450–500°. The amt. of C "assimilated," i. e., passing into org. combination, in the case of the different formates was found to increase in the following order: Ni, Fe, Mn, rare earths, Cu, Th (Na, K, uncertain), UO₃, Zn, Mg, Ca, Ba, Li. The HCHO formation is cleanest with the Pb, UO₃, Cu, Fe, Er and Th salts while with those of the other rare earths, Zn, Mn, Mg and Ca it is increasingly masked by empyreumatic substances, furfural and Me₂CO, these becoming so marked with the alkali and Ba formates that the HCHO formation becomes uncertain. The approx. amt. of formate converted into HCHO and other products using up I was detd. by titrating the distillates with I in alk. soln.; qual. tests for HCHO were made by the morphine-H₂SO₄ method; the MeOH, Me₂CO and C, which sometimes was deposited in large amts., were also detd. in the more important cases, as were the CO (in acid Cu₂Cl₂) and the H and CH₄ (C. A. 10, 303). Thus, 10 g. (HCO₂)₂Ni, dried at 90°, decomps. above 210° into Ni and almost entirely gaseous products (310 cc. CO, 804 cc. H₂ and about 50 cc. CH₄); 0.1 N I used up, 0.76 cc.; morphine test, negative. The yellow aq. soln. of the UO₃(O₂CH)₂ in direct sunlight turns dark green and evolves gas and later deposits a dark, finally black powder and on distn. yields some HCHO, a reaction to be further studied on account of its analogy with the phenomenon of assimilation by plants. HCO₂Li.H₂O decomps. above 300° with formation of thick, white vapors of empyreumatic odor; in the receiver are deposited tarry drops giving with isatin or phenanthrenequinone and H₂SO₄ a dark violet color, reducing NH₃-AgNO₃ and coloring a fir splinter moistened with HCl olive-green; indicating furfural compds. and pyruvic acid; MeOH and Me₂CO are also formed and much org. C is deposited on the walls of the distg. flask. Li glyoxalate behaves qual. so similarly that H. and S. believe that its formation precedes that of the above decompn. products and not that they are produced by HCHO, first formed, undergoing aldol-like condensation in contact with the Li₂CO₃, etc., for HCHO vapors passed over the heated residue of HCO₂Li distn. are not markedly changed. Among the gaseous products from 10 g. HCO₂Li are 1103 cc. CO, 113 cc. H₂ and 15 cc. CH₄; 0.1 N I used up, 145.5 cc., the org. C remaining in the residue (0.254 g.), calcd. as HCHO, being equiv. to 424 cc. more of I; morphine test, red-brown. This thermo-assimilation of HCO₂H (and hence of CO₂, since HCO₂H is prepd. from CO₂) through the Li salt is influenced to an extraordinary degree by the presence of other formates; thus, mixts. of 10 g. each of the Li and Ca formates yield a distillate using up 270–300 cc. I, while when distd. singly they require only 145.5 + 70.5 = 216 cc.; on the other hand, the distillate from 10 g. each of Li and Ni formates requires only 1.7 cc. I and 646 cc. CO and 3252 cc. H₂ are formed; this difference is due to the catalytic action of the metallic Ni resulting from the Ni salt, which decomps. before the Li salt. The Cu and Fe salts have a similar but less marked effect. For details as to the decompn. of the other salts, cf. the original. The apparently complicated processes can be simply referred back to the peculiar nature of the metal in the particular formate if the assumption be made that the inner displacements start from the H atoms. Under the influence of heat these atoms may work in 4 ways: (1) 2 H atoms combine to a H mol., leaving the oxalate which further decomps. into CO₂ and metal or carbonate and CO; this process, which consists first in the driving out of the H atoms, will be favored by atoms occupying a large space and by those having a strong affinity for O, for in the latter case the C atoms will have more residual affinity available for mutual combination. Na and K formates therefore yield almost only H and oxalate. The removal

of H atoms as H mols. will also be favored by such typical H catalysts as finely divided metallic Ni, such catalysts accelerating the reaction $H + H \rightleftharpoons H_2$ in both directions. The splitting off of H atoms can also be accompanied or followed by a further decompn. into CO_2 and metal when the metallic oxide is too easily reduced to form a stable oxalate. While (1) involves no "assimilation" of the HCO_2H , if the $(CO_2H)_2$ is disregarded, such an assimilation occurs (2) when a H splits off from a C atom and migrates to the next C, producing a shifting of an OM union ($M = \text{metal}$), with the formation of carbonate and HCHO (or equal vols. of H_2 and CO); this will occur most easily when the shifting of the OM union is effected by the metal itself; with the salts of polyvalent metals, the metal itself need not migrate, a shifting of one O bond being

sufficient to give a carbonate and HCHO (or $CO + H_2$), thus: $OC(H) - \overbrace{OMO} - CHO$.

Besides CO and H_2 , HCHO and some MeOH were obtained with the following salts (arranged in order of decreasing yields): Zn, UO_2 , Th, Er, Y, didymium, Ce, Mn, Fe. With the strongly basic metals, there is formed, besides HCHO, in increasing amt. as the basicity increases, Me_2CO , MeOH, furfural, empyreumatic substances and org. C, resulting from basic glyoxylates formed as intermediate products. (3) The process resulting in glyoxylates presupposes the migration of a H atom from C to an O atom doubly bound to another C and subsequent union of two C atoms:

$MOC(O)H - \overbrace{OCHOM}$. Polyvalence of the metal will also favor this process, as the

formate residues combining are thereby brought together spatially, but it will also be necessary that the metal form a strong base as basic glyoxylates only of strong bases are known. Correspondingly, it was found that Li, Ba, Ca, and Mg formates yield the products of glyoxylate distn. in increasing amts. in the order given, while Na, K and all other formates give much smaller amts.; Li, though monovalent, in all the properties of its salts greatly resembles the bivalent alk. earths. Processes (1)-(3), however, can give CO and H_2 in the ratio of 1:1 at most, whereas with Li, Mg, Ba and Th formates the ratio was found to be 4-10 times as great. This can be explained (4) by a decompn. initiated by a shifting of the H to the O of the metal and completed by the formation of H_2O and oxide or carbonate. As in the present work the distns. were carried out in CO_2 , the carbonate formation with the more strongly basic oxides favored this decompn. Arranged in order of decreasing $CO:H_2$ ratios, the metals form the series Li, Mg, Ba, rare earths, Na, K, UO_2 , Ca, Mn, Fe, Ni, Pb, Zn, Cu. In connection with the unusually high position occupied by the rare earths must be considered their marked tendency to form highly condensed oxides. (3) and (4) in the first stage are very similar in that they consist in the shifting of H from the C to O, and the formates with the highest $CO:H_2$ ratios also yield the most Me_2CO , furfural, empyreumatic substances and org. C. From the ratio $CO:H_2$ it can be approx. detd. to what extent process (4) takes place as compared with (1) and (2); in this way H. and S. calc. that in the case of the Li salt, (4) is 4.5 times as great as (1) and (2), the corresponding values for the other salts being: Mg, 2.5; Ba, 1; Th, 2; Y, Er, didymium, Ce, 1-0.5; Na, K, 1; UO_2 , Ca, 0.5; Fe, entirely according to (1) and (2). With the Zn salt, the extremely low ratio $CO:H_2 = 0.18:1$ is probably to be explained by the assumption that H_2O of crystn. or from the moist CO_2 reacts with the CO in contact with the ZnO, forming CO_2 and H. The Ni, Pb and Cu salts leave the free metals and decomp. further chiefly according to (1) and to a lesser extent according to (2).

FRANK P. UNDERHILL.

The influence of blood charcoal on peptic digestion. H. STRAUSS. *Deut. med. Wochschr.* 42, 36-8(1916).—Expts. were made with stomach juice *in vitro* and with stomach contents after giving "carbo sanguinis depuratus (Merck)" to test the adsorption of HCl and pepsin by blood charcoal. In each case it was evident that there was an adsorption of HCl, total as well as free. When the charcoal had been given to the patient the adsorption of the HCl was not so marked; the adsorption of pepsin was also less although the pepsin content of the stomach juice to which charcoal was added *in vitro* was not influenced as much as that of the HCl. It is pointed out that the stomach may secrete HCl and pepsin according to demand. Furthermore, the HCl is only loosely bound to the charcoal. S. AMBERG.

Further studies on the colloidal and physical chemistry of the cell. W. RUHLAND. *Jahrb. wiss. Botan.* 54, 391-447(1914); *Expt. Sta. Record* 33, 28.—R. has continued work previously noted (*C. A.* 7, 2951; 8, 3558), detailing results and inferences from a study of carbohydrates, alkaloids, glucosides and acids, also those from a study of the physico-chem. properties of the cell in general and of the cell as an ultra-filter in particular. The function of an ultra-filter is exercised by the plasma membrane and not by the cell wall. E. J. C.

Alterations in the forms of antagonism curves. W. J. V. OSTERHOUT. *Jahrb. wiss. Botan.* 54, 645-50(1914); *Expt. Sta. Record* 33, 31.—Previous work (*cf. C. A.* 6, 2438; 7, 394, 616) has been continued. It is shown by tables and curves how the antagonism between given percentages of NaCl and CaCl₂ may vary from time to time in the course of an expt. This is held to be due to progressive alterations in the permeability, toward each salt, of the living material employed, which in this case consisted of portions of *Laminaria saccharina*. It is thought that these 2 salts act in different ways to influence permeability. E. J. C.

Fatal temperatures for some diastases of animal or vegetable origin. E. C. TEODORESCO. *Rev. gen. botan.* 25, 599-627(1914); *Expt. Sta. Record* 33, 30.—Giving further details (*cf. C. A.* 7, 2758) of tests made with diastases heated to varying temps., T. states that when dried these support for a short period (1½ hr.) temps. above 100°, and in some cases much higher. Some suggestions as to the nature of these substances are also offered. E. J. C.

Does blood serum possess antitryptic power? SABATO VISCO. Univ. Rome. *Arch. farm. sper.* 20, 314-39(1915).—The presence of an antitryptic enzyme in the blood serum of normal individuals could not be demonstrated. Individuals affected with malignant tumors or other diseases showed no difference in this respect, either among themselves or compared with normal individuals. *Cf. C. A.* 9, 212.

A. W. DOX.

Rise in temperature produced by action of pancreatic amylase. CESARE SERONO. *Rass. clin. terap. sci. affini.* 14, 325-8(1915).—S. regards enzyme action not as a catalytic phenomenon, but as a liberation of energy through dissociation of very labile chemical groupings. 'He attempts to prove this by delicate measurements of the heat liberated in the process of enzyme action. A solution of potato starch and glycerol ext. of pancreatic amylase was used. The heat liberated is not explainable by the hydrolysis of the starch paste, but is partly due to energy set free by the enzyme. Cf. *C. A.* 9, 636.

D. I. MACHT.

Enzyme action, digestion and electrons; digestive and glucolytic enzymes and the theory of electrons. G. GALLERANI. Camerino. *Boll. soc. eustach.* 1914, No. 1/2; *Zentr. Biochem. Biophys.* 18, 192(1915).—G.'s expts. on digestion and glucolytic enzymes indicate that organic matter acts in the same manner as radioactive substances, although the action is less intense; the resemblance increases with the size, complexity and instability of the mol. The enzyme modifies the velocity of the atom electrons, *i. e.*, it increases this velocity with fixation of electrons (cleavage, but not decompn. in the case of pancreatic, gastric and salivary digestion) or diminishes it with loss of electrons (decompn. and liberation of energy as in the case of radioactive bodies and glucolysis and in general in organic decompn.) or increases and diminishes it simultaneously (aggregation and synthesis). Enzyme action is intra-atomic and its velocity may be detd. quantitatively according to the degree of fixation or loss of electrons and according to the decrease or increase of the coeff. of elec. dispersion. The specificity of a definite enzyme action is connected with the peculiar syntony and synchronism which exists between the electronic, intra-atomic motion of the agent and that of the element which is undergoing this action.

H. S. PAINÉ.

On the use of antiseptics in autolysis of animal and vegetable matter; enzymic peptolysis in germinating seeds. DOROTHY COURT. *Proc. Edinburgh Soc.* 32, 252; 34, 113-27; *Zentr. Biochem. Biophys.* 18, 190-1(1915).—In the 1st paper C. describes preliminary work with particular reference to the technic of sterilization in autolysis expts. The most appropriate antiseptic should be carefully chosen for each expt.; general directions which will cover all cases cannot be given. In the 2nd paper C. describes peptolysis expts., peptolysis in germinating barley being first studied. Witte and Roche peptones were employed and 2 distinct peptolytic enzymes were detected; 1 of these enzymes is readily extd. by H₂O, while the other is apparently an endo-enzyme which is liberated after the destruction of the cells. The 2 enzymes exhibit distinct temp. curves; the optimum temp. for each enzyme is 25-37°. Action on Roche peptone is inhibited at 50°, while the hydrolysis of Witte peptone is undisturbed at that temp. The digestion expts. were always performed with a sterile substrate. C. also performed peptolysis expts. with the fruit of *Ananas sativa*. Proteolysis and peptolysis were observed; an enzyme capable of producing cleavage of tyrosine was not observed (Roche peptone was not digested). A similar result was obtained in expts. with various fungi (*Lycoperdon*, *Hyphaloma*, *Russula*, *Boletus*, *Laccaria*, *Hydnum*, *Amanita*, and *Amentopsis*); Witte peptone was invariably attacked, while Roche peptone remained intact. The Buchner press juice of these fungi was also inactive toward Roche peptone. Both peptases were found, however, in *Agaricus campestris* and *Saccharomyces cerevisiae*. *Aspergillus* also contained both peptases; this was not true, however, of *Penicillium glaucum*, in spite of the close relationship of the 2 fungi. C. concludes from these expts. that the 2 peptases are not identical; the peptolysis is likewise quite distinct from the proteolysis observed simultaneously therewith.

H. S. PAINÉ.

Nature of opsonic substances of normal sera. HANS ZINNSEN AND EDWARD G. CARY. Stanford and Columbia Univs. *J. Exp. Med.* 19, 345-61(1914).—The albumin

fraction, or end piece, obtained by the dialysis of normal guinea-pig serum possesses definite opsonic action, which is often equal to that residing in the unfractionated alexin. It is evident, however, only if the reaction maintained throughout the expt. approximates that of the original serum. Addition of NaOH to dialyzed serum will bring back opsonic action which was not evident in the same end piece if simply rendered isotonic. The work suggests that the opsonic action of the albumin fraction is enhanced by preliminary sensitization of the bacteria with heated normal serum and by persensitization of such bacteria with the globulin fraction. While the expts. do not point to a differentiation of normal opsonin from alexin, they indicate that the so-called end piece can enter to a slight extent into nonspecific relationship with unsensitized bacteria and it is therefore active, whereas it cannot enter into a similar relation to unsensitized cells.

Chemo-serodiagnosis of cerebral hemorrhage. P. MARIE AND A. LERI. *Union pharm.*, Aug. 15, 1914; *Reperl. pharm.* 28, 18-9(1916).—The authors have made the observation that the blood serum in cases of cerebral hemorrhage is green and somewhat fluorescent, due probably to the passage into the blood of hemoglobin decompn. products of the extravasated blood. They think this diagnosis might be applicable to every case of hemorrhagic lesion from other organs.

L. H. CHERNOFF.

Analytical work. (Determination of iron in plant substances.) P. L. GILE AND J. O. CARRERO. *Porto Rico Sta. Report* 1914, 13; *Expt. Sta. Record* 33, 502.—A comparison of the KCNS colorimetric method for Fe with the permanganate method indicated that the former is preferable for the detn. of small amts. of Fe contained in most plant substances.

E. J. C.

A new procedure for removing the humus substances produced in the hydrolysis of organic substances by mineral acids. A. CLEMENTI. *Univ. Rome. Arch. farm. sper.* 20, 561-6(1915).—Colloidal Fe in aq. soln. added to the soln. resulting from the hydrolysis of org. substances by strong mineral acids, in the presence of electrolytes (e. g., Na_2SO_4) passes from the sol to the gel state and absorbs the humus substances so that they are retained by the filter. A clear, transparent liquid with a light straw-yellow color is thus obtained. This method does not entail any appreciable loss of N, and compared to the Kossel-Kutscher or the Sørensen-Jessen-Hansen method, is much quicker and easier to operate. Titration with formol after decolorizing by means of colloidal Fe gives results entirely comparable with those obtained after decolorization by either of the above-mentioned methods.

A. W. DOX.

Drugs in their relation to (chemical) properties of urine. ANON. *Gaceta farm. espan.*; *Revista sanitaria* 9, 2; through *Pharm. Post* 48, 241-3(1915).—Administration

of the following drugs causes changes in the character of urine which may lead to errors of analysis and diagnosis: (A) Drugs which change the color of urine: (1) analgen—blood-red, changed to yellow by alkali; (2) pyramidon—salmon to cherry-red; (3) sulphonal—dark red; (4) PhOH—dark green, changing to black; (5) naphthalene—dark to dark gray; (6) salol—dark green—black after long usage; (7) phenecol and its salts—reddish dark gray; (8) CHBr_3 —dark green; (9) infusions of *Folia Uvae Ursae* and *Folia Myrtilli*—dark azure; (10) thallein—yellow, changing through dark green to dark gray; (11) naphthol—olive-green (reddish yellow if very large doses are taken); (12) santonin—yellow, changed to red by alkali; (13) cascara sagrada and (14) rhubarb and senna—yellow or dark reddish yellow, changed to red by alkali. (B) Drugs which interfere with the detection of glucose: (1) Infusions of *Folia Uvae Ursae* and *Folia Myrtilli*—interfere with polarization and fermentation detns.; (2) methylene blue—interferes with the Causse-Benos test; (3) Me_2CO —ppt. with Fehling soln.; (4) anti-febrin and (5) salicylic acid in large doses—urine becomes levorotatory; (6) antipyrine in large doses—Nylander's test positive; (7) copaiba balsam and (8) chloral hydrate—urine becomes levorotatory; (9) benzoates in large doses, (10) CHBr_3 , and (11) camphor—urine becomes dextrorotatory; (12) CHCl_3 —urine reduces Fehling soln.; (13) cubebs and (14) oil of turpentine—Nylander's test positive; (15) glycerol(?); (16) *Hydrastis canadensis*, (17) morphine, and (18) quinine—positive test for alkaloids; (19) phenacetin—wine-red color with FeCl_3 ; (20) rhubarb in large doses, and (21) senna in large doses—urine reduces alk. Bi soln.; (22) salol in large doses—urine becomes levorotatory and gives tests for salicylic acid; (23) sulfonal—urine becomes levorotatory; (24) tannin in large doses—urine gives a dark blue color with FeCl_3 ; (25) urethan—forms a compd. with glucuronic acid. (C) Drugs other than alkaloids, which interfere with the detection of albumin: (1) copaiba balsam—urine will not respond to HNO_3 test; (2) methylene blue—ppt. with Esbach's reagent; (3) tincture of myrrh (after long usage)—urine becomes turbid upon heating; (4) terpin—urine gives albumin-like ppts.; (5) wrotopin—ppt. with Br water. (D) The detection of indoxyl is difficult in the urine of patients taking large doses of iodides. (E) A positive test for acetoacetic acid is given by urine of patients to whom antipyrine or compds. of salicylic acid have been given. (F) Antipyrine, CHCl_3 , and turpentine and its derivs. interfere with some tests for bile pigments. (G) Caffeine, theobromine, rhubarb, benzonaphthol and naphthyl salicylate interfere with Denigès test for xanthouric compds. (H) Certain drugs added as preservatives can mask reactions: HCHO interferes with tests for indican, pentose and acetoacetic acid; CHCl_3 interferes with tests for Me_2CO ; EtOH gives Gmelin's and Hay's reactions; Et_2O gives Gmelin's reaction.

C. O. EWING.

The Lewis and Benedict method for the estimation of blood sugar, with some observations obtained in disease. VICTOR C. MYERS AND CAMERON V. BAILEY. New York. Post Grad. Hosp. and Med. School. *J. Biol. Chem.* 24, 147-61 (1916).—To save time and manipulation the method of Lewis and Benedict (*C. A.* 9, 638) is modified as follows: 2 cc. of blood are measured, with an Ostwald pipet, into a centrifuge tube graduated to 10 cc. and the pipet is washed out with 8 cc. of H_2O . 0.2 g. of dry picric acid is now added and the mixt. thoroughly stirred with a glass rod several times during the next few minutes. The tube is then centrifugated and the supernatant liquid filtered through a 4 cm. paper. Three cc. of the filtrate are measured into a tall, narrow test-tube graduated to 3, 4, 10, 15 and 20 cc., 1 cc. of 20% Na_2CO_3 soln. is added and the tube is kept in a beaker of boiling H_2O for 15 min. The soln. is then cooled and dild. to 10, 15 or 20 cc., depending upon the depth of color. It is then compared in a Hellige colorimeter with a standard picramate soln. (0.100 g. picramic acid, 0.2 g. Na_2CO_3 in 30 cc. warm H_2O , dild. to 1000 cc.). The readings are best taken between

40 and 65, and the % of sugar is calcd. by subtracting the reading from 100 and multiplying by 0.002, 0.003, etc., according as the dilm. was to 10 cc., 15 cc., etc. If desired, a Duboscq colorimeter may be used. The standard picramate soln. should then be of such strength as to correspond in color with that developed by 0.6 mg. glucose treated as above and dild. to 10 cc. If desired, a soln. of glucose in picric acid may be used as the standard. Hyperglucemia was found in parenchymatous and in interstitial nephritis, but not in "renal" diabetes. In presence of hyperglucemia in parenchymatous nephritis there is mild glucosuria, which latter is apt to be absent in interstitial nephritis. The significance of these facts, explaining some of the phenomena of diabetes, is discussed.

I. GREENWALD.

A quantitative determination of urea. C. P. MOM. *Chem. Weekblad* 13, 72-5 (1916).—M. has found that *Urobacillus Pasteurii*, which is usually present in garden soil, can be used to great advantage for the detn. of urea. A pure culture is prepared as follows: to 50 g. of meat bouillon 10% urea is added and this inoculated with 2 to 5 g. garden soil or liquid manure and kept at 30°, care being taken that there is ready access of air to the culture as the bacterium is aerobic. Within a day 2 to 2.5% of the urea has been changed into $(\text{NH}_4)_2\text{CO}_3$, which destroys the other soil bacteria. After 2 days 5 to 6.5% has been decompd. and the weaker urea bacteria (*U. Miguelii*, *Leubii* *s. v.*) are eliminated by the action of $(\text{NH}_4)_2\text{CO}_3$; only *U. Pasteurii* survives. Within 2 days the whole process is finished and a quantity of $(\text{NH}_4)_2\text{CO}_3$ is found corresponding to 8% urea; the other 2% has volatilized during the cultivation. Fifty cc. of a 2% urea-bouillon is placed in an Erlenmeyer flask of 300 cc. capacity, inoculated with a few drops of the above culture and kept at 30° for a day. The resulting liquid contains very much urease and about 2% $(\text{NH}_4)_2\text{CO}_3$ and may be kept indefinitely for an eventual regeneration of *U. Pasteurii*. *Method of procedure:* The detn. of urea in a liquid, *e. g.*, urine, is made as follows: equal vols. urine and *U. Pasteurii* culture are mixed and the amt. of $(\text{NH}_4)_2\text{CO}_3$ present titrated (by adding excess acid, heating and titrating with alkali). The liquid is then placed in a flask, which is afterwards closed and heated in a water bath of 50°. *U. Pasteurii* is now destroyed; the enzyme, however, retains its max. activity. Within 1 to 2 hrs. a second titration is made and the amt. of urea computed through subtraction. A duplicate detn. should be made with the urine diluted to twice its vol. to make sure that all the urea has been decompd. A pure culture as old as 2 weeks is unreliable as the activity of the urease gradually decreases, so that a regeneration of the old culture in 2% urea bouillon should be made, when needed.

J. T. FLORELL.

The applicability of dry yeast to the investigation of sugar in urine. A. BOLLAND AND A. KRAUSZ. *Trencsén. Chem. Ztg.* 39, 947-8 (1915).—The authors recommend "a concd. press yeast" recently put on the market by Rudolf Adler, Vienna, because they have found it unnecessary to run check fermentations with it, and because it retains its activity for 6 months.

J. H. MOORE.

Simulation of albuminuria by intravesical injection of ovalbumin. A. CH. HOLLANDER, M. LEPEYRE AND J. GATÉ. *J. pharm. chim.* 12, 345-50 (1915).—Injection of ovalbumin into the bladder, sometimes practiced to escape military service, may be detected by adding to urine a mixt. of equal parts of HCHO and glacial AcOH which ppts. ovalbumin but does not coagulate pathological albumin. Maurel's reagent, a freshly prepd. mixt. of 33% aq. NaOH soln. 25 cc., 3% aq. CuSO_4 soln. 5 cc., glacial AcOH 70 cc., coagulates ovalbumin but does not ppt. serum albumin or serum globulin. Five cc. of the reagent placed beneath urine containing pathological albumin free from ovalbumin causes no pptn. whatever even after 1 hr.; the mixt. remains clear upon agitation. If only 0.1 g. ovalbumin per l. is present, a white ring is formed, pptg. within 1 hr. These tests are checked by means of a pptg. serum prepd. by making

4 subcutaneous injections of ovalbumin into a rabbit at intervals of 8 days. 0.5 g. ovalbumin in 5 cc. physiological NaCl soln., then 1 g. in 10 cc., and the 3rd and 4th times 1.5 g. in 15 cc. are injected. The serum, obtained 1 week afterward, whether inactivated at 56° for 0.5 hr. or not, ppts. at the rate of 1 drop per cc., a urine containing 0.1 g. ovalbumin per l. When much ovalbumin is present in urine, it tends to sep., forming a lower zone coagulable by heat. Added ovalbumin disappears completely after 48 hrs.

S. WALDBOTT.

Detection by the analysis of urine and blood of the simulation of icterus caused by the absorption of picric acid. POGNAN AND B. SAUTON. *J. pharm. chim.* 12, 350-2 (1915); cf. *C. A.* 10, 68.—Defecate urine with 0.02 part of Pb(OAc)₂, add 0.1 part of HCl and extract with Et₂O. From this soln. remove traces of Pb with H₂SO₄ and purify the crude picric acid with amyl alc. In another method of extn., add 1 cc. H₂SO₄ and 2 g. of animal black to 300 cc. of urine. After at least 1 hr., with constant stirring, filter, wash the black with H₂O, then leave filter and contents for 1 hr. in contact with 100 cc. of a warm mixt. of equal parts of EtOH and NH₄OH, filter and extract the black with the same mixt. as long as the soln. is colored. Evap. till dry, take up the residue with benzene and evap. again. A yellow soln. in H₂O indicates picric acid, which is then identified by the picramic acid test; or by a pink pptn. with SnCl₂ in HCl followed by NH₄OH, sensitive to 3.5 mg. per l.; or with methylene blue, the ppt. forming a green soln. with CHCl₃; and by fixation upon wool. Examns. of 69 icteric and 18 normal urines has shown that no resemblance exists between the reactions of picric acid and those of normal or pathologic urines. To detect picric acid in blood, render 20 cc. of blood acid with 2.5 cc. H₂SO₄ (1:2), evap. to dryness on water bath, mix the residue with an equal vol. of sand and extract with Et₂O. Evap. and apply the above tests for picric acid to the residue. The results with urine and blood show perfect agreement.

S. WALDBOTT.

A mercury ureometer of simple construction. HENRI MARTIN. *J. pharm. chim.* 12, 352-4 (1915).—The app. has no stopcocks. It consists of a narrow glass tube closed at one end, holding about 30-40 cc. and being graduated into 0.1 cc. Near the open end it is widened into a bulb. Mix 10 cc. of serum or blood with 10 cc. of 20% CCl₄CO₂H, filter and collect about 10 to 12 cc. of the nearly albumin-free clear filtrate. Put 10 cc. thereof into the app., add 1 drop of soln. of phenolphthalein and NaOH until just alk. Add Hg until the tube is almost filled, lacking 1-2 cc., fill up carefully with H₂O without mixing, and invert into a basin with Hg. By means of a doubly bent pipet introduce 5-6 cc. of NaBrO soln. and agitate, inverting the tube repeatedly, the opening being firmly closed with the finger. Finally transfer the app. into H₂O, bring the inner and outer surfaces to a level and read the vol., *n* cc. Repeat the process with 5 cc. of soln. of urea, 1 g. in 500 cc., or with 1 cc. of soln. of 1 g. in 100 cc. Observe number of cc. of N from 0.01 g. urea, *u*. The content of urea in blood is then $2n/u$ g. per l.

S. WALDBOTT.

C. BACTERIOLOGY.

ERNEST D. CLARK.

The physiological role performed by *B. bifidus* in the intestinal canal. C. A. KLING. Stockholm. *Ann. inst. Pasteur* 28, 797-806 (1914).—*B. bifidus* exerts an energetic bactericidal action upon a certain number of microorganisms such as *B. coli* com., *B. lactis aerogenes*, *B. proteus vulgaris* and *Staphylococcus aureus*. It is most probably the acid product formed by the action of the organism on sugar which causes the disappearance of the other bacteria. K. did not find thermo-labile bactericidal substances of colloidal nature analogous to those found by Eijkman and others in cultures of the bacillus and in the feces. The feces of a healthy infant have usually an acid reaction. In children fed with cow milk, on the contrary, an alk. reaction

is often observed. The sugar introduced with the food is not completely absorbed in the stomach and small intestine; that which remains is attacked in the large intestine and decomposed by *B. bifidus*. The acid reaction of the feces in health is presumably the result of this chem. process. GEO. T. CALDWELL.

A ferment contained in water producing the dehydration of glycerol. E. VOISENET. *Ann. inst. Pasteur* 28, 807-18(1914).—In waters of very diverse origins V. finds a bacillus presenting all the morphological characteristics and chem. properties of *B. amaracrylus*, which he had previously isolated from bitter wines. When it is grown in a mineral-glycerol medium glycerol is dehydrated. Hydracrylic aldehyde is first formed; in part, it is changed into acrolein. The H liberated transforms a part of the hydracrylic aldehyde into the corresponding alc. GEO. T. CALDWELL.

The tubercle bacillus and arsenic. CHARPENTIER. Paris. *Ann. inst. Pasteur* 29, 443-58(1915).—The tubercle bacillus grows well in a bouillon containing 1% of its wt. of As in the form of Na arsenate. To retard the growth of the organism double this concn. was necessary. The organism likewise grows well in the presence of atoxyl, a little less actively in the presence of Na methylarsonate and with difficulty in the presence of Na cacodylate. The organisms themselves were found to take up As from these media containing arsenical compds. Such organisms were just as virulent for guinea pigs as those grown on the usual media. In studying the action of the same compds. upon other organisms, yeast and aspergillus were found to be unaffected in the same degree as the tubercle bacillus. Injections of Na cacodylate do not modify at all the course of tuberculous infection in guinea pigs inoculated with very virulent strains although the treatment is begun at once. GEO. T. CALDWELL.

The antiputrefactive role of the bile. H. ROGER. *Ann. inst. Pasteur* 29, 545-50 (1915).—Bile modifies the intestinal flora by favoring the development of certain bacteria such as *B. coli* at the expense of certain others, notably anaerobic organisms, the most important factors in putrefaction and in toxicity. Of more importance is the fact that it diminishes the production and the action of bacterial enzymes and neutralizes the intestinal toxins. GEO. T. CALDWELL.

PITFIELD, R. L.: *Compend of Bacteriology, Including Animal Parasites*. 2nd ed. Philadelphia: Blakiston. \$1.25.

STITT, E. R.: *Practical Bacteriology, Blood-Work and Animal Parasitology*. 3rd ed. Philadelphia: Blakiston. \$1.50.

CARL L. ALSBERG.

Ricin (toxin and agglutinin) in the different species and varieties of *Ricinus*. H. AGULHON. *Ann. inst. Pasteur* 28, 819-22(1914).—Of the 21 different varieties of ricin seeds examd. all yielded the specific agglutinin. In every instance 0.001 cc. of a 50% aq. ext. agglutinated 1 cc. of rabbit corpuscles under exptl. conditions. A. concludes that the toxin and agglutinin are present in practically const. amts. for a given wt. of vegetable substance and that this ought to be considered a fixed property of the genus *Ricinus*. GEO. T. CALDWELL.

Some recent work on plant oxidases. W. R. G. ATKINS. *Sci. Progress Twentieth Cent.* 9, 112-26(1914).—A critical review is given of recent publications relating to the nature of plant oxidases, their physiological function, distribution in relation to pigmentation and role in plant pathology, and the bearing of oxidase investigations on technology. E. J. C.

The occurrence of *p*-hydroxyphenylethylamine in various mistletoes. ALBERT C. CRAWFORD AND WALTER K. WATANABE. Stanford Univ. Med. School. *J. Biol. Chem.* 24, 169-72(1916); cf. *C. A.* 8, 3704.—Indications were obtained of the presence of *p*-HOC₆H₄NH₂ in the following plants: *Phoradendron villosum* (2 specimens

parasitic on California oaks), *P. flavescens* (var. *macrophylla*) and *P. californicum*. No indication of its presence could be found in *Viscum album*, *Arceuthobium occidentale* (Jepson), *Razoumofsky cryptopoda* (Coville), *Phoradendron bolleanum*, *P. juniperinum* and one sample of *P. villosum* from Arizona, which, however, did not contain leaves.

I. GREENWALD.

The relative transpiration of white pine seedlings. G. P. BURNS. *Plant World* 18, 1-6(1915); *Expt. Sta. Record* 33, 224.—Differences in size and compn. of 3 groups of white pine seedlings under no shade, half shade, and full shade, are to be sought along the lines of photosynthesis and assimilation rather than along the line of absorption and transpiration.

E. H.

New studies on the representation of places of reduction and oxidation of the plant cell. H. SCHNEIDER. *Z. wiss. Mikr.* 31, 478-91(1914); *Zentr. Biochem. Biophys.* 18, 191(1915).—After testing the hypothesis of Unna, S. concludes that the rongalite white method is not dependable even on the assumption that especial O locales exist in the tissue. When applied to plant cells the reduction colorations prove the invalidity of the O theory and show that the blue coloration of the nucleus by rongalite white cannot depend on the oxidation of the reagent by the nucleus itself. Expts. with objects which contained no oxidizing enzymes nor free O indicated that the blue color is caused by O of external origin. Expts. with fresh material to which access of air was rigorously excluded showed that re-oxidation of the reagent is only accomplished by O of external origin and that O locales in the sense conceived by Unna do not exist (at least not in plant cells). Cf. *C. A.* 9, 1188.

H. S. PAINE.

Properties of a chromogen universally distributed among plants. J. WOLFF AND NADIA ROUCHELMANN. *Compt. rend.* 161, 399-401(1915); cf. *C. A.* 9, 3084.—In addition to their remarkable sensibility to the combined actions of laccase and HI, the chromogens have many characteristics in common. They turn dark brown under the action of laccase or of the alkali or alk. earth carbonates, and give substances of marked fluorescence when the product obtained by heating the chromogen with H_2SO_4 and resorcinol is made alk. Small amts. of quercitannin prevent the reaction of the chromogen with laccase and HI, also the presence of a chromogen prevents the oxidation of guaiacol by the laccase. W. and R. think that the brown color formed in various plants, cut fruit, dead leaves, and in macerations of green plants when acted upon by laccase indicates that one and the same substance acts as a chromogen. The work of Palladin (cf. *C. A.* 5, 300-1) is discussed.

L. W. RIGGS.

The exchange of ions between the roots of *Lupinus albus* and culture solutions containing three nutrient salts. R. H. TRUE AND H. H. BARTLETT. *Amer. J. Botany* 3, 47-57(1916).—Seedlings of *Lupinus albus* absorb more salts from mixts. of KNO_3 , $Ca(NO_3)_2$ and $Mg(NO_3)_2$ than from equally concd. solns. containing only 1 or 2 of these nitrates. The solns. of the 3 nitrates which were most favorable to absorption were much inferior to corresponding solns. in which 3 anions, $H_2PO_4^-$, NO_3^- , and SO_4^{--} were present. Under fairly comparable conditions the roots were able to absorb about half of the salts from the best solns. of the 3 nitrates and 85% from corresponding solns. with mixed anions. In solns. of KNO_3 , $Ca(NO_3)_2$ and $Mg(NO_3)_2$, as well as in solns. of KH_2PO_4 , $Ca(NO_3)_2$ and $MgSO_4$, the best absorption occurs where no single ion greatly predominates over the rest.

Equilibrium of the reduction of carbonic acid (BREDIG) 10.

F. PHYSIOLOGY.

ANDREW HUNTER.

Studies on the physiology of reproduction in the domestic fowl. XIV. The effect of feeding pituitary substance and corpus luteum substance on egg production and

growth. RAYMOND PEARL. *J. Biol. Chem.* 24, 123-35(1916); *Proc. Nat. Acad. Sci.* 2, 50-3; cf. *C. A.* 8, 3815; 9, 1932.—Feeding desiccated anterior lobe of the pituitary gland to hens during a period of declining fecundity was not followed by increased egg production. Feeding either the anterior portion of the pituitary or dried corpus luteum to growing pullets retarded their growth (corpus luteum was about twice as active as pituitary) but neither retarded nor hastened the attainment of sexual maturity as indicated by the laying of eggs. The chickens began to lay at the same age, but at a lower body wt. than the normal controls. The expts. of Clark (*C. A.* 9, 3281) are criticized on the score of insufficient study of the normal variation in egg laying in the fowls used and also because of the lack of properly selected controls.

I. GREENWALD.

Further studies in the chemical dynamics of the central nervous system. III. The nature of the process of forgetting. T. B. ROBERTSON. Univ. California. *Fol. neurobiol.* 8, 486-506(1914); *Zentr. Biochem. Biophys.* 18, 171(1915).—In analogy to the physiol.-chem. significance of sleep according to which certain products of fatigue are removed from certain regions of the brain during sleep R. explains the phenomenon of forgetting as due to the removal of certain products of the functional activity of portions of the brain. In pursuance of the development of this conception R. applies the results of the psycho-physical investigations of Ebbinghaus and others to the explanation of this phenomenon. The fading of a recollected image is held to be due to the gradual passage of a substance from the colloidal medium in which it has been deposited into the blood channel which bathes the nerve element; the recollected image is, therefore, washed away, so to speak. The formula for autocatalysis ($\log n/n_1 - n = K(t - \tau)$) may be applied to the memorizing of syllables; n is the number of syllables and t is the time consumed in learning. The process of forgetting is continuous.

H. S. PAINE.

Prothrombin and antithrombin factors in the coagulation of blood. GEORGE R. MINOT AND GEORGE P. DENNY. Johns Hopkins Univ. *Arch. Intern. Med.* 17, 101-39(1916).—The methods of Howell (*C. A.* 8, 355, 1150, 3588) were used to study the blood of 93 individuals. Considerable variations in prothrombin and antithrombin action were found in normal individuals. The variation in fibrinogen content in the blood is apparently so slight as not to be of significance in estns. of prothrombin and antithrombin. Apparent diminution in prothrombin was observed in cases of bleeding, jaundice and hemophilia and an increase in leucemia and thrombosis. Increase in antithrombin content was observed in only 3 cases, 1 each of acute splenomyelogenous leucemia, aleucemic leucemia and congenital hemophilia, all of whom bled. A diminished antithrombin content was found in cases of severe typhoid fever, certain leucemias and anemias and thrombosis. Cases of spontaneous bleeding may have normal coagulation factors.

H. GIDEON WELLS.

Further results with the coagulation reaction in lues. M. BRANDT. *Deut. med. Wochschr.* 41, 915-7(1915).—There exists a far-reaching agreement between the results of the Wassermann reaction and the coagulation reaction of Hirschfeld and Klinger. Over 500 cases were examd. In some instances the coagulation reaction seemed more valuable than the Wassermann. Relatively frequently the sera proved coagulating by themselves, but this was most probably due to faulty methods of taking the blood or sending it in.

S. AMBERG.

The action of hypophysis extract in cases of hyperthyroidism. J. PAL. *Deut. med. Wochschr.* 41, 1537-9(1915).—Pituitrin, pituglandol, etc., administered subcutaneously, have no influence on normal thyroid glands nor on certain forms of goiter.

They do act on hypersecreting glands. The thyreotoxic symptoms decrease, while frequently at the same time the size of the goiter increases. It seems that the secretion into the follicles is independent of the formation of the toxin. S. AMBERG.

The permanganate (or urochromogen) reaction and the diazo reaction. S. E. C. BOSCH. *Deut. med. Wochschr.* 42, 17-8(1916).—The examn. of about 1000 urines showed that the diazo reaction was never obtained without the permanganate reaction, but that among severely tuberculous patients the latter was found more than twice as frequently as the diazo reaction. In these cases both reactions are bad prognostically. S. AMBERG.

The fat content of the human spleen. A. SCHMINCKE. *Münch. med. Wochschr.* 62, 941-4(1915).—Spleen and blood of patients having died of various diseases were examd. 6 to 14 hrs. after death. 25-100 g. spleen were treated with CaSO_4 , according to Windaus, and extd. 5-6 days with ether, yielding the total fat. This was divided in 2 parts, in one of which the phosphatides were detd.; in the other the cholesterol was detd. as cholesterol digitonin. The rest was the "Begleitsubstanz" of Wacker. In the analysis of the blood the method of Wacker and Hueck was employed. The various fat constituents were identified as above. In one case of pneumonia blood was obtained 2 hrs. before and 6 hrs. after death. The values obtained for total fat as well as for its constituents were identical. The morphological examn. of the spleens with various fat stains did not permit any conclusion as to the amt. of fat detd. by chem. analysis. The total fat content of 27 spleens varied between 0.71 and 1.51%. It was not possible to establish any relationship between the fat content and age, body weight and disease. The analysis of the total fat for cholesterol, "Begleitsubstanz," lecithin and neutral fat showed considerable variations in these substances. The total fat content of the blood expressed in % is lower than that of the spleen. There is no parallelism between the total fat content of blood and spleen, nor between their partial lipoids. S. AMBERG.

Investigations concerning the antitoxin content in the serum of tetanus patients. H. WINTZ. *Münch. med. Wochschr.* 62, 1564-6(1915).—Tested on mice the serum of tetanus patients contains tetanus antitoxin. The antitoxin content is highest about the time of beginning re-convalescence. Injection of serum in mice before administration of toxin can protect; injection after the administration of toxin did not cure. The amt. of antitoxin in the serum of the patients is too small to permit of its therapeutic use. S. AMBERG.

Relations of diabetes insipidus to the hypophysis and its treatment with hypophysis extract. J. HOPPE-SEYLER. *Münch. med. Wochschr.* 62, 1633-5(1915).—When a case of diabetes insipidus was treated with subcutaneous injections of pituitrin the urine secretion diminished while its concn. rose. Treatment with atropine was followed by a diminished urine secretion but without change in its concn. Feeding of fresh glands had no effect. S. AMBERG.

The technic and clinical applicability of the Abderhalden reaction. E. BUNZER AND F. BLOCH. *Münch. med. Wochschr.* 63, 6-10(1916).—Special attention is called to some of the 16 cases examd. In one case with tuberculosis of the lungs the patient's serum reacted with lung, liver and testicle. It was found then that there had been a tuberculous affection of the testicles. The serum of a case of cirrhosis of the liver reacted only with spleen. Another with cirrhosis of the palpable spleen reacted strongly with spleen and liver, less with kidney and lung. The urine did not contain albumin but on autopsy some changes were found in the kidney. A case of chronic lymphatic leucocythemia reacted with spleen and kidney. The value and significance of the Abderhalden reaction are not decided as yet. S. AMBERG.

The typhoidin quotient. Quantitative studies of the cutaneous test of typhoid immunity. EUGENE S. KILGORE. Univ. Calif. *Arch. Intern. Med.* 17, 24-31(1916); cf. *C. A.* 8, 1986; 9, 333.—The typhoidin reaction was applied by making 2 abrasions (without drawing blood) by rotating a chisel having a 2.5 mm. blade. Typhoidin was applied to one spot and the control soln. to the other. The typhoidin consisted of the dried, killed culture of typhoid bacilli in glycerol-bouillon and the control was dried glycerol-bouillon. The typhoidin quotient is the ratio, after 24 hrs., of the diam. of the typhoidin spot to that of the control. While in individual cases the test has a high probable error and is not conclusive, it would seem to be very useful in statistical studies. Values of the quotient considerably greater, or less, than 1.50 indicate immunity and non-immunity, respectively. I. GREENWALD.

The splenic pathology of pernicious anemia and allied conditions. A duodenal method of estimating hemolysis. J. P. SCHNEIDER. Univ. Minn. *Arch. Intern. Med.* 17, 32-41(1916).—Examn. of the duodenal contents of fasting individuals showed a marked increase in the content of bilirubin, urobilin and urobilinogen in cases of pernicious anemia. This is not the case in chronic intestinal hemorrhage. I. G.

Blood urea determinations in 211 cases. HAROLD SCHWARTZ AND CAROLINE MCGILL. Butte, Mont. *Arch. Intern. Med.* 17, 42-77(1916).—Marshall's method was used (cf. *C. A.* 7, 2048, 3979). The urea content of the blood of normal fasting adults varied from 0.108 to 0.252 g. per l. Larger amts. were found not only in nephritis but also in a number of other conditions, particularly when advanced. In lobar pneumonia a high urea content indicates an unfavorable prognosis. The urea content of transudates is approx. that of the blood. I. GREENWALD.

Non-parasitic chyluria. K. I. SANES AND MAX KAHN. Pittsburgh. *Arch. Intern. Med.* 17, 181-92(1916).—Description of a case of chyluria, with results of examn. of urine and blood. The condition was apparently due to a functional disturbance of the kidney cells. I. GREENWALD.

A study of the lipin content of a case of Gaucher's disease in an infant. H. R. WAHL AND M. L. RICHARDSON. Western Reserve Univ. *Arch. Intern. Med.* 17, 238-59(1916).—Description of the changes in the tissues in a case of Gaucher's disease. "In Gaucher's disease the liver and the spleen show not only a marked increase in the lipin content, but also a serious alteration in normal relations of the lipins to each other. The fixed fats are greatly reduced, while the lipoids, such as lecithin and cholesterol, are greatly increased. In our case a lecithin-like body predominated, but a cholesterol compd. may prevail in other cases." I. GREENWALD.

The control of experimental cretinism. H. R. BASINGER. Univ. Chicago. *Arch. Intern. Med.* 17, 260-78(1916).—The expts. were performed on rabbits. From each litter 1 or 2 were kept as controls; the others were thyroidectomized at the age of 2 or 3 weeks. After being kept with the mother until 6 weeks old, they were fed a uniform diet of oats, carrots, alfalfa hay and H₂O. The usual retardation of growth was observed in the thyroidectomized rabbits ("cretins"). The symptoms could be greatly relieved and growth stimulated to almost the normal degree by careful feeding with dried thyroid; discontinuing the feeding led to a return of the symptoms of cretinism. Koch's thyroid metaprotein (*C. A.* 7, 1517) is more active than dried thyroid but is also more toxic. Kendall's ext. B (*C. A.* 9, 1625, 2673) had no effect upon the symptoms of cretinism and was also non-toxic. Transfusion of serum from rabbits that had been fed on thyroid stimulated growth and relieved the other symptoms of cretinism, but not to so great a degree as did thyroid feeding. Serum from normal rabbits was ineffective. "Cretins are more susceptible than the normal animals to the toxic action of thyroid (thyroid feeding). Cretin rabbits, despite their retarded rate of

growth, continue to grow for a considerably longer time (4 to 6 weeks) than the controls of the same litter." I. GREENWALD.

The permanganate reduction index of cerebrospinal fluid. W. O. HOFFMAN AND A. B. SCHWARTZ. Chicago. *Arch. Intern. Med.* 17, 293-302(1916).—The permanganate reduction index of Mayerhofer (*Wiener klin. Wochschr.* 23, 651(1910)) is the number of cc. of 0.1 N KMnO_4 reduced by 1 cc. of cerebrospinal fluid. (H. and S. do not give details.) All normal fluids or fluids obtained from patients without active inflammation of brain or meninges give low indices (below 2). In early stages of inflammation, serous meningitis, encephalitis, etc., the index is between 2 and 2.5. Higher indices, if constant, almost invariably indicate active inflammatory processes, particularly tuberculous meningitis and acute poliomyelitis. The test is considered to have distinct value. I. GREENWALD.

Studies in typhoid immunization. VI. Treatment of typhoid fever by intravenous injections of polyvalent sensitized typhoid vaccine sediment. FREDERICK P. GAY AND HENRY T. CHICKERING. *Arch. Intern. Med.* 17, 303-28(1916).—The results of the treatment of typhoid fever patient by means of injections of a sensitized polyvalent killed typhoid sediment indicate that the treatment may have considerable value. Cf. C. A. 8, 1986; 9, 333. I. GREENWALD.

The interpretation of a positive nitrogen balance in nephritis. HERMAN O. MOSENTHAL AND ANNABELLA E. RICHARDS. Johns Hopkins Hosp. *Arch. Intern. Med.* 17, 329-40(1916).—"A marked positive balance of N in cases of nephritis on a mixed diet is not necessarily followed by a corresponding increase in the non-protein N of the blood. Until these phenomena are elucidated, discretion must be exercised in interpreting a normal figure for non-protein N of the blood as indicating that no N retention has taken place, and in considering a positive N balance as an absolute indication of the inability of the kidney to excrete this substance." I. GREENWALD.

Morphology and function of the ovary under normal and pathological conditions. B. ASCHNER. Halle. *Arch. Gyn.* 102, 446(1915); *Zentr. Biochem. Biophys.* 18, 165 (1915).—A. attempted to study modifications of ovarian function by means of the Abderhalden reaction (decompn. of ovary by serum). Decompn. of ovary or corpus luteum was observed in certain instances of pregnancy toxicosis, but not in normal pregnancy; the result was negative in menstruating women and positive in ovarian hemorrhages. Decompn. of ovary and spleen was observed in chlorosis. Administration of preps. of these organs would appear to be of therapeutic value. H. S. PAINE.

Serum antianaphylaxis in man; measles antianaphylaxis. G. BESSAU. Breslau. *Jahrb. Kinderheilk.* 81, 183-210, 293-312(1915); *Zentr. Biochem. Biophys.* 18, 197 (1915).—B. reports studies of cases of serum disease. Antianaphylaxis, which was especially pronounced in the more severe forms, was detected by intracutaneous tests. Isolated exanthem efflorescence is not considered to be the expression of a local antigen-antibody reaction. Antianaphylaxis is non-specific in serum disease. B. does not regard antianaphylaxis in the case of serum anaphylaxis as an absorption antianaphylaxis in the sense employed by Friedberger. Both tuberculin hypersensitiveness and serum hypersensitiveness are diminished in measles; peptone hypersensitiveness is also diminished during the course of measles. Toxin and endotoxin reactions are not influenced by measles. B. regards the condition of non-sensitiveness in measles as antianaphylaxis. H. S. PAINE.

Diabetes insipidus with the disease aspect of insufficiency of several glands with internal secretion. NOEL ORLANDI. Milan. *L'osped. maggiore* 1914, No. 9; *Zentr. Biochem. Biophys.* 18, 161(1915).—O. studied a case of diabetes insipidus with polyuria,

physical and mental deficiency, obesity and increased tolerance for carbohydrates. This disease aspect is associated with insufficient functional activity of certain glands with internal secretion, especially the hypophysis, ovaries, etc. The marked amelioration which followed hypophysin administration supports the theory of hypophysis insufficiency in diabetes insipidus. Especially noteworthy was the positive outcome of the Abderhalden reaction, *i. e.*, the detection of enzymes which decompd. hypophysis tissue.

H. S. PAINE.

Influence of ovarian transplantation; origin of osteomalacia. ANON. Halle. *Z. Geb.* 77, 49-81(1915); *Zentr. Biochem. Biophys.* 18, 165-6(1915).—A considerable decrease in Ca content of the bones was observed after transplantation of the ovaries of animals (rabbits) of the same litter. Transplantation of the ovaries of offspring to the mother animal caused a moderate decrease, while transplantation of fetal ovaries to the mother animal caused no detectable decrease in Ca content even after 3 mos. No distinct change in Ca content was observed after castration. The Ca content of the blood was not altered by transplantation, castration or injection of ovarian and corpus luteum ext.; neither did the blood of pregnant animals show any variation in Ca content. Injection of ovarian substance caused pronounced hyperemia of the genitals (and even manifestations resembling rut). Internal secretory disturbance of function with hyperfunction of the generative gland probably plays a part in the etiology of osteomalacia.

H. S. PAINE.

Immunity reactions of an inagglutinable strain of *Bacillus typhosus*. JAMES MCINTOSH AND JAMES M. McQUEEN. Aberdeen Univ. *J. Hyg.* 13, 409-21(1914); *Zentr. Biochem. Biophys.* 18, 197-8.—Injection of an inagglutinable strain of *B. typhosus* into rabbits caused the formation of a sp. agglutinin for typhoid bacilli and also the production of group agglutinins for other members of the typhoid-coli group. The inagglutinable strain absorbed the agglutinin; the antigenic properties of the inagglutinable bacillus were not impaired. Chem. agglutinants, especially acids, had an agglutinating action on all typhoid strains, but this agglutination was somewhat retarded in the case of inagglutinable bacilli; the latter owe their property of non-agglutination to some change of a physical nature and not to a loss of receptors. The inagglutinable typhoid bacilli are probably more resistant to physico-chem. influence than are normal typhoid bacilli.

H. S. PAINE.

Prophylaxis of serum disease, especially by antianaphylactic protective inoculations. R. ORTO AND P. A. HOFFER. Berlin. *Z. Hyg.* 80, 1-29(1915); *Zentr. Biochem. Biophys.* 18, 196(1915).—O. and H. detd. the minimal serum doses and min. time required for antianaphylactic protection in the case of anaphylactic guinea pigs. Serum doses of 0.5-1.0 cc., which in themselves only produce slight anaphylactic phenomena in highly hypersensitive guinea pigs, gave sufficient protection against subcutaneous injection of a fatal dose. Subcutaneous injection of 0.5-1.0 cc. serum is recommended for production of antianaphylactic protection in man. O. and H. report results of only practical interest regarding epinephrine and purified serum.

H. S. PAINE.

Application of the dialysis method to the detection of pregnancy; experiments on the recognition of tuberculosis and other infectious diseases in domestic animals. W. PFLEGER, R. STANDFUSS AND E. ROEPKE. *Centr. Bakt. Parasitenk., Orig.* 75, 525-92(1915); *Zentr. Biochem. Biophys.* 18, 189(1915).—Enzymes which decompose placenta as well as tuberculous tissue were detected in the serum of pregnant and tuberculous animals; these enzymes are not regarded as specific. The serum of pregnant animals decompd. tuberculous tissue and the inverse relation was likewise true; other tissues, such as the liver and placenta of other animals, were also attacked. The serum of non-pregnant and non-tuberculous animals frequently gave the Abderhalden reaction with

placental and other tissues. Certain tissues are unusually subject to attack by the serum of pregnant, sick and even normal animals. A critical review of the literature is given.

H. S. PAINE.

Variations of urea content in the cerebrospinal liquid, blood and urine of patients affected with certain epidemic diseases. O. FERRIER. *J. pharm. chim.* 12, 314-8 (1915).—Urea was detd. by the method of Grimbert and by means of Yvon's Hg ureometer. In *tetanus*, an amt. of 1.2 g. of urea per l. of cerebrospinal liquid is liable to be fatal; less than 1 g. in decreasing tendency is very favorable. In *meningitis*, a urea content greater than 0.1 g. per l. must be considered abnormal. In *tuberculous meningitis*, the urea content is very little increased and may even remain normal to the end. In *cerebrospinal meningitis* due to meningococci or paracocci, when specific sera have been injected at once, the max. urea content detd. in 238 tappings is not high (about 0.5 g.) and becomes normal after the 3rd injection. In serious cases of meningitis treated tardily, or having microbic complications, the initial urea content is very high; when it exceeds 0.8 g., the case will probably be fatal. Urea in the blood of 30 typho-vaccinated patients varied between 0.72 and 1.48 g. per l. In healthy persons, the ratio cerebrospinal urea : urea of blood detd. at nearly the same time, is nearly always 1:4. In cerebrospinal meningitis it increases to $\frac{1}{4}$, $\frac{1}{2}$, and in grave uremia to 1 and more. Above 1, the case is quickly fatal. Elimination of urea through urine is considerable in tetanic and meningitic patients during recovery: 25, 28, 35 g. urea per l. and 1.5 to 2 l. in 24 hrs. Still, the ratio, urea in blood:urea in urine, is not reliable diagnostically, owing to its variation in urine within one day and on successive days.

S. WALDBOTT.

Sugar content of the blood in physiological and pathological conditions. II. Blood sugar under pathological conditions. O. SCHUMM AND C. HEGLER. Hamburg-Eppendorf. *Mitt. Hamburg. Staatskrankenanstalt.* 13, 187-200(1913); cf. *C. A.* 7, 639.—The reduction power of the blood was detd., before and after fermentation, in normal and pathological cases with fasting individuals and after feeding 100 g. sugar. The method of Michaelis-Rona-Bang was used. Expts. with the method of Bertrand showed that it was not suitable for the detn. of sugar in blood. The feeding of 100 g. sugar increased the blood sugar content in normal cases from 8 to 34%. The values for the pathological cases showed considerable variation from the normal.

III. O. SCHUMM. *Z. physiol. Chem.* 96, 204-35(1915).—The residual reduction of the blood is not, as Griesbach and Strassner (*C. A.* 8, 1133) supposed, simply a product of the old Bang method. Samples of fermented blood give reducing substances by the method of Lehmann-Maquenne. A part of this residual reduction comes from the yeast. The samples of fresh and well washed yeast used invariably yielded H_2O -sol. reducing substances upon digestion with H_2O . It is not known to what extent the reducing substances of the blood are destroyed by yeast fermentation. Since part of the residual reduction of the blood comes from the yeast used, all the older figures must be considered too high, and, for the same reason, the content of fermentable sugar is too low. The further observations of Griesbach and Strassner, that the reduction and polarization values were practically detd. by the amt. of grape sugar present, needs confirmation by the examn. of a large number of normal cases. Bang's micro-method, with normal human blood, yields high values. The titration must be carried out in CO_2 . With values of 0.05-0.1 mg. of reduction, values can only be detd. as the average of several detns. The method of Lehmann-Maquenne is very suitable for the study of human blood. With small amts. of blood sugar it gives somewhat lower values than the old Bang method.

C. J. WEST.

Agglutination in pertussis, its characteristics and its comparative value in clinical diagnosis, and in determination of genus and species. OLGA R. POVITZKY AND EDWARD

WORTH. N. Y. City Health Dept. *Arch. Intern. Med.* 17, 279-92(1916).—Strongly agglutinating pertussis sera were obtained by inoculating rabbits with living or dead cultures of *B. pertussis*, preferably the former. The agglutination is quite specific, particularly in sera of high titer. Apparently all the strains of *B. pertussis* tested belong to one group. About 33% of human, non-pertussis sera show agglutination in dilutions of 1:40, and 17% in dilns. as high as 1:100. A dilution of not less than 1:200 is necessary for a practically positive diagnosis of pertussis by an agglutination test.

I. GREENWALD.

H. PHARMACOLOGY.

ALFRED N. RICHARDS.

Therapeutic effect of colloidal gold. FRANCESCHINI. *Gazz. ospedali clin.* 36, 1293-4(1915).—A review of a paper by Basquet (*La presse med.* Sept., 1915). Most of the preps. are made by mechanical pulverization of Au_2O_3 . These suspensions have a blue color and exhibit the Brownian movement. Three concns. are used: 0.0025, 0.001 and 0.01 g. per cc. A violet sol obtained by Bredig's method was injected intravenously into rabbits and dogs. The following results were obtained: *Toxicity*: In a 70 kg. subject the toxic dose was 3.6×10^{-4} g. per kg. *Thermal action*: Sharp increase in temp. followed by abundant sweating, and final decrease in temp. *Action of coagulating power of the blood*: None. *Action on the secretions*: Injections of 0.0001-0.0005 g. per kg. did not noticeably modify diuresis. A dose of 0.01 g. per kg. diminished the renal secretion of the rabbit, and on that day the urine was albuminous. The results are negative in the case of salivary, pancreatic and biliary secretions. *Cardio-vascular action*: Injection of 0.0002-0.0005 g. per kg. produced a rise in max. pressure and a fall in min. pressure lasting about 5 min. After 24 hrs. these pressure effects were reversed and there was a consequent reduction in differential pressure. Colloidal Au does not have, like many other metal sols, a bactericidal action *in vitro*.

H. W. BANKS, 3RD.

History of structural chemistry and its significance for scientific pharmacology. A "pseudo-historical" study. ANON. *Chem. Ztg.* 40, 101(1916). J. H. MOORE.

Arsenic therapy in anemia. EDWIN REINHARDT. Hamburg-Eppendorf. *Mitt. Hamburg. Staatskrankenanstalt.* 14, 51-71(1913).—A review of the literature of As therapy and a report of some expts. with elarson. C. J. WEST.

The danger of poisoning from projectiles. L. LEWIN. *Apoth. Ztg.* 30, 19-20 (1916).—A discussion of the chem. and biological factors likely to operate in the event that projectiles or their fragments are permitted to remain in the body. W. O. E.

Some clinical, physiologic and chemical observations on ptomaine poisoning from "creamed" codfish. M. A. BLANKENHORN, G. E. HARMON AND PAUL J. HANZLIK. Cleveland, O. *Arch. Intern. Med.* 17, 140-52(1916).—A description of general ptomaine poisoning in Lakeside Hosp. The symptoms observed are described. The material responsible was "creamed" codfish. Upon examn. there were found *B. coli communior*, other saprophytes and some staphylococci. The disturbance was not to be attributed to infection but to the presence in the fish of products of putrefaction. These products were capable of producing marked fall in blood-pressure and stimulation of surviving uterine and intestinal tissue. Chem. reactions indicated the presence of a substance resembling diamines such as putrescine, cadaverine and histamine.

I. GREENWALD.

I. ZOÖLOGY.

R. A. GORTNER.

Changes in the weight and composition of fasting lobsters, *SCIROGUS MONGOLIS*. J. Biol. Chem. 24, 137-46(1916).—The comparatively slight loss of wt. exhibited by

fasting lobsters is due to imbibition of H_2O , masking an actual loss of dry substance. Detailed detns. of various tissue components are given. I. GREENWALD.

Changes in the yolk granules of amphibia in intracellular digestion. C. SAINT-HILAIRE. *Zool. Jahrb.* 34, 107-221(1914); *Zentr. Biochem. Biophys.* 18, 148(1915).—The yolk elements are to be regarded as distinct morphological units which exist in the protoplasm as separate living entities; they are not to be considered as merely reserve material. Although the yolk elements show a general agreement in chem. constitution they exhibit certain structural and chem. variations in even closely related animals. Certain const. mutual relations (especially with respect to interchange of material) exist between the protoplasm and yolk granules. The action upon the yolk granules of an enzyme contained in the protoplasm is of especial importance; the granules are gradually decompd. and their decompn. products (especially fat) are incorporated in the protoplasm. H. S. PAINE.

12. FOODS.

W. D. BIGELOW AND F. F. FITZGERALD.

Examination of honey. THURE SUNDBERG. *Kungl. Landbruks-Akad. Handl. Tidskr.* 54, 696-709(1915).—Analytical data of 44 samples and some suggestions on methods. A. R. ROSE.

The analysis of maple products. VI. A volumetric subacetate test for purity of maple syrup. J. F. SNELL, N. C. MACFARLANE AND G. J. VAN ZOEREN. *J. Ind. Eng. Chem.* 8, 241-3(1916); cf. *C. A.* 10, 940.—The volumetric $Pb_2O(C_2H_3O_2)_2$ test consists in diluting the sirup to 10 times its original vol., and titrating with $Pb_2O(C_2H_3O_2)_2$ soln. The end point is obtained by measurements of elec. resistance. Apparently this method will prove the most useful single test for purity of maple products yet proposed. H. S. BAILEY.

Influence of rainfall on composition of tomatoes. W. D. BIGELOW. *Am. Food J.* 11, 58-9(1916).—During seasons of excessive rainfall, many canners find that tomatoes are unusually "sloppy," as indicated by the amt. of water that seeps on the peeling table and in the can. Some canners have the impression that food officials judge the presence or absence of added water by such appearances or by the insol. screened solids, while, in fact, a chem. detn. of sol. solids in the liquor is the basis of judgment. If marked variation in sol. solids corresponded with variation in rainfall added water could not be detd. in this way. During the seasons of 1914 and 1915, a study of the problem was made at the lab. of the National Canners' Assoc. Raw tomatoes, of known variety and obtained from different sources, were examd. as they ripened throughout the season. B. reports that compn. varies through rather wide limits with variation of cultural environment. There was also considerable variation between successive pickings of tomatoes from the same plants, a general tendency toward decrease in sol. solids with advance of season being indicated. There was no significant correlation between sol. solids and excessive rainfall. A table is included giving per cent of sol. solids, rainfall in inches, and the corresponding period of the season. G. A. MENGE.

Determination of caffeine in tea by sublimation. E. PHILIPPE. *Mitt. lebensm. Hyg.* 6, 177-91, 233-47(1915).—P. gives data to prove that caffeine can be sublimed quant. in his app. (*C. A.* 8, 1073) with a max. loss of 1%, and that all the caffeine can be extd. from 3 g. of tea, which has been treated with 10 cc. NH_4OH in a separatory funnel, by shaking 4 separate times with 50 cc. of $CHCl_3$ for 3 min. If the $CHCl_3$ form such an ext. is evapd. and the residue taken up in a little H_2SO_4 water, the loss

on extg. this soln. with ether amounts to 0.06% on 3 g. of tea. The development of these facts led P. to the following method: Transfer 3 g. of finely ground tea, weighed to within 5 mg., to a $\frac{1}{2}$ l. separatory funnel and add 10 cc. of NH_4OH . After a few min. add 50 cc. of CHCl_3 and shake for 3 min. Filter the CHCl_3 through a small folded filter (4 cm. diam.) into a 250 cc. Erlenmeyer flask containing several small pieces of pumice. Should the filtration become retarded the filter paper may be punctured with a fine wire. Add the second 50 cc. of CHCl_3 through the funnel used for filtering, pouring it rapidly enough to fill the filter to its edge, shake for 3 min. and filter into flask. Repeat twice. After evapg. the CHCl_3 on the H_2O bath add 120 cc. of H_2O and 20 cc. of 0.1 N H_2SO_4 or its equiv., and heat to boiling. Filter hot on a small filter and wash with H_2O . After cooling add 10 cc. NH_4OH and a few drops of phenolphthalein and ext. 4 times with 50 cc. portions of CHCl_3 , the pink color of the indicator making a sharp line of demarcation; then filter and wash as before except for piercing the filter. Evap. the CHCl_3 and transfer to small glass dish with a little CHCl_3 and dry in a water oven the flame of which has just been turned off. When dry sublime in P.'s app. A detn. of H_2O was made on 39 teas from China, Ceylon, India and Java with a min. of 6.87%, av. of 9.12% and a max. of 13.85%. A table of caffeine detns. on the same samples is given.

H. A. LEPPER.

Turning green of oysters and their content of heavy metals. F. LIEBERT. *Chem. Weekblad* 12, 978-83(1915).—The green color of certain varieties of oysters arises from wholly different causes. In the case of Marenne oysters the green color originates from the presence of certain algae, while in other cases this color may be due to a high content of Cu compds. Two samples of Truro oysters were analyzed by the author; the greener sample contained 0.244% Cu in the dry material, the less colored only 0.08%. A review of the literature is given.

J. T. FLOHL.

Determination of the water content of meat products. E. FEDER. Aix la Chapelle. *Chem. Ztg.* 40, 157-60(1916).—A discussion of Seel's criticism (*C. A.* 9, 3107) of F.'s "ratio no." (*C. A.* 7, 3170; 8, 3601) for H_2O in chopped meat and sausage. Cf. Schenck and Burmeister, *C. A.* 9, 1949.

J. H. MOORE.

The estimation of fat in food for infants. H. G. CHAPMAN. *Proc. Roy. Soc. N. S. Wales* 46, 469-72(1915).—A food for infants which contained 2.25% H_2O , 2.8% N, 3.55% ash, and 60% of carbohydrates, about $\frac{1}{6}$ of which was insol. in H_2O , when extd. in the Soxhlet app. with anhyd. Et_2O free from EtOH , yielded 7.4% fat. Redried and extd. again, less than 0.02% fat was obtained. Analyses run in quadruplicate checked closely. The same sample, extd. by the Röse-Gottlieb method, gave 16.85%, indicating that with this kind of foods it is impossible to det. the % of fat by the dry extn. methods.

H. S. BAILEY.

The relation of the composition of milk to cheese making. E. HAGLUND. *Kungl. Landtbruks-Akad. Handl. Tidskr.* 54, 583-609(1915).—The change in the total N of the milk does not change the distribution of the N between the cheese and whey. When the fat in the milk is increased there is an increased loss of fat in the whey, both relative and absolute. This loss cannot be corrected by changing the temp. of the milk in the process. Practical suggestions are given.

A. R. ROSE.

Pasteurizing milk by the method of prolonged heating at 60-64°. CHR. BARTHEL. *Kungl. Landtbruks-Akad. Handl. Tidskr.* 54, 610-48(1915). Influence of pasteurizing milk on the tubercle bacillus. CHR. BARTHEL AND O. STENSTRÖM. *Ibid* 649-61.—B. recommends that milk be pasteurized by heating to 60-64° for a period of 30 min. with const. stirring. This treatment changed the taste of the milk and the soly. of the milk albumins and Ca salts. Of the enzymes present the amylase was the only one destroyed. The peroxidase and aldehyde-reductase were not changed. 99.5%.

of the bacteria were destroyed including all the pathogenic and the lactic-acid-forming bact. Milk pasteurized in this way keeps 2 days and should be used within this time. *B. tuberculosis* were killed by heating the milk to 60° for 10 min. A. R. ROSK.

Chemical testing of milk and cream. ROSCOE H. SHAW. U. S. Dept. Agr., *Bur. of Animal Industry A-7*, 38 pp.(1916).—A publication designed for chemists and practical dairymen for the detn. of fat, total solids, sp. gr., acidity of milk and cream and the detection of preservatives. The chem. nature of milk is given. App. used is shown, together with tables of value in computing results. E. H. INGERSOLL.

Freezing of milk. C. BESANA. *L'industria lattiera e zootechnica* 13, 221(1915); through *Ann. chim. applicata* 4, 366.—On cooling milk till it freezes, there is not obtained a homogeneous mass; the lower layers are richer in solids except fats, which predominate in the upper layers; the interior of the mass is richer in solids than the peripheral layers. S. LEVY.

Enzymes of milk. C. BESANA. *L'industria lattiera e zootechnica* 13, 264(1915); through *Ann. chim. applicata* 4, 366.—The enzymes of milk are of 3 kinds: hydrolyzing, oxidizing, and reducing. S. LEVY.

Has light an effect upon the staling of bread? J. R. KATZ. Amsterdam. *Z. physiol. Chem.* 96, 288-91(1916).—As far as could be detd. light does not accelerate or retard the staling of bread. Cf. *C. A.* 9, 1808. C. J. WEST.

Remarkable property of aldehydes to prevent bread from becoming stale. J. R. KATZ. Amsterdam. *Z. physiol. Chem.* 96, 314-22(1916).—Aldehydes (formaldehyde, acetaldehyde, propylaldehyde, *n*-butylaldehyde, isobutylaldehyde and isovalerylaldehyde) are able to prevent bread from becoming stale for a period of at least 2 weeks. Ketones do not possess this property. C. J. WEST.

The political and technical relationship of the substitution of chemical aids for yeast in baking. A. KRAUS. *Chem. Ztg.* 39, 793-4(1915).—The use of yeast in bread-making causes a loss of 1.5-2% in nutritive value. In addition the manuf. of compressed yeast requires the use of maize, barley and malt. In order to aid in the conservation of breadmaking cereals, chem. substitutes for yeast were therefore sought. The best bread was obtained by using a cream of tartar baking powder, but a lactic acid and NaHCO₃ mixt. also gave satisfactory results. E. A. TSCHUDY.

Some overlooked investigations on wheat. W. P. HEADDEN. *J. Ind. Eng. Chem.* 8, 283(1916).—A report of expts. by H. Ritthausen and R. Potts, published in 1872, gives results very similar to those of H. (C. A. 9, 3320), whose article was published before he knew of this earlier work. It is surprizing that Ritthausen's investigation received no attention. H. S. BAILEY.

Tea seed oil (DEUSS) 27.

WOODMAN, A. G.: **Food Analysis: Typical Methods and the Interpretation of Results.** New York: McGraw-Hill Book Co. 510 pp. \$3.00.

Carameling chocolate. E. L. A. SAVY. U. S., 1,173,873, Feb. 29. A thin layer of chocolate is spread upon a rotating drum and treated with a counter-current of air heated to 100-140° to produce a carameling effect within a short time.

Iron added to foods, drugs or beverages. H. L. MARSH. U. S., 1,171,739, Feb. 15. Ferric succrate soln., free from alkali, is heated under pressure to 100-175° and the resulting prepn. is used for ferruginizing foods or beverages or directly as a medicine. The compn. forms no ppt. with most beverages and is free from any pronounced sweetish taste. Cf. *C. A.* 9, 1081.

Preserving potatoes. VEREIN DER SPIRITUSFABRIKANTEN. Ger., 286,106, May 30, 1914. The potatoes are grated raw and inoculated in waterproof pits with pure lactic acid cultures. Shredded or chopped sugar beet or beet-sugar molasses is added to the potatoes before souring, whereupon the potato slurry is warmed to a temp. suited to the lactic acid organism used. A sour mash, which is kept alive in the manner common for yeast cultures in distilleries is employed as the inoculating medium. *E. g.*, raw potatoes are reduced as in potato starch manuf. and pumped, as a slurry, into the souring pits. The addition of the inoculating material (1%) is made in course of the passage from the graters to the pits which are water-tight. After souring is complete, the pits are closed air-tight. If a warm lactic acid organism is used, the mass should be warmed to 50–55°. For the cultivation of the stock culture, a mash is prepd. from sacchariferous materials or materials saccharified by malt, or from non-saccharified potatoes, and the acid stock is transferred, in suitable amts., from one mash to the other. Should the potatoes not contain a sufficient amt. of sugar, molasses may be added.

Milk sterilizer. F. GÄRPHEIDE and H. HOFER. Ger., 286,539, Mar. 28, 1911. The sterilization is effected by the action of a const. high pressure, which can be instantly relieved, or by intermittent action of such pressure, upon the material under treatment.

Converting crystallized honey into sirup form. K. HAUER. Ger., 285,710, May 2, 1914.

Converting pulverulent, lumpy, or doughy starch into granular form. A. P. ANDERSON. Ger., 281,715, Aug. 18, 1912.

14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW.

Books on purification of water. *Munic. Eng.* 50, 56–7 (1916).—This is a brief bibliography of the leading books. LANGDON PEARSE.

Hints on the design and operation of intermittent sand filter. D. C. FABER. *Eng. Ext. Div.*, Iowa State College, *Bull.* 16 (1916); *Eng. Contr.* 45, 168–9 (1916).—Iowa practice uses 24 in. net depth of sand having a ridge bottom with valleys 6 in. deep, spaced 5 ft. on centers, containing open joint tile underdrains surrounded by gravel. From 100,000 to 500,000 gal. per acre per day are applied with doses 3 in. deep. High rates require const. care. LANGDON PEARSE.

Water softening by filtration. ANON. *Munic. Eng.* 50, 50 (1916).—Synthetic hydrous aluminium silicate (R. Gans) and a similar natural substance (R. N. Kinnaird) reduce hardness in the water during filtration. LANGDON PEARSE.

Hartford (Conn.) waterworks notes. C. M. SAVILLE. *Report Bd. Water Commrs.* 1915; *Munic. J.* 40, 333–4 (1916).—On account of the proximity of high-ways to reservoirs the water is sterilized before delivery. The raw water showed bacterial counts as high as 39,000 per cc. with *B. coli* found from 9 to 23 times in 10 cc. or less, every month. Treatment with 0.95 p. p. m. available Cl has removed *B. coli* and 99.8% of total bacteria. With CaOCl_2 , 1 p. p. m. available Cl was used or 25 lbs. of bleach per mil. gals. Liquid Cl used is 0.65 p. p. m. or 5.4 lbs. per mil. gal. LANGDON PEARSE.

Novel water-treatment plant at Excelsior Springs, Mo. ANON. *Eng. News* 75, 400–1 (1916).—The water supply contains total solids 527 p. p. m., including 420 p. p. m. HCO_3^- . Fe is also present. Treatment comprizes aeration followed by settling, pptn. by using lime, and rapid filtration. Aeration removes 59% CO_2 . 2.6 grains per gal. of lime reduces CO_2 and allows Fe to ppt. After 5 hrs. the water is fairly clear, the

CO₂ reduced to 11 p. p. m. and Fe to 0.2 before filtration. The filtered water contains Fe in less than 0.1 p. p. m.

LANGDON PEARSE.

Death resulting from typhoid fever held to be within the Wisconsin workmen's compensation laws. *Pub. Health Reports* 31, 329-34(1916); *Eng. News* 75, 426(1916).—The death of an employee was caused by typhoid fever contracted by drinking impure water furnished by the employer. The court decided that the death was the result of an accident and that the employer was liable under the Wisconsin law.

EDWARD BARTOW.

Water-borne typhoid at Westfield, N. Y. T. HORTON. *Health News* 10, 373-4 (1915).—The epidemic was caused by infection of water supply by a case of typhoid on the watershed, but was checked by the use of Cl.

J. GAUB.

The preparation of sterile drinking water in the field. *Pharm. Zentralhalle* 56, 49-55, 212-3(1915).—A review of methods employed in the German army.

C. O. EWING.

Field water purification plant. ANON. *Can. Engr.* 30, 189-90(1916).—A portable app. has a capacity of 3000 gals. per hr. A 9 h. p. gasoline engine drives a 2½-in. rotary pump and a 2½-kw. 220 volt d. c. generator. The water is pumped through a pressure filter, and is sterilized by ultraviolet rays.

LANGDON PEARSE.

Purification of water supplies. E. O. JORDAN. Univ. Chicago. *J. Am. Med. Assoc.* 66, 467-71(1916).—An address which gives a general review of water purification in the U. S., especially the more recent developments. Five tables and 10 references are included.

L. W. RIGGS.

Sanitary feature of Los Angeles aqueduct. B. A. HEINLEY. *Munic. J.* 40, 35-7(1916).—The water is brought in 233 miles from Owens River to Los Angeles. The density of the population in the watershed is 1.4 per sq. mi. In addition to the time in the aqueduct, reservoirs increase the normal storage period to 65 days and under present conditions to 468 days. *B. coli* noted were traced to ducks. The mineral content ranged from 15 to 22 grains per gal. Algae growths occasionally cause odors and taste, despite covered reservoirs on the distribution system.

LANGDON PEARSE.

Improving sanitary conditions on the Ashokan reservoir watershed. G. G. HONNESS. *J. N. E. W. W. Assn.* 29, 502-6(1915); *Eng. Contr.* 44, 213(1915).—A review of the methods used for the protection of the water supply of New York City.

S. T. POWELL.

Ground water in the Waterbury area, Connecticut. ARTHUR J. ELLIS. U. S. Geol. Survey, *Water Supply Paper* 397(1916).—The chief supply is in the glacial drift. The av. yield of wells in the cryst. rocks is about 15 gallons per min. Data in regard to supplies for each town are given.

W. D. C.

Water resources of Hawaii, 1913. G. K. LARRISON. U. S. Geol. Survey, *Water Supply Paper* 373(1915).—Discharge measurements are given for certain streams and ditches for 1913.

W. D. C.

Surface water supply of Oregon, 1878-1910. F. F. HENSHAW AND H. J. DEAN. U. S. Geol. Survey, *Water Supply Paper* 370(1915).—After a discussion of the natural features of Oregon, results are given of stream measurements for the time covered.

W. D. C.

Ground water in Paradise Valley, Arizona. O. E. MEINZER AND A. J. ELLIS. U. S. Geol. Survey, *Water Supply Paper* 375-B(1915).—A sketch of Paradise Valley is given with special reference to the underground waters as found in an investigation to discover a suitable supply for irrigation. It is concluded that while the yield and the ultimate supply of ground water will no doubt be found to be much less in Paradise Valley than in the Salt River Valley yet the prospects for obtaining dependable supplies

from underground sources for irrigation on a small scale are sufficiently encouraging to justify the sinking and testing of wells. W. D. COLLINS.

The relation of stream gaging to the science of hydraulics. C. H. PIERCE AND R. W. DAVENPORT. U. S. Geol. Survey, *Water Supply Paper* 375-C(1915).—The authors consider stream gaging as a branch of hydraulic engineering and conclude that, while a large amount of research is needed before hydraulics can be considered an exact science, yet the recent developments in stream gaging point to the possibility that this branch may in time reach such a state of perfection that all problems connected therewith may be solved with mathematical exactness. W. D. C.

Equipment for current-meter gaging stations. G. J. LYON. U. S. Geol. Survey, *Water Supply Paper* 371(1915).—Numerous plans accompany technical descriptions of types of equipment for current meter gaging stations that have been found most effective in facilitating observations and insuring accurate results. Tables give bills of material for parts of the equipment. W. D. C.

Stream-gaging stations and publications relating to water resources, 1885-1913. XII. North Pacific Slope drainage basins. B. D. WOOD. U. S. Geol. Survey, *Water Supply Paper* 340-L(1915); cf. C. A. 9, 2785.—Twelfth and last part of *Water Supply Paper* 340, containing a list of all gaging stations in the district covered and a list of all Survey publications relating to that section. W. D. C.

The fundamental principles of the activated sludge process of sewage treatment. T. C. HATTON. *Indiana San. and W. S. Assoc.* 1916; *Eng. Contr.* 45, 235-6(1916).—The activated sludge process depends on the presence of biological life in the sludge under aerobic conditions. LANGDON PEARSE.

The activated sludge process of sewage treatment. G. J. FOWLER. *Can. Eng.* 30, 227-8(1916).—F. sketches the historical development of the process, and dwells on the "M7" process of adding bacterial cultures in the presence of Fe in soln. Activated sludge has 3 broad actions: (1) a clotting or clarifying action, (2) a rapid carbon oxidizing process and (3) nitrification. Much research is still required. L. P.

British and American patents on activated sludge. T. C. HATTON. *Eng. News* 75, 189-90(1916).—U. S. patent 1,139,024 issued to L. C. Frank (cf. C. A. 9, 1647) and 4 English patents (Oct. 11, 1913 to Apr. 11, 1914) issued to Jones and Atwood have identical process and apparatus claims. Americans have developed continuous flow app. LANGDON PEARSE.

The activated sludge experiments at Salford. W. H. DUCKWORTH. *Surveyor* 48, 648-52(1915); *Assoc. Mgrs. Sewage Disposal Works* 1916; *Munic. J.* 40, 199-200(1916).—Continuation of the Salford expts. (cf. C. A. 9, 679) has given satisfactory purification of sewage with 2-hrs. blowing of air, even in winter, and part of the time with only 1 hour of aeration. The presence of trade wastes of a sterilizing nature at times necessitates longer periods of blowing to restore the activity of the sludge. Success with some of the air jets clogged up leads to the conclusion that a smaller amt. of air might be used. In continuous treatment 60,000 gallons per day are treated in an aeration tank of 12,000 gals. capacity with 4 tanks of 1,500 gals. capacity in series for recovery of sludge carried on from the aeration tank. From each of the first 2 settling tanks sludge is pumped back to the inlet of the aeration tank about 5 min. every $\frac{1}{2}$ hr., while the other 2 require pumping back only about 2 min. per week. Conclusions have not been reached in regard to cost of operation or disposal of excess sludge.

W. D. COLLINS.

Recent improvements in the construction of cultivation tanks. W. D. S. MONCRIEFF. *Surveyor* 48, 596-7(1915).—For the best results in conversion of org. substances into their inorg. equivs. it is necessary that bacterial processes be zonal in their

action and that the process be continuous without disturbance of the zones of activity. At Chertsey 300,000 gallons of sewage per day passed through "cultivation" tanks, 60 by 30 ft. by 3 ft. deep, for a month, forming only 7,000 gallons of sludge. The tank has a level perforated false floor, and the sewage passing under this floor moves upwards to the level of a series of 4 in. land drains laid in lines 2 ft. 6 in. apart, which pass through the further wall of the tank, and discharge into a channel that conveys the effluent to the distributors of the downward filters. The tank effluent was very unstable. The O-consumed figure fell automatically in 18 hrs. from 84 to 44 p. p. m. A sample of effluent from a cultivation tank followed by 3 ft. of downward filtration kept 7 years without further change. M. considers the process ideal for domestic sewage, as it is in keeping with the processes of nature, but the zonal action must be kept uniform.

W. D. COLLINS.

The disposal of sewage by dilution: a biochemical method of purification. W. E. ADENEY. *Surveyor* 48, 600-4(1915).—The general principles of purification by diln. with water containing O are set forth, with reference to the well known expts. recorded in the reports of the Royal Commission, the Metropolitan Sewage Commission of New York, and others. Attention is especially directed to the injurious effects of decomposing sewage solids settling in pools in water courses, to be washed out later by freshets. Normal sewage is not likely to exercise any poisonous action on a stream when mixed in safe proportions for oxidation. Trade wastes discharged raw might be poisonous, but it is common experience in biological purification works that they are not often present in sufficient quantity to cause trouble. A.'s definition of normal sewage is: "'Normal' sewage matters are refuse matters, the fermentable organic constituents (both in solution and in suspension) of which can be purified, without previous treatment of any kind, by living organisms."

W. D. COLLINS.

Sewage disposal by dilution. EDIT. *Surveyor* 48, 593-4(1915).—In discussing the paper by Adeney (cf. preceding abst.) it is pointed out that there are places where effluents discharged into large bodies of water are purified more than is necessary, but it is believed that in all cases provision should be made for max. removal of solids in suspension. So far as England is concerned "the number of rivers with a large minimum flow of highly oxygenated water is so small and the number of cases in which the only available outlets for sewage effluents consist of small rivers or streams is so large that in the majority of schemes it will still be necessary to provide filters and all other possible means of securing highly purified effluents."

W. D. COLLINS.

Eight years of Imhoff tank design and operation. KARL IMHOFF. *Eng. News* 75, 14-9, 52-5(1915).—In the past 8 yrs., 175 Imhoff tanks were built in Germany, and 70 in the United States. The best form of tank is the horizontal flow. Round sludge chambers are cheapest, and even round tanks may be cheaper. Deep tanks are preferable, as they produce denser sludge. Coarse screens with an opening of about 2 inches are necessary. A grit chamber is required in a large plant on a combined system. Velocities of 8 to 12 in. per sec. should be maintained. Three units are preferable. Where sludge is pumped a secondary tank is now provided, affording storage of 1 week. Sedimentation periods of 1.5 to 2 hrs. are provided, equiv. to 2.6 hrs. on the av. daily flow. The sludge chamber should have a capacity in cu. ft. *per capita* varying from 0.8 to 2.4 on separate systems, and 1.2 and 3.6 on combined systems. On an av. 1 sq. ft. of sludge drying area will serve 3 people. In operation, the walls of the settling chamber may require cleaning. The inclination should be 1.2 vertical to 1 horizontal. Ripened sludge is alk., black and odorless. The use of CaO to prevent acidity in the sludge is not advised. Proper decompn. depends upon the sludge. Sludge should be discharged every 2 to 6 weeks. The sludge level should be kept 3 feet below the slots. Sludge level may be detd. by lowering a thin sheet iron disc 12 in. in diam. Stirring the

sludge is helpful. Inoculation of new by old sludge favors proper decompn. A properly designed sedimentation plant should remove 95% of settling solids. Disinfection of sewage in the settling chamber is practical in the Imhoff tank. This may be followed by chem pptn.

LANGDON PEARSE.

Lime to correct acid sludge in Imhoff sewage tanks. W. L. STEVENSON. *Eng. News* 75, 430-1(1916).—At the Pennypack Creek Sewage works, the sewage of 4500 people is handled. The sludge dried slowly and was very acid, containing 2,200 parts per mil. acid to phenolphthalein. The addition of about 10 bu. of lime a month to a flow of 1.25 mil. gal. per day produced a good sludge, readily drying and of neutral reaction.

LANGDON PEARSE.

Discharge of sewage into streams. U. S. Pub. Health Reports 31, 421, 465-7 (1916).—The Supreme Court of Oregon decided that a municipality might discharge sewage into a stream in case the pollution did not cause a menace to health. (State Bd. of Health vs. City of Silverton, 71 Oreg. 379, 142 Pac. Rep. 609.) L. P.

Electrolytic sewage treatment in Boro of Queens. J. W. ROUTH. *Munic. Eng.* 50, 19-20(1916).—R. calls attention to discrepancies in published reports on Landreth app., principally in cost data which do not include essential cost of app. Degree of purification is not definitely established. Sludge disposal is not solved by the electrolytic process, as the amount is as large or larger than for chemical pptn., with equal quantities of lime. The tests at Elmhurst were made when the sewage was weakest. L. P.

Utilization of the constituents of city waste water. PAUL FISCHER, Fürstenwalde, AND E. BESSEMFELDER, Charlottenburg. *Chem. Ztg.* 40, 29-31(1916).—F. considers B.'s figures on the annual saving (cf. C. A. 10, 239) as being much too high, and thinks sewage could be more profitably used for feeding fish, for which a plan is outlined. B. replies.

J. H. MOORE.

Largest Imhoff tank plant nearly ready to treat Rochester's (N. Y.) sewage. C. A. POOLE. *Eng. Record* 73, 204-8(1916).—The plant consists of 6 detritus tanks, fine screens, and 10 Imhoff tanks. Construction features are detailed.

F. B.

Remodel septic tank into two-story tank. N. N. CAMPBELL. *Eng. Record* 73, 219(1916).—Lake Forest, Ill., tanks had outgrown their capacity. Cost of remodeling was \$4,000.

FRANK BACHMANN.

West Riding sewage disposal problems. Destructive trade effluents. ANON. *Surveyor* 48, 657(1915).—Acids discharged from picric acid works and explosives factories have damaged distributing systems and other machinery of sewage works so that the West Riding Rivers Board does not permit the discharge of such wastes directly into streams until measures have been taken to remove the acidity.

W. D. C.

Single house sewage disposal plant, Lewisville, Ark. *Eng. News* 75, 434(1916).—A three-section septic tank holding 150 gals.

LANGDON PEARSE.

Fish diseases in their relation to sewage. P. SCHIEMENZ. *Allg. Fischerei Ztg.* 13, 189-93, 201-8(1915); *Wasser u. Abwasser* 10, 109-10(1915).—The majority of diseases to which fish are subject are of parasitic origin. It is almost impossible to combat these diseases in large ponds and flowing waters. As a rule epidemics die out gradually. The influx of sewage is very detrimental. The org. content of the sewage deprives the water of its O. The sewage is much more readily digested in still water. The ice formed in winter prevents re-aeration. Potash liquors are harmless in flowing water. In stagnant water the salts diffuse to the bottom, thereby endangering fish-life, particularly in winter. In the discussion of the paper Hofer objects to S.'s views on the hopelessness of combating fish epidemics. He claims that an optimistic view is justified in the light of latest observations.

ARTHUR LEDERER.

Modern methods of garbage disposal in cities and villages. J. W. FOLIN. *Pub. Health, Mich. Bd. of Health* 3, 664-70(1915).—Av. Am. garbage contains 70% H_2O , 3% grease, 20% animal and vegetable matter other than grease, 7% rubbish or combustible matter and weighs from 1100 to 1200 lbs. per cu. yd. The various methods of disposal are discussed.

J. GAUB.

A new sampling apparatus for the determination of aerial dust. G. T. PALMER. *Am. J. Pub. Health* 6, 54-5(1916).—The app. consists of a glass bulb with tubular elongations at each end. The lower tube is U-shaped and in its lower part or trap are placed about 40 cc. of distd. H_2O . As air is exhausted from the upper end of the bulb by means of a No. 00 Sirocco blower, the H_2O is displaced from the U-tube and on reaching the bulb enlargement it breaks into a fine shower. The force of the air stream keeps the H_2O in constant spray formation and the air is washed free of its suspended matter as it passes through the shower. The air is measured by a special Venturi meter placed over the inlet of the U-stem. The manometer is calibrated in cu. ft. per min. After a run is completed the H_2O is decanted and the glass bulb rinsed with H_2O , making the total vol. up to 100 cc. The dust is then estd. either by comparing with a set of turbidity standards, counting the particles under the microscope or by weighing the solids after filtration through a Gooch crucible or after evapn. The app. weighs 17 lbs. The advantage of this app. over the sugar filter is that it is possible to collect large vols. of air; also the estn. of the dust is possible in more than one way. The sugar filter requires 7 hrs. to filter 100 cu. ft. of air, an amt. necessary for weighing purposes unless the air is very dusty. The new app. passes this amt. in 30 min. due to the resistance being less than in the case with pads of sugar, paper or cloth.

J. GAUB.

Tests on recirculation of washed air. G. L. LARSON. *Heating Vent. Mag.* Feb., 1916, No. 2, 36-7.—Conclusions are: 15 cu. ft. per min. per person is ample; humidity 50-70% and temp. 18.3° are comfortable; up to 20 parts CO_2 does not indicate bad air under these conditions; recirculation and air movement greatly reduce cost of heating; air washing removes dust and CO_2 but not bacteria. H. V. MAIN.

Ventilation standards. E. V. HILL. Chicago Health Dept. *Heating Vent. Mag.* 1916, No. 2, 40; cf. preceding abstract.—Chicago uses the following standards: 30 cu. ft. per person per min. with 2½ ft. per sec. velocity; CO_2 , 8 parts per 10,000; temp., 20°; humidity, 42%; dust count, 100,000 particles per cc.; bacteria, 12 colonies per plate.

H. V. MAIN.

The increase of the disinfecting strength with decrease of the toxicity of phenols. HANS FRIEDENTHAL. *Nikolasche. Berl. klin. Wochschr.* 52, 1019-22(1915).—Two new disinfectants, "sagrotan" which is chloroxyleneol, and "grotan" which is a complex *p*-chloro-*m*-cresol compd., form the subject of the discussion in this paper. It is shown that while they have a stronger bactericidal action than lysol, cresol, or phenol, they are not injurious to the skin and are comparatively non-toxic when taken internally. F. shows that just as lysol is better than phenol, so "sagrotan" is better than lysol and "grotan" is better than "sagrotan." It is believed that finally substituted phenols will be discovered that are so strong bactericidally and yet so little toxic that they can be used in the therapy of infectious diseases.

WATSON, M.: *Rural Sanitation in the Tropics.* London: J. Murray. 320 pp. 125.

Purifying water. J. W. BLOCK. U. S., 1,173,698, Feb. 29. In purifying H_2O by use of $Al_2(SO_4)_3$ as coagulant, Ti sulfate or other sol. Ti compd. is added to facilitate the pptn. of the coagulant.

Purifying water. F. R. WEBB and W. H. WEBB. Brit., 22,048, Nov. 5, 1914. Water is purified, decolorized, deodorized, and clarified by addition of bleaching powder or other hypochlorite followed by an acid salt such as $\text{Al}_2(\text{SO}_4)_3$ or $\text{Fe}_2(\text{SO}_4)_3$, or an acid such as H_2SO_4 , which reacts upon $\text{Ca}(\text{HCO}_3)_2$ in the H_2O to liberate CO_2 , which increases the decompn. of the bleaching powder. CO_2 or $\text{Ca}(\text{HCO}_3)_2$ may be added. The H_2O , after settling, may be passed through a series of perforated trays to remove residual CO_2 .

Purifying water for use in brewing. E. JALOWETZ, E. RICHTER and A. SCHURCKNER. U. S., 1,172,998, Feb. 22. CaCO_3 and MgCO_3 are removed from the H_2O immediately after pptn. which is effected by heating, with vigorous agitation, in an open vessel exposed to the air.

Purifying water for use in brewing. E. JALOWETZ, E. RICHTER and A. SCHURCKNER. U. S., 1,172,528, Feb. 22. MgCO_3 and other insol. carbonates are pptd. from H_2O by heating, with simultaneous vigorous agitation, to a temp. above the b. p., in a closed vessel.

Apparatus for purifying water by chemical treatment. E. CLAUSSEN. U. S., 1,173,709, Feb. 29.

Filter containing carbon for purifying water. MALACAPIT-GES. M. B. H. Ger., 286,428, May 14, 1912. The carrier for the C is satd. with broken down albuminous matter in aq. soln., ignited, cooled, washed, and then mixed with a ppt. of hydroxides of Fe, Al, Mn, Ni, or Co, and charged with CaCO_3 , by means of reagents which give these ppts. E. g., granulated porous fire brick are satd. with a 5% aq. soln. of peptone obtained by the action of alkali on albumin, dried, ignited, cooled and washed, and then satd. with solns. of salts of Fe, Al, Mn, Ni, or Co. Pptn. is effected then with lime water to which gypsum has been added, obtaining hydroxides, and then CaCO_3 is pptd. by means of a sol. carbonate acting on the gypsum.

Apparatus for removing iron from water. J. ZÖLLNER. Ger., 286,295, July 30, 1913. The removal of Fe is effected by means of atm. O, and the H_2O is then filtered. Suitable construction is specified.

Boiler feed-water purifier. H. HELLER. Ger., 285,992, July 12, 1914. The H_2O , flowing over plates arranged one above the other, is heated by means of boiler steam.

Purifying sewage. W. M. BECKETT. Brit., 21,985, Nov. 4, 1914. In purifying sewage by aeration, air is passed into closed sewage tanks under such pressure that, after passage through the sewage, it retains a pressure greater than atm., and the air together with gases evolved from the sewage is used as a blast for a steam generator furnace, refuse destructor, or gas producer. The sewage, after passing through a detritus tank, is passed into closed tanks having air-supply pipes leading to a pervious bottom formed of porous tiles, perforated plates, or pipes, etc.

Purifying sewage. W. JONES and JONES & ATTWOOD. Brit., 21,976, Nov. 4, 1914. Purifying sewage by aerating it in the presence of bacterial sludge which may be obtained by passing air in small bubbles through raw sewage and aerating the sludge obtained in presence of further quantities of sewage, or by aerating sewage in presence of humus obtained from filter beds. The sewage is aerated in presence of a third to a half of its vol. of sludge for 1-5 hrs. After settling, the clear liquid is withdrawn from the surface, and any excess of sludge is removed. The aeration is carried out by forcing air through porous bodies, such as porous earthenware, textile fabrics, coconut fiber, or Pb wool. A suitable app. is shown.

Mixtures of formaldehyde and steam for disinfection. G. A. RANFT. Ger., 285,262, Sept. 24, 1912. A practically full yield of HCHO in aq. soln. or admixt. with steam may be obtained from polymeric HCHO (paraform, trioxymethylene), under

ordinary pressure, by heating mixts. of H_2O and polymeric $HCHO$, with the addition of glycerol, in open vessels. *E. g.*, paraform 5 g., H_2O 25 cc., and glycerol 4 cc., are heated in an open vessel, or steam is conducted through a mixt. of paraform 5 g. and glycerol 4 cc.

Vacuum disinfection. APPARATEBAUANSTALT UND METALLWERKE AKT.-GES. Ger., 286,130, July 22, 1913. Addition to 284,972. A plurality of suitable small vessels, serving as containers for various solid or pulverulent disinfectants, are connected with the vacuum vessel in such manner that, upon heating a particular vessel, a desired disinfecting vapor is generated.

15. SOILS AND FERTILIZERS.

R. O. E. DAVIS.

Agricultural chemistry and vegetable physiology. N. H. J. MILLER. *Ann. Repts. Progress Chem. (London)* 11, 213-37(1914).—Investigations during 1914 relating mainly to soils and plant nutrition are reviewed. E. J. C.

The sphere of adsorption phenomena in the soil. A. N. SOKOLOVSKIY. *Zhur. Opytn. Agron.* 15, 67-117(1914); *Expt. Sta. Record* 33, 22-3(1915).—Studies are reported of adsorption phenomena in the different layers of chernozem and podzol soils, with particular reference to their nature and the factors conditioning them. The adsorptive power for bases was found, with 1 or 2 exceptions, to bear a close relation to hygroscopicity, and the activity of both factors decreased at higher temps. It is pointed out that water content, excluding the influence of salts, is a function of the so-called specific surface of the soil and increases with it. Adsorption appeared to bear no relation to the amt. of zeolitic constituents or the amt. of silt present. The amt. of NH_3 adsorbed from NH_4Cl varied with the soil layers according to the quantity of displaced bases. Adsorption with exchange of bases occurred to a rather low limit, beyond which the exchange of bases ceased. The adsorption of NH_3 varied with the amt. of dry residue obtained by displacing the soil soln. with 96% alc. The soil components which determine adsorption are characterized by a great specific surface and a susceptibility to thermal and chem. influences, and the adsorption phenomena beyond a certain limit are not accompanied by exchange reactions. The max. specific surface and the max. susceptibility to thermal influence are found in the upper soil section in which the colloid formation processes are most intensive, thus showing a specific relation between adsorption and the soil colloids. On the assumption that the thickness of the water film on the soil particles remains constant, the following conclusions are drawn: The adsorptive power of the adsorbing medium decreases with a decrease in its effective surface. The adsorption of Ca in the different layers of chernozem soil depends on the content of Ca which is already adsorbed and is displaced by NH_4Cl soln. and not on its total Ca content. The podzol soil, on account of its extremely leached-out condition and poverty in adsorbed matter, shows a series of concordant results for P_2O_5 , as well as for bases. Chernozem, on the other hand, on account of its complex formation, produces a regular series of results only for NH_3 . Removal of humus by oxidation with acid-free H_2O_2 showed that for chernozem, humus, even in the layers rich in it, did not appear to be an exclusive factor of adsorption. In podzol soils the decrease in NH_3 adsorption due to this treatment amounted to 65% of the original quantity.

W. H. FRY.

The effect of removing the soluble humus from a soil on its productiveness. WILLIAM WEIR. Rothamsted Expt. Sta. *J. Agr. Sci.* 7, 246-53(1915).—Sol. humus was removed from soil by washing with dil. HCl and was then repeatedly extd. with

dil. NaOH. Some 40% of the N was thereby removed. Vegetation expts. on both untreated and extd. soils showed that the removal of the sol. humus had no effect in diminishing the productiveness of the soil in spite of the fact that the soil used was known to respond to nitrogenous fertilizers. Lab. expts. indicated that the removal of the sol. humus increased the amt. of NH_3 but diminished that of nitrates produced in the soil, and that the sum of NH_3 and nitrates was usually less than in the untreated soil. The number of bacteria, however, was considerably increased. No marked difference was produced in case 0.5% untreated soil was added to replace the bacterial flora that might have been destroyed by the acid and alkali treatment.

W. H. FRY.

Correlation between humus and mineral matter in dark colored soils. A. A. BLAGONRAVOV. *Zhur. Opytn. Agron.* 14, 457-8(1913); through *Expt. Sta. Record* 33, 720(1915).—Assuming that degraded dark-colored soils have been at one time less degraded and comparing their chem. compn. by calcg. the % compn. of the zeolitic portion, it is found that the changes in the mineral part of these soils correspond with the changes of the humus content. On this basis, and assuming that the CaO is carried from the higher horizons downward in the form of Ca crenate, a series of "simple correlations" is calcd. between the CaO and crenic acid, for which Mulder's formula, $\text{C}_{24}\text{H}_{20}\text{O}_{14}$, is taken. With the aid of these correlations it is considered possible, from the difference in the humus of any 2 soils and the amt. of CaO in one, to calc. the content of the zeolitic lime in the other. The values so calcd. differ from those found by actual analysis only in hundredths of 1%. Other constituents of the zeolitic portion are also found by means of calcns. from a whole series of ratios. On the basis of correlations between different elements so obtained the difference in the compn. of 2 soils is expressed in the form of formulas by the aid of which, having previously detd. the CaO, the contents of all the other constituents are calcd. Then accepting for humic acid Detmer's formula $\text{C}_{60}\text{H}_{44}\text{O}_{17}$, the ratios to humic acid of the various bases sol. in 10% HCl are found and from these ratios, guided again by the relation between humus and CaO (1:4), a formula is deduced for the compn. of the mineral constituents of a given soil. Soils of different regions are reduced to a small number of groups, the criterion being the ratio of the amt. of C in the humus to the sum of mineral substances (from 10% HCl soln.).

W. H. FRY.

Quantitative media for the estimation of bacteria in soils. R. C. COOK. *Soil Science* 1, 153-61(1916).—Na asparaginate agar, albumin agar, and urea- NH_4NO_3 agar will give a greater colony development than other media in common use for bacteriological work. The albumin agar in which the albumin is dissolved in NaOH will give more consistent results than if the albumin is used in an aq. soln. A 5-day incubation period gave higher bacterial counts than a 3-day period. Sterilization either by flowing steam or at a pressure of 1 atm. will give equally good results.

J. J. SKINNER.

Studies in soil protozoa. S. A. WAKSMAN. *Soil Science* 1, 135-52(1916).—Moisture, humus content and the structure of the soil are the important factors governing the activities of the protozoa; sterilization of soil and addition of sol. org. matter will make the conditions optimum for protozoan activities at lower moisture content than the corresponding unsterilized or untreated soils. The flagellates are the most common soil protozoa found active in the soil with moisture content too low for the development of the other groups. The flagellates are the largest group and the greatest number are found just below the surface. The ciliates are found at a depth of 4 in., the number decreasing with depth; below 12 in. the soil is practically free from protozoa. Protozoa do not have any appreciable influence upon ammonification by bacteria. The presence of protozoa acts detrimentally upon bacterial numbers. The detrimental effect of the protozoa upon bacterial number, their non-detrimental and even beneficial

effects upon the soil, and their influence upon ammonification might be explained by (1) destruction of bacteria and non-ammonifying organisms; (2) the protozoa themselves taking part in the process of ammonification; or (3) the disintegration of bacterial cells resulting in decompn. products which might be responsible for high NH_3 production.

J. J. SKINNER.

The Actinomyces of the soil. S. A. WAKSMAN AND R. E. CURTIS. *Soil Science* 1, 99-134(1916).—The work was conducted with the purpose of demonstrating the occurrence of *Actinomyces* in different soil types, at different depths and under different cultural and climatic conditions. Soils from N. J., Oregon and California were studied. The number of *Actinomyces* and bacteria are greatest in the surface soil, but while the bacteria decrease rapidly below a depth of 4 in. the number of *Actinomyces* is practically constant at depths from 8 to 30 in. in humid soils. There is a striking difference between humid and semi-arid soil. In the surface 8 in. of the N. J. soils studied, *Actinomyces* make up an av. of 14.2% of the micro-flora exclusive of the higher fungi, while in the Cal. soil this av. is 26.8%, which indicates that semi-arid surface soils are relatively much richer in *Actinomyces* than are those of humid regions. Over 100 organisms have been isolated from the soil. These represent 30 species, which are described. The morphology and physiology of the organism were studied. A review of the literature is given.

J. J. SKINNER.

Observations on the formation and layer distribution of nitrates in soils with different nitrogen fertilizers. V. I. TKACHENKO. *Khosialstvo* Nos. 37-40(1912); *Zhur. Opytn. Agron.* 14, 585(1913); through *Expt. Sta. Record* 33, 422-3(1915).—In a study of the amt. and distribution of nitrates at different depths in the soil from June 27 to Sept. 9, 1911, and from April 8 to May 10, 1912, it was found that the minimum amt. of nitrate was present in the latter part of Aug. and the earlier part of Sept., but no direct connection between nitrate and temp. and moisture was observed. Fertilizing with NaNO_3 in general increased the nitrate content of the soil, but not in all cases. Cyanamide and $(\text{NH}_4)_2\text{SO}_4$ increased the accumulation of nitrates in the soil to a greater extent than NaNO_3 . There was little leaching of nitrates during rainy periods and this was not noticeable in any case below 25 to 50 cm. The observations in the spring of 1912 were made on the same plats used in the earlier expts. which had in the meantime been seeded to winter wheat. In general, considerably less nitrate was found than during the preceding summer. The loss of nitrates by leaching was less pronounced on plats fertilized with nitrogenous materials and which, therefore, had a heavier growth of wheat.

W. H. FRY.

The question of the formation of secondary minerals in the ortstein-producing horizons of soils. B. B. POLYNOV. *Esheg. Geol. Min. Rossii* 14, 273-80(1912); *Zhur. Opytn. Agron.* 15, 228(1914); through *Expt. Sta. Record* 33, 814(1915).—A brief morphological description and mechanical and chem. analyses of each layer of 2 podzol soils are reported. A marked increase in absorptive power and in amt. of sesquioxides, chemically combined water, alk. earths, K, and mechanical clay (less than 0.01 mm.) was observed in the ortstein-producing subhorizons as compared with the upper horizons. The increase in absorptive power for NH_3 is attributed to the presence in the ortstein-producing layers of "secondary soil minerals," such as the colloidal hydrates of SiO_2 and Fe_2O_3 , which have a high absorptive power for NH_3 , and also to accumulations in these layers of zeolite-like secondary hydrous Al silicates of Mg, K, and Ca.

W. H. FRY.

The action of gaseous ammonia on superphosphate and the use of the ammonium and phosphate salts thus obtained. GERLACH. *Z. angew. Chem.* 29, I, 13-4, 18-20 (1916).—When gaseous NH_3 is allowed to act upon superphosphate, an exothermic reaction occurs, and the NH_3 is rapidly absorbed. The products of this reaction, due

to the presence of gypsum in the superphosphate, are Ca phosphate and $(\text{NH}_4)_2\text{SO}_4$. If the superphosphate is placed in a slowly rotated drum, and the NH_3 passed through this, most of the NH_3 will combine in a very short time. The mass left in the drum after the reaction has ceased is dry and can be ground fine with ease. An analysis of the product thus prep'd. shows its compn. to be as follows: Water (hygroscopic) 3.42. $(\text{NH}_4)_2\text{SO}_4$ 33.71, di-Ca phosphate (2 mols. water) 2.74, tri-Ca phosphate 30.10, gypsum 22.55. Fe and Al phosphates 2.96, insol. 4.26, total 99.74%. No NH_3 is lost even after months of storage. Treatment with NH_3 converts most of the sol. phosphoric acid contained in the superphosphate into a form insol. or difficultly sol. in water. In cold water satd. with CO_2 , however, the phosphates thus formed are sol. Expts. made by using the NH_3 and phosphate salts thus obtained as fertilizer for oats showed the superiority of this material over superphosphate containing NH_3 salts admixed.

E. A. TSCHUDY.

Some chemical and agricultural effects of fertilizer mixtures containing calcium cyanamide. C. J. KING. *Com. Fert.* 10, 14-6(1915); *Expt. Sta. Record* 33, 25.—Continuing previous work by Brackett (*C. A.* 7, 4036) the author studied changes in the sol. P_2O_5 and N content in mixts. of acid phosphate, Ca cyanamide and KCl, and also the effect of such mixts. on the growth of cotton. The results confirm those of previous expts. in showing that there was considerable reversion of P_2O_5 in the mixts. after standing a few months. After 6 months of storage the amt. of insol. P_2O_5 had increased from 0.4 to 2.01%. There was no appreciable loss of N in that time. The field tests of the mixts. on cotton indicated a depreciation in their fertilizing effect within one month after the mixts. were made.

E. J. C.

The phosphatic deposits of Perlis (Malay States). W. *Indische Mercur* 38, 133-5(1915); *Bull. Agr. Intelligence* 6, 1038-40(1915).—The deposits occur in large open caves on the hillsides, and consist of dry sandy material of a light gray color with occasional black or yellow veins. The origin is probably purely mineral. The P_2O_5 is mainly in the form of CaHPO_4 or $\text{Ca}_3(\text{PO}_4)_2$. Some analyses have shown N, usually not exceeding 1%, probably due to the excrement of birds. The N does not notably increase the market value of the phosphate. A large portion of the P_2O_5 is sol. in weak acids, resembling that of basic slag; it acts more rapidly than that of bone meal. Analyses and expts. are given, the av. P_2O_5 content being about 18%. F. W. S.

Connection between the composition of Javanese tobacco and that of the soil on which it grows. N. H. COHEN. *Proefstation voor Vorstenlandsche Taback. Mededeeling*, No. 11, 18 pp.(1914); *Bull. Agr. Intelligence* 6, 1064-5.—Chem. and mechan. analyses have been made of samples of 20 Javanese tobacco soils. The samples were taken to a depth of 9 in. for the surface soil, and from 9 to 15 in. for the subsoil; the following detns. were made: potash sol. in 25% HCl, P_2O_5 , lime (surface soil only). P_2O_5 sol. in 2% citric acid, lime sol. in 10% NH_4Cl . Detns. for the tobacco included: ash, K_2O , P_2O_5 , CaO, MgO and Cl; in addition, the exact color of the ash was detd. by a scale of 10 shades of gray obtained by mixing 5, 10, etc., up to 50% of animal charcoal with CaCO_3 . It was found that: (1) The citric acid-sol. P_2O_5 decreases as the soil becomes heavier and more disintegrated. (2) The content of so-called "available" lime in the various soils is proportional to the amt. of the "very fine" fraction of the soil. (3) The proportion between the lime sol. in 25% HCl and the amt. of "available" lime is in inverse ratio to the amt. of "very fine" soil and approaches unity. (4) There is no connection between the amts. of K_2O present in the tobacco and the soil, resp. (5) There seems to be some relation between the amt. of P_2O_5 in the tobacco and in the soil; heavy soils poor in citric acid-sol. P_2O_5 produce a tobacco with a lower phosphate content than tobaccos grown on light soils. (6) There is a certain connection between "available" lime in the soil and the lime content of the tobacco. (7) In the case of the

tobacco, no connection could be established between Cl and potash contents and combustibility. (8) On the other hand, some connection exists between the lime content and the color of the ash; the higher the lime content, the lighter the color of the ash. (9) There is no certain connection between the amt. of MgO present in tobacco and the color of the ash. E. J. C.

Fertilizing with catalytic substances of vine ash. S. CETTOLINI. *Bol. quind. soc. agr. ital.* 20, 431-8(1915); *Expt. Sta. Record* 33, 841.—Data are given and discussed showing the effect on the quantity and compn. of the must and wine of grapes fertilized with CaSO_4 , $\text{Al}_2(\text{SO}_4)_3$, MgSO_4 , KMnO_4 , Fe_2SO_4 , NaCl and S, resp. E. J. C.

The action of sulfur on crops. T. PFEIFFER AND W. SIMMERMACHER. *Landw. Ztg.* 64, 243-55(1915); *Bull. Agr. Intelligence* 6, 1044.—These results indicate that S has no favorable after-effect on yield and may have a slight unfavorable effect on N-utilization. E. J. C.

The action of common salt and kainite applied with ammonium sulfate and sodium nitrate. SCHNEIDEWIND. *Landw. Wochschr. Provinz Sachsen* [1] 17, 3-5(1915); *Bull. Agr. Intelligence* 6, 810.—Considering that the particularly favorable action of NaNO_3 on beets is due partly to the Na, an attempt was made to increase the efficiency of $(\text{NH}_4)_2\text{SO}_4$ by the addition of NaCl. The expts. showed that a mixt. of the 2 salts gave better results than the $(\text{NH}_4)_2\text{SO}_4$ alone. E. J. C.

The influence of zinc vessels in culture experiments. K. GHEDROIZ. *Selsk. Khoz. Liesof.* 345, 625-7(1914); *Bull. Agr. Intelligence* 6, 57-8(1915); *Expt. Sta. Record* 33, 623-4(1915).—Pot expts. during 3 years showed that ZnSO_4 and ZnCl_2 had almost the same effect on the growth of mustard. The effect on barley differed from that observed in the case of mustard, as with 0.02% Zn the growth of mustard ceased, while barley gave a relatively good yield. Zn in very small quantities, however, stimulated the growth of mustard, but had a depressing effect on barley. Long-continued expts. with Zn pots showed that red clover grown in acid soils lost its germinating power and made feeble growth in the 3rd year. The injurious effect of the Zn pots was apparent in the case of clover in the 2nd year. It was most pronounced in the case of acid soils. W. H. FRY.

Factors influencing the protein content of soy beans. J. G. LIPMAN AND A. W. BLAIR. *Soil Science* 1, 171-8(1916).—Thicker planting of soy beans caused an increased utilization of atm. N by means of symbiotic bacteria. Nodule formation is not depressed by N fertilizers. The amt. of N in a number of different varieties of soy bean grown in pots was detd. J. J. SKINNER.

Soy beans. N. GILL. *Ann. Rept. Kumaun Govt. Gardens* 1913-14, 2-4; *Expt. Sta. Record* 32, 830.—This article gives the results of tests with several varieties of soy beans on soils, the chem. and phys. analyses of which are given. The data show yields, oil percentage, moisture, ash content and wt. of 100 seeds. E. J. C.

The insecticidal properties of various sulfides and polysulfides. P. J. PARROTT AND W. J. SCHOENE. *J. Econ. Entomology* 8, 204-5.—The amt. of S in proprietary insecticides contg. sulfides and polysulfides of the different bases varies greatly, ranging for the Na prepn. from 1.79 to 58.92%, K 2.39 to 38.72%, Ca 3.97 to 26.4%, and Ba 16.54 to 44%. The work so far points in general to the conclusion that the strength of a prepn. with regard to its S content is a more important consideration than the nature of the base of the sulfides and polysulfides. E. J. C.

Note on lime and sulfur. D. R. EDWARDS-KER. *J. Southeast. Agr. Col. Wye* 1913, 368-70; *Expt. Sta. Record* 34, 51.—From expts. with lime and S mixed intimately for use as a fungicide, it is concluded that there is no chem. action on mixing either quicklime or slaked lime with flowers of S. Consequently, considered from a chem.

point of view, there is no obvious advantage in adding lime to this form of S when designed for use as a fungicide. E. J. C.

The theory of wetting, and the determination of the wetting power of dipping and spraying fluids containing a soap basis. W. F. COOPER AND W. H. NUTTALL. Watford. *J. Agr. Sci.* 7, 219-39(1915).—In the detn. of the wetting power of a dip or spray fluid, a thick paraffin oil (liquid vaseline), free from acid, was taken as a standard to represent the greasy surface, *e. g.*, a greasy hide or a waxy leaf. The surface tension of this was detd. once for all. To compare the wetting power of any 2 preps., it was then only necessary to det. their surface tensions and their respective interfacial tensions towards the standard oil, and to substitute these values in the equation $T_2 - (T_1 + T_{12}) = \text{wetting power}$, where T_2 is the surface tension of the oil, T_1 that of the prep., and T_{12} the interfacial tension. Various examples of the application of this method are given. A short bibliography is appended. W. H. FRV.

Wetting sprays. V. VERMOREL. *Prog. agr. vit.* 35, 180-2(1914); *Expt. Sta. Record* 33, 450.—Gelatin added to sprays gives them excellent spreading and wetting qualities and perfect adherence. Casein is one of the best agents for use to increase the wetting capacity of a spray, and to leave almost entirely intact the chem. compn. of the Cu ppt., which it is adapted to distribute and fix upon the leaves. E. J. C.

KNOX, G. D.: *The Spirit of the Soil: or An Account of Nitrogen Fixation in the Soil by Bacteria and of the Production of Auximones in Bacterized Peat.* London: Constable & Co. 242 pp. 2s, 6d.

MCCALL, A. G.: *Field and Laboratory Studies of Soils.* New York: Wiley. 77 pp. \$0.60.

Fertilizer. A. J. GRINBERG and B. FELDMAN. U. S., 1,172,021, Feb. 15. A mixt. of bran 6 oz., sawdust 6 oz., CaO 1 oz., corn starch 4 drams, dil. NH_4OH 4 drams, H_2O 1 qt. with sufficient Fe scrap to produce heating by oxidation, is added to the soil around plants, in amt. equal to about 2% of the wt. of the soil near the roots, and further quantities of H_2O , corn starch and NH_4OH are added from time to time. Phosphates and nitrates are rendered available by fermentation.

Fertilizer. S. B. NEWBERRY and H. N. BARRETT. U. S., 1,173,303, Feb. 29. A citrate-sol. fertilizer is made by mixing natural phosphate with 5-25% of NaHSO_4 or KHSO_4 and heating the mixt. at about 1400-1500° for 20-70 min. to decompose the bisulfate and drive off SO_2 .

Fertilizer. F. S. WASHBURN. Can., 165,845, Nov. 2, 1915. A fertilizer containing N and P combined as a double salt in a form available as a plant food, and K intimately associated therewith also in an available form.

Fertilizer. F. S. WASHBURN. Can., 165,846, Nov. 2, 1915. Fertilizers containing N, P and K in forms available as plant food are produced by providing a double compound of NH_3 and P containing N and P in available forms, and adding thereto a residue containing K_2O , SiO_2 and Al_2O_3 obtained as an intimate mixt. after roasting the mineral alunite.

Fertilizer from phosphate rock. H. P. BASSETT. U. S., 1,172,420, Feb. 22. A mixt. of feldspar 50, NaHSO_4 100 and C 1-3 parts is heated to redness and the fumes given off are used to react upon phosphate rock, which is maintained at a temp. of 100-200°, to form available acid phosphate.

Treating grain and seeds. C. E. DE WOLF and H. E. FRY. *Brit.*, 21,888, Nov. 2, 1914. Treating grain and seeds before sowing by steeping them in a soln. of organic or chem. fertilizer (including Zn salts, H_2SO_4 , HCl, and H_3PO_4) with a salt of Fe, e. g., $FeCl_3$, or a soln. of NaCl, $Ca(NO_3)_2$, nitrolime, or HNO_3 or HNO_2 , with or without a salt of Fe, and then spraying with petroleum or benzoline. Cf. C. A. 9, 2790.

16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

Determination of essences in vermouth. X. ROCQUES. *Ann. chim. anal.* 21, 35-8(1916).—Vermouth of the French type is prepd. from white wine to which a small quantity of a sweet wine is added; the alc. strength of 18% is obtained by the addition of pure alc. Flavoring is effected by maceration of the herbs in the wine. R. sought to decide the question whether or not vermouth is to be classified among the beverages flavored by essences (for only in this case is it subject to special taxation). In a sample of wine intended for the manuf. of vermouth, the volatile I-absorbing constituents were detd. before and after flavoring. The flavoring effected only a minute increase in the I-absorption of the distillate. A gravimetric detn. of the essential oil in vermouth (cordial) gave a similar result. Both results lead to the conclusion that the proportion of essences contained in vermouth (cordial) is negligible. The expts. further revealed that by the titration of the essences (by I-soln.) only part of the SO_2 content is found.

L. W. HAAS.

Detection and determination of citric acid in wine. F. SCHAFER and E. GURY. *Mitt. lebensm. Hyg.* 6, 247-51(1915).—S. and G. have modified various methods for citric acid detn. which are based on Denigès' test. Make 25 cc. of wine alk. with NH_4OH , evap. on water bath to 10 cc., add 10 cc. of 7% $CuSO_4$ and evap. to 10-15 cc. After cooling transfer to a 25 cc. flask and complete the vol. with H_2O . Filter on dry paper, add 1-1.5 cc. of Denigès' reagent to 10 cc. of the filtrate, and heat to boiling. After boiling and filtering into an Erlenmeyer flask, heat again to boiling and add drop by drop 1% $KMnO_4$ until the Mn oxides begin to sep. Remove these with a few drops of H_2O_2 . Centrifuge the soln. and ppt. in a graduated centrifuge cylinder for 5 min. at 1000-1200 r. p. m. The number of cc. of ppt. $\times 0.021$ equals the citric acid in g. per l. of wine. The ppt. may be identified by the test of Baier and Neumann (C. A. 9, 2685). Small quantities of ppt. treated directly with Fe_2Cl_3 will give a red coloration. S. and G. confirm the statement of Kunz (C. A. 9, 687) that some wines naturally contain as much as 0.08% of citric acid.

H. A. LEPPER.

Wines of the harvest of 1914. G. FILANDEAU. *Ann. fals.* 8, 363-72(1915).—A discussion of the characteristics of the 1914 wines from various districts of France. Much less data are given in this report than in former years, so that generalizations are impractical.

H. S. BAILEY.

Analyses of some Roumanian wines of the 1914 vintage. AL. NITESCO. *Ann. fals.* 8, 416(1915).—A table giving analyses of 15 Roumanian wines.

H. S. B.

Study on the variation of the principal acids of the juice of the grape during the process of maturation. E. GARINO-CANINA. *Ann. r. accad. agr. Torino* 57, 233-90(1914); *Expt. Sta. Record* 34, 43.—The expts. here reported in detail included a phys. and chem. study of the changes taking place in the juice of different varieties of grapes during maturation and during the formation of wine.

E. J. C.

Distillation of cider apples. E. SAILLARD. *Mon. sci.* [5] 6, 25-9(1916).—The article is an official report on the standing of the production of alc. from cider apples. S. finds it possible to work up apples in sugar-beet distilleries, but some more experience

is desirable. A short description of the working processes for cider apples alone and as adjunct to sugar beets is included. L. W. HAAS.

17. PHARMACEUTICAL CHEMISTRY.

M. I. WILBERT.

The manufacture of pharmaceutical preparations, and means for assuring its development in France. Report of a conference held by the society for the fostering of national industries. E. FOURNEAU. *Ann. fals.* 8, 403-11 (1915). H. S. B.

The papaw and papain. H. F. MACMILLAN. *Tropical Agriculturist* 44, 179-84 (1915); *Bull. Agr. Intelligence* 6, 1066.—Some notes are given on the cultivation of the papaw tree and the prepn. and commerce of papain. Cf. *C. A.* 9, 1529.

E. J. C.

Injection gelatin. HANS TRUNKEL. *Pharm. Ztg.* 61, 65-6 (1916).—The following procedure is recommended for the production of gelatin suited to injection: Dissolve in the steam bath 200 g. best gelatin in 800 cc. H₂O, using for the purpose a 2 liter Jena flask covered with a glass plate. After soln., neutralize with 30 cc. N NaOH. Cool to 45°, stir into the soln. the beaten whites of 4 eggs and heat the covered beaker 90 min. in a sterilizer; then pass through a double folded filter (using a hot water funnel) into a Jena 2 liter flask having a mark for 1000 cc. Return the first 100 cc. to the main portion, continue the filtering operation to completion, finally washing with H₂O sufficient to yield 1000 cc. filtrate. Treat the soln. 3 hrs. with CO₂ at 37° without transferring the liquid to another container. The delivery-tube passing through a 2-holed stopper reaches to the bottom of flask while the exit hole carries a drying tube filled with cotton. Add 5 g. acid carbollic liq., mix thoroughly, fill into suitable container and sterilize immediately at 60° and again at 60° after 24 hrs. W. O. E.

The uses of amyl acetate. T. H. DURRAN. *J. Chem. Technology; through Chemist Druggist* 88, 181-2 (1916).—An article dealing with the industrial applications of amyl acetate. C. O. EWING.

Oil of *Librocedrus decurrens*. ANON. *Perfumery Essent. Oil Record* 6, 214 (1915).—The oil from the needles of *Librocedrus decurrens*, a California conifer, has a sp. gr. of 0.8756, $[\alpha]$ —0° 51', and $n = 1.47544$. It dissolves in 7 vols. of 90% alc. with turbidity. About 22% of the oil passes over at 158-60°. This fraction has a sp. gr. of 0.864 and $[\alpha] = -18^\circ 40'$. It contains a considerable amt. of *l*- α -pinene. In the fraction b₁₆ 60-8°, β -pinene was identified. The higher boiling fractions had a marked odor resembling that of carvone, but no semicarbazone could be obtained. C. O. EWING.

Hernandia oil. ANON. *Perf. Essent. Oil Record* 6, 264 (1915).—The stem wood of *Hernandia peltata* yielded from 1.03 to 2.06% of a volatile oil having the following characteristics: d₁₅ 0.958 to 0.963, optical rotation +83° 45' to +104° 12', n_D 1.49695 to 1.50111. It contains from 75 to 80% of aldehydes (chiefly dihydrocummic aldehyde) with traces of free acids and a small amt. of esters. The root wood yielded 0.5% of an oil having d. 0.9667, optical rotation +126° 15', n_D 1.50383, and an aldehyde content of 92.5%. The whole fruit gave 0.5% of oil of d. 0.9528, optical rotation +50° 10', n_D 1.49554, and an aldehyde content of 49%. The almond-like seeds gave 1.38% of oil of d. 1.0044, optical rotation +87°, n_D 1.50614, acid value 7.3, and ester value 110.4. The fruit oil did not appear to contain any dihydrocummic aldehyde. C. O. EWING.

Mustard oil and the composition of black mustard seeds. C. A. HUBER AND P. VAN DER WIELEN. *Pharm. Weekblad* No. 39 (1915); through *Perf. Essent. Oil*

Record 6, 341-2(1915).—The amts. of fixed and volatile oil in black mustard seeds from various sources were detd. Dutch, North-Holland, English, Russian, Caucasian, Italian, Sicilian, Rumanian and Bombay mustards contained, resp., 1125, 976, 630, 362, 1690, 910, 964, 490 and 290 seeds per g. wt. In general the smaller seeds, i. e., those having the greatest surface in proportion to their wt., yielded less fixed oil and more volatile oil. The yields of volatile oil were, resp., 1.23, 1.15, 1.07, 0.63, 1.07, 0.87, 0.94, 0.66 and 1.07%. The yields of fixed oil were, resp., 25.7, 28, 31.4, 37.01, 29.8, 32.5, 32.9, 35.7 and 33%. The sp. gr. of the fixed oils varied from 0.919 to 0.923, n_D^{22} 1.4712 to 1.4731, I no. 113.5 to 126 and sapon. no. 182 to 190. Refining produces an oil that is in no way inferior to olive oil for culinary use. C. O. EWING.

Substitute for tamarind pulp. SCHNABEL. *Pharm. Zentralhalle* 56, 416(1915).—As substitute for Pulpa Tamarindorum of the Ger. Pharm. S. recommends the pulp of prunes to which 10% tartaric acid has been added. C. O. EWING.

Cassia pulp as a substitute for tamarind pulp. E. GOLDMANN. *Pharm. Zentralhalle* 56, 496(1915).—G. recommends the pulp of the fruit of *Cassia fistula* as a substitute for tamarind pulp. C. O. EWING.

Extractum Pini silvestris. P. BOHRISCH. Dresden. *Pharm. Zentralhalle* 56, 257-9, 293-9, 313-20(1915).—B. gives comparative tabulated analyses of 4 com. samples, and of 6 samples prepd. by himself from the tips and young twigs of pines (*Pinus silvestris*) and spruces (*Pinus abies*) collected in May. The method of prepn. given in the supplement of the Ger. Pharm. is faulty because the aromatic volatile oil is lost during the evapn. of the aq. ext. This can be remedied by sepg. the oil from the condensed vapors and adding it to the ext. The yield by this procedure is twice as great. The following characteristics are useful in distinguishing between pine and spruce needle exts.: The volatile oil of the pine is levorotatory, that of the spruce dextrorotatory; the Et₂O ext. of pine is dark green, that of spruce light green. The com. exts. gave analyses similar to those of the authentic specimens. The *Extractum Pini silvestris* of the market is prepd. largely from *Pinus abies*. The latter has a stronger and more pleasant aroma. C. O. EWING.

Karl Arnold August Michaelis. R. KOBERT. *Chem. Ztg.* 40, 157(1916).—Died Jan. 31, 1916. An obituary. J. H. MOORE.

Citrate of magnesia in aqueous solution. FRANCINE SWART AND C. BLOMBERG. Amsterdam. *J. pharm. chim.* 12, 387-91(1915); cf. *Pharm. Weekblad* 1908, 1071, 1534; *C. A.* 9, 1973, 2058; and following abstract.—Aq. solns. of this salt, after several days, form an amorphous, white ppt., then a cryst. ppt. of $Mg_3C_2 \cdot 13H_2O$ (Ci = $(C_4H_5O_7)''$), sol. in H_2O (1.8 in 100 at 25°). To avoid pptn., Wijer (1908) doubled the acidity, giving the following formula: Citric acid 25, $MgCO_3$ 10, H_2O 75, simple sirup 25 g. Erkelens uses an excess of citric acid, then a corresponding amt. of $NaHCO_3$. J. Dekker believes that bacterial action is the cause of pptn. and sterilizes the soln. with steam. Bouvet (*Bull. assoc. pharm. de Saône-et-Loire* 1887) also sterilizes at 100°, not to destroy bacteria, but the "germs of crystals of Mg_3C_2 " in the bottle from the air of the pharmacy store. S. and B. confirmed this by a previous expt., having added $HCHO$ to solns. of Mg_3C_2 to destroy bacteria; crystn. nevertheless ensued. As the salt has no bitter taste, the concn. of the Mg ion must be small. It is probably ionized into complex Mg ions: $Mg_3C_2 \rightleftharpoons [Mg_2C]^{+} + [MgC]^{-}$. The slowness of crystn. is due to the moderate speed of ionic reactions with complex ions (cf. *C. A.* 9, 3155). The existence of a readily H_2O -sol. salt with 7.6 H_2O claimed by Léger (*C. A.* 9, 1973) is doubted. The formation of a basic salt Mg_3C_2OH (*Pharm. Weekblad* Sept. 25, 1915) by soln. of MgO in soln. of Mg_3C_2 is explained by means of the ionic theory. S. W.

Reply to Francine Swart and C. Blomberg's article on magnesium citrate in aqueous solution. E. LÉGER. *J. pharm. chim.* 12, 391-4(1915); cf. preceding ab-

The ppt. is digested repeatedly with 65% by vol. alc. until the alk. reaction of the digestion agent disappears, then with a little abs. alc., then with ether, and finally dried at the ordinary temp. The process must be carried out away from daylight, since rapid reduction results from the action of the active rays of the sun. A yellowish brown granular mass is obtained which contains, in 100 parts, from 25 to 30 parts of Hg in colloidal form. The product dissolves readily in H₂O to a clear liquid of a yellow color by transmitted light.

Complex mercury compounds of the safranin series. SACCHARIN-FABRIK AKT.-GES. v. FAHLBERG, LIST & Co. Ger., 286,097, Mar. 10, 1914. Phenosafranin and its homologs are treated with Hg salts. The mercurized safranines are therapeutically applicable.

Lipoid phosphorus-containing compounds from high molecular fatty acid derivatives. F. HOFFMANN-LA ROCHE & Co. Ger., 286,515, Apr. 26, 1914. Addition to 281,801 (C. A. 9, 2292). The hydroxyphosphinic acids, obtained according to the parent process, are esterified according to the usual methods.

Catalytic hydrogenation. C. F. BOEHRINGER & SÖHNE. Brit., 21,883, Nov. 2, 1914. In the hydrogenation of unsatd. substances in the presence of a suboxide of the Ni group as catalyst, the substances are treated in aq. soln. or suspension. In examples in all of which Ni suboxide is used as the catalyst and the substance dissolved in H₂O, dihydroquinine is obtained from quinine-HCl, dihydromorphine from morphine, hydrocinnamylcocaine from cinnamylcocaine, hydrocinnamic acid from cinnamic acid, and ethylenediamine from aminoacetonitrile.

18. ACIDS, ALKALIES, SALTS AND SUNDRIES.

T. LYNTON BRIGGS.

Determination of the yield in the production of nitric acid by the oxidation of ammonia. KARL KAISER. Charlottenburg; BERLIN-ANHALTISCHE MASCHINENBAU AKT.-GES. *Chem. Ztg.* 40, 112(1916).—Disputes as to methods. Cf. C. A. 10, 806. J. H. MOORE.

The nitrate industry. ENRIQUE CUEVAS. *J. Ind. Eng. Chem.* 8, 195(1916).—According to the latest official report of the inspector general of the Chilean nitrate deposits the zone of nitrate-bearing ground comprises 200,000 sq. kilometers of which less than 3% has been surveyed and prospected. In this surveyed area alone there is enough nitrate to supply the world for 100 years measured at the present rate of production. Under present conditions the cost of producing the commercial salt is 50 c. (U. S.) per quintal (104.4 lbs.). H. L. OLIN.

The preparation and commercial uses of hydrogen. ANDRÉ DUBOSC. *Bull. soc. ind. Rouen* 43, 109-14(1915).—The various methods are discussed in the following order: (1) Action of acids on metals, (2) action of steam on metals or other substances, (3) electrolytic processes, (4) diverse methods. MILES R. MOFFATT.

Plastic masses from yeast. H. BLÜCHER. *Chem. Ztg.* 39, 934(1915).—The product sold under the trade name "Ernolith," formerly prepd. from the residues from yeast ext. manuf. (cf. Ger. pat. 275,857, C. A. 9, 361), is now made directly from yeast and HCHO, with the addition of fillers, coloring agents, etc., if desired. The product is dried, powdered and then subjected to hydraulic pressure at 90°; it may be used under certain conditions as a substitute for such materials as galalith, bakelite, resinite, celluloid, etc. The material (free from admixts.) has a dense structure, conchoidal fracture, can be prepd. as hard and brittle or as somewhat soft and elastic, has a d. of 1.33-1.35, is almost non-inflammable, and is carbonized with difficulty. F. W. SMITHER.

The grading industries. EDWARD S. WIARD. *Met. Chem. Eng.* 14, 91-6, 191-7 (1916).—The word "grading" is used in the sense of prep. material according to size or sizes. Various separators and classifiers involving air and water currents are described in detail and the mathematical theory of screens and screening discussed.

H. L. OLIN.

The transport of material in the form of dust. T. C. CLOUD. *J. Soc. Chem. Ind.* 35, 7-8(1916).—A short review and discussion of the methods of dust removal in the industries. A vacuum-producing plant installed for the removal of the As_2O_3 from furnace gases is briefly described.

F. W. SMITHER.

Talc as a lubricant. P. ROHLAND. Stuttgart. *Chem. App.* 3, 6(1916).—Ground very fine it may be used alone or mixed with H_2O or oils. When used with H_2O it must be fine enough to pass through a filter. Cf. *C. A.* 8, 3706.

J. H. MOORE.

The organization of scientific research. J. A. FLEMING. *Electrician* 76, 710-2 (1916).—F. deals with the methods of research, the means of conducting such research and outlines a course of preliminary training.

C. G. F.

Gaging of storage tanks. K. B. HOWELL. New York. *J. Ind. Eng. Chem.* 8, 286-7(1916).—A criticism of the article by Ogden (*C. A.* 10, 668) in which it is shown that the method is not particularly accurate.

F. A. HARVEY.

Action of gaseous ammonia on superphosphate (GERLACH) 15. System lead sulfate-sulfuric acid-water (DONK) 6. Fixation of atmospheric nitrogen (LANDIS) 4. Kimmeridge oil-shales (MANFIELD) 22.

BURR, W. H.: **Elasticity and Resistance of the Materials of Engineering.** 7th ed. New York: Wiley. 928 pp. \$5.50.

Purifying solution containing colloidal silicic acid. H. W. BARON DE STUCKLÉ. *Ger.*, 286,302, Dec. 8, 1912. Cf. *Fr.*, 265,817.

Sulfuric acid. W. S. LANDIS. *U. S.*, 1,173,524, Feb. 29; *Can.*, 165,773, Nov. 2, 1915. An excess of gases containing over 6% of nitrous gases is produced by catalysis of a mixt. of NH_3 and air and combined with SO_2 to form H_2SO_4 .

Titanic oxide concentrate. A. J. ROSSI and L. E. BARTON. *U. S.*, 1,171,542, Feb. 15. Titaniferous iron or ilmenite ores are mixed with sufficient crude Na_2SO_4 and C to insure formation of FeS from most of the Fe in the ore, of Na titanate from the Ti and Na silicate and aluminate from the SiO_2 and Al_2O_3 combined in the gang and this charge is melted in a C-lined elec. furnace. The melt produced, after cooling and crushing, is allowed to stand for 1-2 days to disintegrate and is then boiled with dil. H_2SO_4 in sufficient amt. to dissolve Fe and Na as sulfates and leave a residue containing about 80% or more of Ti_2O_3 (from an ore originally containing about 50%).

Hydrogen sulfide from sulfur dioxide. J. B. GARNER and H. D. CLAYTON. *U. S.*, 1,173,566, Feb. 29. SO_2 is combined with natural or producer gas or other gaseous fuel containing H, in the presence of wood charcoal at a temp. of about 500-600°. Excess H from the fuel gas combines with the S produced, forming H_2S .

Lead arsenate. J. A. SCHAEFFER. *U. S.*, 1,172,741, Feb. 22. A suspension of "fumed" PbO in H_2O is mixed with a soln. of Na arsenate or other sol. arsenate and the mixt. is heated to the b. p. to promote the formation of Pb arsenate.

Binder for silicon carbide. T. B. ALLEN. *U. S.*, 1,172,659, Feb. 22. MgAl silicate (free from any impurities which react with carborundum at high temps.) is vitrified with carborundum to serve as a binder for it. 25% of a ground, sintered reaction product formed from MgO 30, kaolin 55 and flint 15 parts may be molded with

75% of carborundum (with a small amt. of gluten to serve as a temporary binder) and fired at 1400°.

Furnace for calcining aluminium sulfate, etc. H. HOWARD. U. S., 1,173,428, Feb. 29.

Cyanides. NITROGEN PRODUCTS CO. Ger., 286,086, Dec. 15, 1912. Cyanides are obtained from N, C, and an alkali or alk.-earth metal at an elevated temp. Cf. U. S., 1,116,559 (C. A. 9, 129).

Oxidizing aluminium sulfite to aluminium sulfate by means of air. C. A. BERINGER. Ger., 286,366, Apr. 4, 1914. Addition to 269,749 (C. A. 8, 2259). A mixt. of SO₂ and air is allowed to act, under a high pressure and high temp., upon an aluminiferous substance which, at the normal pressure and temp., is only slightly, or not at all, attacked by SO₂.

Compounds of the rare elements. GEBR. SIEMENS & CO. Ger., 286,019, July 17, 1913. Addition to 284,889 (C. A. 10, 100). According to the principal process and addition 286,018, compds. of the rare earth metals, *e. g.*, the double fluorides, are obtained by pptg. dissolved compds. of the rare earths, with others, with fluorspar. The tendency to the formation of the double fluorides is especially great if the solns. contain oxalic acid or other organic acid, which may be contained in the solns. as impurities, or which may be added. The soln., (HOCO)₂, and fluorspar may be mixed at the same time and heated, or the soln. and (HOCO)₂ may be allowed to react upon each other first, and then the fluorspar may be added. The amt. of (HOCO)₂ to be used should be about 5% of the pure content of rare earths. The double fluorides sep. in granular form and may be washed readily. The soln., however, may be heated further, whereby the double fluorides can be converted into the single fluorides of the rare earths. These fluorides have the granular form of the double fluorides, and are no longer amorphous, as are the compds. obtained by the principal process. *E. g.*, 13.5 kg. of pure oxides of the rare earths are dissolved in the least possible excess of HCl or HNO₃ and the soln. is dild. with H₂O to 100 kg. To this soln. is added 1 kg. of a satd. (HOCO)₂ soln. At first a light ppt. is formed which redissolves upon heating. As soon as the soln. boils, 9.6 kg. fluorspar are added and the mass is boiled for 2 hrs. The yield of dry fluoride is 15.6 kg., *i. e.*, 96% of the theoretical yield.

Magnesium chloride. W. S. RAWSON. Brit., 21,261, Oct. 20, 1914. MgCl₂ soln. made by dissolving magnesite in HCl is purified by adding to the concd. and hot, preferably boiling, soln. finely divided MgO, preferably burnt magnesite, until the ppt. no longer increases in d. The ppt. settles readily, and the soln. may be decanted or the whole may be filtered.

Continuous dissolution of potassium chloride. J. SCHNITZLER. Ger., 286,303. May 2, 1914. The continuous dissoln. of KCl and like salts is effected by heating in a stationary vessel, with the introduction of solvent and salt in counter flow.

Dehydrating perborates. DEUTSCHE GOLD- UND SILBER SCHEIDE-ANSTALT V. ROSSLER. Ger., 286,545, Apr. 23, 1914. The crystd. perborates are heated in the presence of liquids which do not dissolve the perborates and which are not oxidized thereby, and which have the property of removing the H₂O which splits off from the perborates upon heating, and preventing it from reuniting therewith. *If, e. g.*, NaBO₃·4H₂O is heated with about twice its wt. of abs. or approximately abs. alc. to 50-70° while stirring, all or a greater part of the crystal H₂O is split off after a short time. After filtering off the alc., a rapidly drying powder of dehydrated NaBO₃ remains. Even the readily oxidizable MeOH is not oxidized thereby, and the loss of H₂O is not attended by a loss of active O. From 500 kg. perborate with a content of 10.37% active O, 327 kg. of a perborate with 15.6% active O are obtained. If the alc. is used again

for dehydrating, a product of less O content, about 12-14% is obtained. The alc., however, can be dehydrated by rectification or by means of lime, to render it suitable for reuse. Instead of alc. certain hydrocarbons may be used such as benzene, toluene, C_6H_5Cl , and the like. Instead of dry crystd. perborates, moist centrifuged perborates may be subjected to this treatment.

Soluble alkali metal silicates. J. W. SPENSLEY and J. W. BATTERSBY. Can., 165,910, Nov. 9, 1915. Anhydrous silicate is ground in the presence of water by means of a hard abrasive material. Cf. C. A. 9, 2972.

Recovery of alkali carbonates. R. BLOM and W. S. NORMELLI. Can., 165,879, Nov. 9, 1915. A process for recovery of alkali carbonates from alkali nitrate obtained by the absorption of nitrous gases in alkali carbonates and simultaneously producing NH_4NO_3 comprizes the steps of absorbing nitrous gases in a soln. of a carbonate of an alkali, transforming the nitrite content of the product obtained thereby into nitrate, reacting upon the resulting nitrate with NH_4Cl to form NH_4NO_3 and an alkali chloride; this chloride is sepd. and reacted upon with $(NH_4)_2CO_3$ to form a carbonate of the alkali.

Continuous production of crystallized ammonium hydrogen carbonate. CHEM. FABRIK BRUGG A.-G. Ger., 286,241, July 4, 1914. The process is dependent upon the continuous production of a warm satd. soln. of NH_4HCO_3 by conducting CO_2 continuously through satd. NH_4OH soln., on the counter-current principle. The satn. is effected in a column containing filling, fed continuously from above with NH_4OH and from below with CO_2 . The column is built up of a series of truncated conical sections, the cross section being larger at the lower end. The lye is cooled in each element in such manner that the temp. of the lye in the column increases towards the bottom, the satd. bicarbonate lye leaving the column at a temp. of 50-60°, whereby no crystn. of the salt takes place in the column.

Making articles from nitrides. E. PODSZUS. Brit., 21,378, Oct. 22, 1914. See Ger., 282,748 (C. A. 9, 2437).

Generating hydrogen. C. ELLIS. U. S., 1,173,417, Feb. 29. A mixt. of CO with 4 to 5 times its volume of H_2O vapor is passed in contact with a counter current of CaO moved by screw conveyers, about 5% of oxide of Mn or Fe being added to the CaO as a catalyst. A reaction temp. of 500-550° is maintained.

Hydrogen. K. SCHAEFFER. U. S., 1,172,908, Feb. 22. Heated Fe is alternately oxidized and reduced by treatment with reducing gas and steam to form H. At the beginning of the operation the Fe is heated with gas and an excess of air and the charge is periodically reheated by passing air through it. The use of an excess of air prevents local superheating and sintering of the charge. Cf. C. A. 10, 98.

Catalyst for synthesis of ammonia. A. MITTASCH. U. S., 1,173,532, Feb. 29. A soln. of K ruthenate and KOH is applied to asbestos, pumice or other carrier and reduced by heating with H and N.

Ammonia. W. S. LANDIS. Can., 165,745, Nov. 2, 1915. A soln. of $Ca(CN)_2$ is heated to a reacting temp., and then the applied heat is decreased and the reaction proceeds under its own evolved heat.

Ammonia from its elements. BADISCHE. Ger., 286,430, Sept. 10, 1911. Addition to 249,447. As specified in the parent patent and its additions (254,437, 258,146, and 262,823), a material increase in the activity of the catalyzers used in the synthesis of NH_3 from its elements results from the presence of various admixts. By the present method, especially good results are obtained by the employment of metal mixts. if these be so chosen that metals or substances are present together, of which the one contains or may take up principally or exclusively H, while the other contains or may take up N. E. g., NH_4 molybdate is gently heated so that a portion of the NH_3 escapes.

The porous granules are satd. with a concd. Pd nitrate soln. (20% Pd nitrate, calcd to the molybdate), then the mass is calcined to decompose the nitrate and reduced with H, or charged directly into the contact furnaces.

Separating gas mixtures. E. ROHLF. Ger., 286,365, Mar. 24, 1914. Lycopodium, when dried *in vacuo*, possesses the property of condensing and combining gases upon its surface and giving them off to surrounding objects. This property of lycopodium is applied in sepg. liquefied gases. The procedure consists in taking up the gas or liquid mixt. by surface condensation on, or satn. by the lycopodium, at the suitable temp., and allowing the gases, by progressive heating, to vaporize in the order of their b. p.

Heat-insulating compositions. BEINDORFF & CO.'S FABRIEK VAN KETEN-BEKLIEDING EN ISOLATIESTOF "ISOLA." Brit., 21,437. Oct. 23, 1914. A heat-insulating compn. consists of preferably 20-60% of wood pulp or like fibrous organic pulp 1-7% of resin, and 15-50% of a mixt. of kieselguhr, and sawdust with or without alum and fillers, such as chalk. The mixt. is molded without pressure. The wood pulp and resin are first finely ground together so as not to destroy the fiber.

Molding with phenol-aldehyde condensation products. E. HEMMING AND HEMMING MFG. CO. Brit., 21,264, Oct. 20, 1914. Mfg. molded bodies with the aid of phenol-aldehyde condensation products. An initial condensation product is prepd. by reaction between a phenolic compd. and a methylene compd., according to any of the known processes, at a temp. below 95°, the reaction being arrested when the product has a sp. gr. between 1.15 and 1.25. This product, which is of a suitable consistency for cold-molding, or which may be brought to this condition by thickening by heat or thinning with a solvent, is mixed with a filler, molded under pressure and at ordinary temp., and hardened by heat after removal from the mold.

Plastic phenol-formaldehyde product. W. T. BONNER. U. S., 1,173,337, Feb. 29. Cellulose acetate is dissolved in a fluid reaction product of PhOH and CH₂O and the mixt. is afterward molded and hardened.

Phenolic resins used in stereotype matrix. G. S. WILLIAMSON. U. S., 1,173,907, Feb. 29. A matrix for stereotype plates is formed of blotting paper impregnated with a sol. silicate and a plastic phenolic condensation product which is rendered infusible by heating.

Adhesive mixture for use with mineral substances. F. TOMPKINS. U. S., 1,171,905, Feb. 15. Spent vegetable tanning liquor is concd. to 48° Tw. and used as a road binder, subsequently, after diln. with H₂O as desired. It may also be used as an adhesive for molders' sand cores, for uniting wood, paper or pasteboard and for other purposes. The concn. facilitates preservation until desired for use.

Elastic material. M. BARRICELLI. Can., 166,177, Nov. 23, 1915. The manuf. of an elastic material by producing an elastic paste of a gelatinous substance, water and glycerol, incorporating in this paste first a quantity of Sb₂O₃, then a quantity of HOAc, maintaining the mass so produced in a molten state until it is to be molded and adding to the same immediately before the molding operation a quantity of a liquid containing formalin and HOAc.

Wire, ribbon, and other articles of molybdenum. CHEM. FABRIK VON HEYDEN. Ger., 286,534, June 20, 1912. The products heretofore obtained from pulverulent Mo and a binder by subsequent ignition *in vacuo* or in a reducing or indifferent gas, had inferior strength and flexibility. Additions of other metals had little effect in correcting this fault. Products which possess the required properties, at both high and low temps., are obtained by adding to the Mo, instead of metals, the oxide of Mg or Ba, or a compd. which upon ignition yields one of these oxides. A suitable mixt. consists, e. g., of 100 parts of Mo powder and 20 parts of MgCO₃. A wire prepd. in this manner, having a

cross-section of 0.17 mm. and a length of 14 cm., supports a load of 1400-1500 g., while a wire made from Mo powder, having the same section and length, supports a load of only 1000-1100 g.

Removing iron from kieselguhr by treatment with acid. VEREINIGTE DEUTSCHE KIESELGURWERKE G. M. B. H. Ger., 286,240, Dec. 9, 1913. By this process a pure white product is said to be obtained, with nearly complete recovery of the acid. The kieselguhr is mixed with acid of about 13° Bé., to a liquid slurry, and this mixt. is heated to about 80°, the freshly mined kieselguhr having been first dried and calcined. About 3 parts by wt. of acid are used to 1 part by wt. of kieselguhr. After heating, the mixt. is cooled and finally pressed into cakes by means of filter presses, whereby the acid is expressed and collected for reuse. The pressed cakes are dried in the usual manner and ignited to remove particles of C. HCl is preferred as the acid.

Nitrogen compounds of silicon and aluminium. O. SERPEK. Can., 166,161, Nov. 23, 1915. Compds. of SiO_2 and Al_2O_3 are subjected with C to the action of a current of N, first at a temp. below 1500° to 1600° to form Si_3N_4 and then at a higher temp. to form AlN.

Separating organic liquids. A. GOLODETZ and B. BENEDIX. Ger., 286,425, Nov. 22, 1911. The process is applicable in the sepn. of constant-boiling liquids and those which contain components with b. p. lying near one another.

Bleaching sand. J. G. A. RHODIN. U. S., 1,173,385, Feb. 29. Sand which is colored by the presence of Fe is bleached by mixing with NaCl soln., drying, roasting and lixiviating the roasted charge.

Artificial lithographic stone. V. H. J. HERENG. U. S., 1,172,796, Feb. 22. See Brit., 5,859 (C. A. 9, 2297).

Dental cement. G. S. MILLER. U. S., 1,172,723, Feb. 22. H_3BO_3 or borax is mixed with powdered washed beryl and Na Al fluoride, the mixt. is satd. with $\text{H}_4\text{P}_2\text{O}_7$ and formed into a thin pasty mixt. with H_2O and heated to obtain a melt which is cooled and powdered and subsequently prepd. for use by the further addition of $\text{H}_4\text{P}_2\text{O}_7$.

Luminous coating. A. JUNGHANS. U. S., 1,173,110, Feb. 22. Luminous coatings such as figures on clock faces are formed by filling recesses in the surface treated with an adhesive and ZnS or other radio-responsive material, coating this material with a layer of adhesive and then with an overlying layer of active material.

Effecting reactions of gases on solids. J. R. C. RUDOLPHS and A. G. THISSELL. U. S., 1,173,390, Feb. 29. In reducing metal oxides with reducing gas, treating CaC_2 with N or removing silicic acid from C mixts. or metal oxides by treatment with F, casings, which may be formed of chamotte, containing a sheet Fe box and a core are filled with the solid charge within the box and around the core and the space between the box and casing is filled with CaO, MgO or other refractory material. The Fe box and core are then removed. A series of such charges is heated in a furnace by combustion gases and then treated with the reaction gas; the porous enclosures prevent deleterious mixt. of the different gases used around and within the casings for heating and subsequently effecting the reduction or other desired reaction.

Gas- and vapor-forming disinfectants and fire extinguishers. R. ZIMMERMANN. Ger., 286,271, June 25, 1914. The preps. are made from aromatic sulfonated diazo compds. which are partially dried on an indifferent surface at a temp. below that of their decompn. and then mixed with an indifferent, non-volatile substance, or they are mixed, while moist with the specified substance, and the mixt. is subsequently dried. The incompletely dried aromatic sulfonated diazo compds. may be mixed with a volatile, indifferent substance which volatilizes when the compds. are decomposed. E. g., 1,4-diazonaphthalenesulfonic acid (with 3% H_2O content) 600 g. is mixed with 400 g.

kieselguhr of like H_2O content, and worked up in the mortar or by rolling, with moderate pressure. The resulting mixt., packed in a box or glass vessel, burns quietly and without flame when kindled with a spark. This prepn. may be obtained more readily by the direct addition of kieselguhr to naphthionic acid, diazotizing, draining, washing, and centrifuging the mixt., and drying it at 45° in small pieces on paper. In this manner may be obtained a very homogeneous mixt. which upon burning loses about 20% in gases and vapors. This prepn., and a similarly prepd. mixt. of 1,4-diazobenzene-sulfonic acid and SiO_2 in equal proportions by wt. of the components, are not only stable but are not affected by friction. They may without danger of decompn. be completely dried on the water bath and rubbed up with the pestle under strong pressure.

19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

The manufacture in France of laboratory glassware. PR. LINDET. *Ann. fals.* 8, 412-4 (1915).—Report of a symposium. H. S. BAILEY.

Effect of temperature on the coefficient of absorption of certain glasses (GIBSON) 2. Toning with cobalt sulfide (NAMIAS) 5.

Glass manufacture. T. J. I. CRAIG and P. SPENCE & SONS. *Brit.*, 21,231, Oct. 20, 1914. The siliceous residues resulting from the treatment of bauxite or other aluminous ores, China-clay, or calcined coal-measure shales with H_2SO_4 for obtaining Al compds. are utilized for the manuf. of glass. The residues are mixed with suitable material such as lime, Ca, etc. Na_2CO_3 to neutralize the acid, and other materials may be added.

Machine for blowing bottles. GLASMASCHINENFABRIK SYSTEM J. WOLF G. M. B. H. *Ger.*, 286,298, Feb. 6, 1914.

Porous composition for use as filtering media. J. E. PORTER. *Brit.*, 22,080. Nov. 5, 1914. Filtering media, of the kind made by fusing together sand and powdered glass, are made by adding a small proportion of infusorial earth to the mixt. before firing. Plates having strata of varying porosity may be made by arranging the sand in layers of different grain. The product resists the action of acids, alkalies and heat, and, in addition to its principal use as a filtering medium for liquids, may be used as a filtering or distributing medium for air and gases as in the dry concn. of ores; in aerating liquids as in the cyanide process of extg. ores and the manuf. of soda and H_2SO_4 as a retainer of liquids, e. g., acetone, in gas cylinders, as a vehicle for catalytic agents in chem. processes, and as a heat insulator.

White enamels. VEREINIGTE CHEM. FABRIKEN LANDAU, KREIDL, HELLER & Co. *Ger.*, 286,038, Oct. 25, 1912. See *Fr.*, 462,587 (*C. A.* 8, 3106).

Clouding agent for manufacturing white enamels. E. HEILMANN. *Ger.*, 285,822. Nov. 24, 1911. The clouding agent consists of a mixt. of MgO and Al_2O_3 or of ZnO and Al_2O_3 , which is so highly heated that spinels are formed or, with an excess of one of the components of the mixt., solid solns. of the spinels with MgO or Al_2O_3 result. The clouding agent may contain, in addition to the solid solns., white refractory materials such as SiO_2 , SnO_2 , ZrO_2 , or TiO_2 , whereby the clouding effect is strengthened. A sufficient addition is 10% of the wt. of the mixed oxides, to obtain a marked increase in the clouding effect. The ignited mixt. may be prepared more cheaply than the SnO_2 used heretofore in larger amts.

Zirconium silicide, zirconium salts, and zirconium oxide. P. JOST and P. PLÖCKER. *Ger.*, 285,981, Feb. 1, 1914. ZrSiO_4 is not attacked, or only slightly by HF or other mineral acids, even upon heating. The sepn. of the SiO_2 from the ZrSiO_4 was effected only by fusing the latter with hydroxides or carbonates of the alkalies at high temps. By the present process a sepn. of the SiO_2 , or at least a decided disintegration of the silicate, can be effected, without the employment of alkalies, by mixing the pulverized material with $1\frac{1}{2}$ times its wt. of coal, and heating this mixt. to whiteness. By this treatment the silicate is reduced to silicide, and CO_2 escapes. By treating the resulting reaction product with dil. mineral acids and filtering from the excess coal, a very pure Zr salt, free from SiO_2 and completely free from alkali, is obtained in soln., from which, by ignition of the sulfate or nitrate, ZrO_2 is obtained. The resulting oxide which, if the ignition is not carried out at too high a temp., contains some basic Zr salt, is especially suited for the production of enamels.

Refractory vessels from the rare earths and from the oxides of thorium and zirconium. O. KNÖFLER & Co. *Ger.*, 285,934, Jan. 22, 1913. The purest obtainable oxides of Th, Zr, and the rare earths, without the addition of binders (by which the m. p. would be lowered), excepting some pure H_2O which is driven off during the process without residue, are shaped by compression in suitable forms under high pressure, whereby the oxides adhere by virtue of their inherent plasticity. Upon subsequent burning in furnaces of known construction, at $1400\text{--}1600^\circ$, the shaped bodies acquire the requisite solidity and hardness. A contraction results from burning, but does not continue upon heating to $1800\text{--}1900^\circ$ and the product does not sinter at this temp. The vessels may be heated to 2000° and above, for a long time, without fusion.

Furnaces for smoking and burning ridge tiles. C. LENGSHOLZ. *Ger.*, 286,294, Nov. 30, 1913.

Tile-cutting device. E. KLÜCKMANN. *Ger.*, 285,860, Jan. 27, 1914. The device is designed for cutting roof tiles before burning.

20. CEMENT AND OTHER BUILDING MATERIALS.

C. N. WILEY.

The role of the chemist in the cement industry. C. N. WILEY. *J. Ind. Eng. Chem.* 8, 276-8(1916).—An address. E. J. C.

The hydration of slaked dolomitic lime. L. KIEPENHEUER. *Tonind.-Ztg.* 39, 696(1915).—Analysis of 4 commercial hydrated limes showed that only the CaO was slaked, the MgO being only partially hydrated. Limes with 26.9% to 37.7% MgO had 6.13% to 21.28% less H_2O than required theoretically for hydration. J. S. L.

Cold weather tests of concrete. ANON. *Cement World* 8, No. 12, 56-8(1915).—Tests on briquets made of standard Ottawa sand with Lehigh Valley cement (2:1) and broken after standing at different temps. for certain times, showed that the lower the temp. at which setting took place, the less the breaking strength. If 5% salt soln. was used instead of H_2O , the briquets were even less strong and did not set as rapidly on standing. R. L. S.

Destruction of concrete by hydrogen sulfide. HEYER. *Chem. Ztg.* 40, 102 (1916).—Analyses are given of samples of damaged concrete from sewers, the cause being traced to H_2S in waste water from a brewery. Cf. Sartori, *C. A.* 10, 377.

J. H. MOORE.

Blast-furnace slag and portland cements. HERMANN PASSOW. *Tonind.-Ztg.* 39, 759-60, 765-6, 771-2, 775-6, 781-2, 792(1915); cf. *C. A.* 9, 1986.—Test pieces made up of 1 part cement to 5 parts sand were observed for 1 yr. in 10% Na_2SO_4 soln. Tests

made with 6 brands of slag cement were volume const. and did not decrease in strength. Tests made with portland cements were disintegrated. Slag cements made up with considerable portland showed bad effects due to portland. Hardening of slag cements is promoted by NaOH set free from Na_2SO_4 by $\text{Ca}(\text{OH})_2$ of portland cement, some slag cements which failed in pure H_2O being sound in Na_2SO_4 soln. All tests kept in 10% MgSO_4 soln. failed in one year except 1 special slag cement. Sea water concd. 5 times had less effect than 10% MgSO_4 or Na_2SO_4 . No slag cements expanded in ordinary sea water and only in a few cases in 5 times concd. water. All portland cements showed effects due to sea water. In use in sea water the life of portland cement depends on the formation of a protecting coating. The use of slag cement in marine work shows a rapid increase. To be most resistant slag cement should be low in CaO and Al_2O_3 .

J. S. LAIRD.

Plaster of Paris from a technical point of view. G. GALLO. *Gazz. chim. ital.* 45, I, 386(1915).—G. comments on the similarity of results obtained by R. Grengg (cf. *C. A.* 9, 1586) to those published by himself (*C. A.* 9, 134) in 1912 to which Grengg failed to refer.

E. J. WITZEMANN.

Zinc chloride as a preservative. ALFRED H. CLARKE. *Wood Preserving* 2, 74 (1915).—C. sought to det. the effect on wood treated with ZnCl_2 of the higher temps. such as are at times found in some parts of factories. Selected loblolly pine sapwood test pieces were impregnated with 4% ZnCl_2 soln. and then subjected to a temp. of 150°F . for 40 days. The av. moisture content of the wood in the treated and control specimens was found to be the same. The treated specimens were found to be more

brittle and showed a modulus of rupture only 83% of that of the controls. Further tests will be made to det. the rate of destructive action, the range of atm. conditions where danger lies and the chem. and botanical factors involved.

E. J. C.

Preservative treatment of fence posts. G. B. MACDONALD. Agr. Expt. Sta., Iowa State College of Agr. and Mech. Arts, *Bull.* 158(1915).—Coal-tar creosote is the most important fence-post preservative. The life of woods commonly used for posts may be doubled by effective creosoting; many species now almost valueless can be made to last 25 years or more. Figuring simple interest at 6%, creosoting reduces the annual cost of the less durable woods by about $\frac{1}{2}$. Detailed instructions are given for treating different species commonly found in Iowa. GEO. M. HUNT.

Water sampling in creosote oil. Report of committee on wood preservation. *Proc. Am. Ry. Eng. Assoc.* 17(1916); *Bull.* 184.—After very careful tests of several methods of sampling for the detn. of water in creosote in a tank car, it is tentatively concluded that for accurate results it is necessary to sample from several zones, giving to each zone a wt. detd. by the relation of the vol. of the zone to the vol. of the car. Cross section sampling is of little value. The best results were obtained with a sampler similar to that shown. Further work is desirable. Cf. *C. A.* 10, 107.

Transport of material in dust form (CLOUD) 18.

DANCASTER, E. A.: *An Elementary Treatise on Limes and Cements*. London: C. Lockwood & Son. 200 pp. 5s.

Cement. A. DENNY and D. G. ANDERSON. Brit., 21,987, Nov. 4, 1914. A quickly setting cement having an alk. reaction is produced by mixing substantially anhydrous gypsum with 1 to 10% of portland cement.

Operation of furnaces for burning lime, cement. AMME, GIESECKE & KONEGEN AKT.-GES. Ger., 286,014, July 6, 1913.

Treatment of woods. R. A. MARR. Can., 165,322, Oct. 5, 1915. A process of treating woods of low sp. gr. consists in impregnating the woods with a mixt. of resin and a melted hydrocarbon material containing a finely divided solid material.

Continuous flooring from bituminous cork masses, especially on concrete. E. MÜLLER and E. EICHERT. Ger., 285,368, Apr. 2, 1914. The cork mass layer is produced *in situ* by stirring granulated cork in molten petroleum pitch, brown coal-tar pitch, coal-tar pitch, or the like, and it is hardened, instead of by compression, by the addition of finely ground, S-containing slags, such as artificial pumice. The liquid cork mass is spread upon the base to a depth of 2-4 cm., and it solidifies by the action of the S slag after 10-15 min. without pressure to a uniform and resistant mass.

Decorative building materials. A. SINDING-LARSEN and R. BOYESEN. Brit., 21,787, Oct. 30, 1914. Friezes, cornices, columns, capitals, panels, etc., are made by lining a mold with stone chippings, broken pieces of stone, glass, etc., and pouring in a backing of cement, gypsum, concrete, etc. The faces of the pieces of stone which are to be exposed are, before being fitted in place, covered with a material capable of preventing the molding material employed from adhering to the exposed face of the finished product. The mold may be lined with a coat of an adhesive such as pitch, paraffin, wax, etc., and the pieces of stone may be then stuck on the mold, which is afterwards filled in with the molding material.

Plaster from calcined lime. F. J. BEHARRIELL. Can., 165,132, Sept. 28, 1915. Process of reducing high-calcium lime to a plaster, by applying to the calcined limestone a certain quantity of H_2SO_4 or dil. HCl.

Artificial stone. C. SCHNEIDER. Ger., 286,423, Jan. 5, 1914. Addition to 285,602 (C. A. 10, 521). The stone is made from cement and comminuted combustible matter.

Brick made from slag. E. R. SUTCLIFFE. U. S., 1,171,676, Feb. 15. Molten slag is granulated in a thick mixt. of $Ca(OH)_2$ and H_2O , drained, dried and compressed.

Artificial stone. P. ROBERT. U. S., 1,172,225, Feb. 15. Clayey earth after heating to dry it is mixed with an equal volume of pine needles, and the heating is continued until the mixt. is dry; crude pine sap is added, the plastic mixt. formed is further heated to drive off the moisture present and the product is molded, *e. g.*, into bricks or sewer pipe.

21. FUELS, GAS, TAR AND COKE.

J. D. PENNOCK.

Scientific utilization of coal. W. A. BONE. *Iron Coal Trades Rev.* 91, 343(1915). --Presidential address read before the chemistry division of the British Assoc.

H. L. OLIN.

The utilization of energy from coal. WILLIAM A. BONE. *Colliery Guardian* 111, 123, 170-1, 220-1(1916); *J. Gas Lighting* 133, 206-8, 253-6, 305-8(1916); *Gas World* 64, 79-81(1916).—A series of lectures reviewing the status of scientific problems relating to the character and uses of coal.

H. L. OLIN.

The microscopic constitution of coal. GEO. HICKLING. *J. Soc. Dyers Colourists* 32, 9-11(1916).—Early attempts at cutting micro-sections of coal showed that in many

cases minute spores of plants are present in great quantities. Their presence was attributed to their original resinous character and it was assumed that the presence of these spores imparted a resinous character to the coal. There is reason to believe, however, that the old theory of coal formation through the successive stages of peat, lignite, etc., is not correct, but that a large portion of the carboniferous vegetation was reduced through decompn. (probably bacterial) to a liquid then absorbed by the undecomposed residues of the vegetation. Recent work separates coals into two dominant types, the bituminous or "humic" and the canneloid or "sapropelic," the latter commonly being the coals rich in spores. There seems to be good reason to believe that anthracite coals may develop from either of these types by some process of alteration. L. A. O.

Boiler economy. C. E. STROMEYER. *Iron Coal Trades Rev.* 91, 447-8(1915).
—A classification and discussion of the various items of cost in steam boiler operation.
H. L. OLIN.

Low-temperature carbonization. ANON. *Iron Coal Trades Rev.* 91, 421(1915).
—The primary object of the new process is to produce from non-coking and semi-coking coals a large volume of light hydrocarbon oils free from tar acids or S compounds, and secondarily, the formation of a residue suitable for conversion into a freely burning smokeless briquet. To accomplish this a small percentage of powdered CaCO_3 is added to the coal. This dissociates at a low temp. in contact with coal high in O_2 and the free CaO liberates the organic bases at low temps.

Smoke as a source of atmospheric pollution. W. F. M. GOSS. *J. Franklin Inst.* 181, 305-38(1916).—A report and discussion based upon investigations made in the city of Chicago during the past 6 yrs. Cf. *C. A.* 9, 2141. F. W. SMITHER.

Peat as a source of fuel oil. W. H. HELM. *Colliery Guardian* 111, 220(1916).
—The oil obtained in the distn. of peat yields on redistn. light oil, fuel oil, paraffin, phenols and pitch. The fuel oil is especially suitable for use in the engines of torpedo boats because of its low S content.
H. L. OLIN.

Simultaneous firing of solid and gaseous fuels. A. DOSCH. *Feuerungstechnik* 4, 1-3, 21-3, 34-7, 42-5(1915).—D. compares in detail the firing of solid and gaseous fuels used independently and when burned simultaneously, particularly with respect to the reactions occurring during combustion and the heat losses from flue gases. The compn. of the final combustion gases varies considerably with the compn. of the gaseous fuel. For the same gaseous fuel, the compn. of the final combustion gases is dependent on the kind of combustion of the solid fuel, i. e., the air excess with which the combustion of the solid fuel results. Most of the article is in the form of equations, tables and curves.
H. R. GUNDLACH.

The use of copper oxide for fractionation combustion of hydrogen and carbon monoxide in gas mixtures. G. A. BURRELL AND G. G. OBERFELL. *J. Ind. Eng. Chem.* 8, 228-31(1916).—A gas analysis app., embodying a CuO tube heated by a small elec. furnace, but containing no new principle, was used for the fractional combustion of H and CO by Jäger's method. The method is more satisfactory than the absorption methods ordinarily employed in detg. CO and H, and its wider use is recommended.
E. A. TSCHUDY.

A new accurate method of gas analysis. O. A. KRONE. *J. Ind. Eng. Chem.* 8, 231-7(1916).—Details are given of the arrangement of app. and of manipulation whereby a complete estn. of CO_2 , illuminants, O_2 , CO, CH_4 , C_2H_6 , H and N may be made in 20 min. The usual method of calcg. corrected results may be greatly simplified.
H. M. LANCASTER.

A suction gas producer using bituminous coal. R. V. FARNHAM. *Colliery Guardian* 111, 165-6(1916).—The essential features of the producer are a rizing and

falling grate and a sliding plate. In firing from the cold, ordinary gas coke is first used with the grate in its lowest position and an incandescent bed is formed. The grate is then raised 10 in. to the level of the slide, this is driven across the fire between the bottom of the fuel bed and the grate and the latter is lowered to its initial position. Bituminous coal is now packed upon the grate, the slide is removed and the hot bed is allowed to settle down upon the fresh fuel. The gas when used in internal-combustion engines leaves no trace of tar in the valves. The coal consumption is 1.74 lbs. per b. h. p.

Burning powdered fuel. H. M. CHANCE. U. S., 1,173,708, Feb. 29. Air is supplied to the burning fuel in intermittent pulsations which agitate and suspend the lighter particles.

Fuel briquets. L. J. CURTMAN. U. S., 1,173,779, Feb. 29. Finely divided coal is molded and baked, with a binder formed of crude molasses 90%, neutralized sirupy concd. sulfite pitch 9% and water-gas tar 1%.

Briqueted fuel. M. ROSSI. U. S., 1,171,660, Feb. 15. Coal, with a binder of tar or pitch, is treated with CS_2 to soften it and is then molded.

Motor spirit. H. GOLDSTEIN. Brit., 21,316, Oct. 21, 1914. A motor spirit consists of a mixt. of 86 vol. of 95% EtOH and 10 vol. of ether, with or without a denaturing agent such as 1 vol. wood spirit and 3 vol. benzole.

Apparatus for supplying air and steam to gas generators. J. M. RUSBY. U. S., 1,172,226, Feb. 15.

Recovering sludge from gas-washers. H. A. BRASSERT and W. MATHESIUS. U. S., 1,171,696, Feb. 15. The wash H_2O from a blast furnace gas washer is discharged into a settling tank from the bottom of which the sludge is removed by gravity, conveyed to the bottom of the skip hoist of the blast furnace and discharged into the furnace.

Gas-washing apparatus. H. A. BRASSERT and C. J. BACON. U. S., 1,172,930. Feb. 22.

Purifying gases. E. L. HALL. Brit., 21,525, Oct. 26, 1914. See U. S., 1,120,475 (C. A. 9, 243).

Nitrogen compounds from air in gas products. O. BENDER. U. S., 1,172,863, Feb. 22. In operating gas producers, some N is oxidized and some fixed as NH_3 by operating under pressure and injecting finely divided H_2O into the fuel. Al_2O_3 is preferably added with the H_2O to increase the fixation of N. When operating with a furnace temp. of 2000° , the gases formed contain 1% NO and 0.25% NH_3 . Cf. C. A. 9, 699.

Producing gas. K. E. BARTH. U. S., 1,172,925, Feb. 22. Vaporized liquid fuel, such as oils or tar, is alternately passed upward and downward, through a body of incandescent solid fuel, to obtain heating or illuminating gas (at about 1000°) or in the production of H (at higher temps.), to secure uniformity of action throughout the charge.

Coal gas. H. L. DOBERRY. U. S., 1,172,682, Feb. 22. Crushed coal is fed from the hopper 5 on to a flowing body of molten Pb 12 which is circulated through a heating chamber (not shown) and the retort 11. The coke produced is skimmed off by paddles on the rotating drum 13 and gas passes off through the pipe 22. A gas of higher heating and lighting value per unit of coal employed is obtained than in the usual distn. in commercial processes, due to the

employment of a uniformly low temp. in distg. the coal. A temp. as low as 425° may be maintained, for effecting complete distn.

Gas producers. S. GLOVER and J. WEST. Brit., 21,517, Oct. 26, 1914. In a gas-producer furnace, the door by which access is obtained beneath the grate is connected to one or more dampers adapted to regulate the area of outflow from the producer, so that when the door is opened for the purpose of clinkering, etc., the area of outflow is correspondingly restricted, to prevent any increase in the flow of air through the furnace.

Discharging retorts. A. M. DUCKHAM. Brit., 21,191, Oct. 19, 1914. A vertical retort is continuously discharged by means of a water-seal trough movable beneath the lower end of the retort and operating in connection with a fixed scraper. The trough may either oscillate to discharge the coke at both sides, or it may reciprocate, in which case one side of the retort is extended to form the scraper.

Coking and gas-generating oven. W. FRICKS. U. S., 1,171,418, Feb. 15.

Removing hard pitch from cooling pans. C. STILL. Ger., 286,243, Oct. 3, 1914. A chain is laid in the pan, and after cooling the mass is broken out by means of this chain.

Fixed coke separator. A. G. GLASGOW. Ger., 286,261, Feb. 5, 1914. The app. is designed to sep. fine coke and slag from the coke mass.

Kimmeridge oil-shales. W. H. MANFIELD. *Engineering* 101, 164-5(1916).—A general review and discussion of the methods of utilization of the oil-shales of the Kimmeridgian series in England and Scotland. The principal English deposits occur in Dorsetshire. In Scotland shales are chiefly mined in Edinburghshire, and Linlithgowshire, the annual output being about 3-4 mil. tons, averaging about 24 gal. of oil per ton. The Tarless Fuel Co. carries out the distn. in a vacuum, using the Tozer retort with internal heating. With the Del Monte retort no vacuum is employed, but internal

heating is effected by burning some of the uncondensable gases in a tube passing through the charge; the retort is inclined at about 15° to the horizontal, and the charge is fed at the lower end, and worked upwards by means of a spiral screw. Except for about 1/3 of its length at the lower end, the retort is heated externally by burning the uncondensable gases with compressed air in jets placed at intervals of about 3 ft. Uncondensable gas is passed in at the top of the retort to drive the vapors down to the cool end, where a considerable part of them, including all the heavy and medium oils, is condensed by the fresh, cold charge, and collected; the remaining vapors are passed through a water-cooled condenser to obtain the lighter oils. It is claimed that this system yields an average of 80 gal. per ton from Kimmeridge shale, and the S content is below 3% (the standard of the Admiralty for fuel oils). M. thinks it would be preferable (instead of the usual process) to pass the crude oil from the Dorset shales through a converter yielding some 20-30% of motor spirit, and to use the residue as fuel oil. In Scotland an average of about 45 lbs. of $(\text{NH}_4)_2\text{SO}_4$ per ton is obtained; shales rich in oil are usually poor in NH_3 , and vice versa. The Dorset shales are rich in NH_3 ; the seam giving the most oil yields 45 lbs. of $(\text{NH}_4)_2\text{SO}_4$ per ton. Many of the shales poorer in oil yield much larger amts. of NH_3 and could be profitably worked by extg. the NH_3 from the vapor without the use of H_2SO_4 by the Burkheiser process, or some modification of it. The removal of S has been the greatest drawback to the shale-oil industry; most of the shales worked contain less than 1% of S, but the shales richest in oil contain the most S, and oil distd. in the ordinary way from the best Kimmeridge shales contains 5 to 8% of S.

F. W. SMITHER.

Lubricating oil for Diesel engines and air compressors. H. MOORE. *Engineer* 120, 176(1915).—The compressors used with Diesel engines have generally been fitted with Cu coils for air cooling, but in some cases these coils have worn thin somewhat rapidly; the thinning occurs from the inside of the tube and mainly round the section of the tube furthest away from the center of the coil, indicating that it is caused by erosion, probably assisted by corrosive action. The greatest care in testing oils for acidity did not prevent a repetition of the corrosion. Investigation showed that under the action of high pressures and temps. some lubricating oils permitted acids to form, which were particularly noted in the drainage from the compressed air vessels. The liquid drained from the receivers was neutral to methyl orange, but strongly acid to phenolphthalein or litmus, and reduced KMnO_4 . Conc'n. by distn. and the extn. of the distillate with ether (after adding NaCl) yielded a small amt. of a strongly acid oily substance, possessing a pungent odor of burnt oil; the "acid" was volatile in steam and appeared to undergo oxidation if exposed to air. M. concludes that this "acid" is a mixt. of org. acids and other O-containing compds. formed by the oxidation of certain constituents of the oil. The formation of such weak acids is considered very briefly from a theoretical viewpoint, from which M. concludes that the I value should provide an indication of the liability of an oil to form acids under compressor conditions. Whether the Cu of the coolers acts as a catalytic agent in the formation of this product has not yet been decided. Tests of numerous oils show that the acid-forming tendencies of oil vary greatly and are certainly to some extent dependent on the I value, though by no means proportional to it. Among petroleum products the I value bears a relationship to the d.: lamp oil (d. 0.807) had I value 5.9-6.5; lubricating oil (d. 0.876) had I value 15.4; heavy fuel oil (d. 0.977) had I value 19.3. The detn. of acid formed was made by titration of the receiver liquor with 0.1 N NaOH and phenolphthalein. The concn. of acid varied from 0.02 to 0.2 N, depending upon the oil, the compressor, and the atm. conditions. The actual wt. of acid cannot be detd. as acidity are not known. No commercial metals were found which are attacked by acid, so that the main point is to prevent the formation

of the acid. Of the ordinary materials tested, mild steel and ordinary brass were the worst and Al the best, Cu and phosphor-bronze coming next to Al. Lubricating oils used in Diesel engines must not only satisfy the requirements of the air compressor, but those of the engine itself. In connection with the latter the conditions are: (a) The oil is exposed to heat from the pistons and cylinders and must not be injured thereby, nor must its viscosity be too much reduced; also it must not give off gases. When testing oils, particular attention should be paid to viscosity and the distn. test at various temps. (b) The oil must be suitable for using over and over again many times without unduly losing its lubricating property. (c) The oil should be capable of being cleaned by filtration and decantation. Oils vary very much in this quality. This property cannot very well be tested in the lab., but should be made the subject of practical tests.

Distinguishing between natural and artificial asphalt. E. GRAEFFE. *Z. angew. Chem.* 29, I, 21-5 (1916).—A review and brief discussion of the various methods reported in the literature, together with a discussion of the formation of natural asphalts and the manuf. of oil asphalt. The following S test is proposed; it is based on the fact that natural asphalts are formed at relatively low temps. for long time periods, and that oil asphalts are produced at higher temps. for short periods, during which the asphaltic action of the S is rapidly effected. Place 1 g. of the asphalt (dried at a low temp. if necessary) in a test tube and stopper with a cork holding a strip of moist Pb(OAc)₂ paper extending to 1 cm. above the sample; heat an oil bath to 200-205° and hold lower portion of test tube in bath for exactly 5 min.; natural asphalts produce a decided blackening of the paper, oil asphalts an inappreciable coloring. Expts. are reported, with photographs of the paper strips showing influence of temp. and time. Mixts. of natural and oil asphalts react like natural asphalt, though in a less marked degree. "Glance pitches" or asphaltites do not give the test; California asphalts (oil) and the residue from Trinidad crude oil react feebly; exts. of asphalt rocks (except Travers) give a faint but distinct test. The pitches show no uniformity in their behavior; wood pitch gives a faint test; the residue from the distn. of the acid resins obtained in the purification of brown coal-tar oils give the test on standing at room temp. The reaction does not depend upon the amt. of S present, but upon how it is bound in the mol. The odor of the various materials as a means of differentiation in experienced hands is briefly touched upon. A table is given showing S content of various natural asphalts, oil asphalts, glance pitches, asphalt rocks, and pitches as detd. by G.'s method (*Z. angew. Chem.* 17, 617 (1904)). Numerous references to the literature are given.

Commercial value (of loblolly pine) for turpentine. CHARLES H. HERTY. N. Carolina Geol. Economic Survey, *Bull.* 24, 53-4 (1915).—When the loblolly pine is wounded it exudes in clear limpid drops fairly large quantities of an oleoresin. Crystn. of the dissolved acids takes place very rapidly; this leads to the rapid evapn. of its content of spirits of turpentine. Crude turpentine from the first 4 weeks' chipping in July contained 17.58% spirits of turpentine; after 4 weeks more the content was 14.11%.

The oleoresin contains only 4.2% unsaponifiable matter. The rosin left on distn. of the spirits of turpentine has an acid no. 172. Cf. C. A. 10, 965. E. H.

Apparatus for distilling mineral oils. A. LACKMAN. U. S., 1,171,524, Feb. 15. The oil is passed successively through a series of stills and preheated by vapors from each still before passing into the next succeeding still.

Separation of hydrocarbon oils. S. W. WHITMORE. Can., 165,359, Oct. 5, 1915. Naphthalene is added to the hydrocarbon and the resultant mixt. is distd.

Separating hydrocarbon oil into its constituents. S. W. WHITMORE. Aust., 7,114, Sept. 23, 1914.

Cracking oils. STANDARD OIL CO. Brit., 21,273, Oct. 20, 1914. In the production of gasoline and other light oils from heavy hydrocarbons by distg. at 650–850° F. under a pressure of 4 atms. or more, the distn. is conducted in the presence of extensive catalytic surfaces, which may consist of plates immersed in the liquid or of plates arranged in the vapor space. With this arrangement about $\frac{1}{3}$ of the charge may be distd. off, the residue constituting an asphalt. The catalytic surfaces may consist of steel, brass, Cu, or other metal in the form of plates or gauze, or of mineral fibers such as asbestos or glass. Cf. 29,862, 1912 (C. A. 8, 2058).

Propagation of flame in mixtures of hydrogen and air. W. A. HAWARD AND T. OTAGAWA. *J. Chem. Soc.* 109, 83–9(1916).—Using tubes of 9, 11.5 and 25 mm. diam., resp., and mixts. of H and air ranging from the lower to the higher limit of inflammability the max. speed of propagation of flame was obtained with 38–45% (by vol.) of H, thus confirming the finding of Mallard and Le Chatelier that the max. speed occurs with higher than the $H_2 + O$ (29.5% H) proportions. M. and Le C. have also stated that on either side of the max. the speeds vary proportionately with the H contents of the mixt. but this is not confirmed by H. and O.'s results, using Wheeler'

CHARLES E. MUNROE.

Protection of cartridges against moisture. O. MERTENS. Düsseldorf. Z. ges. Schiess-Sprengstoffw. 11, 25-6(1916).—The cartridges are made waterproof by grooving the ring between the primer and the case. The air-tightness of the cartridge may be proved by placing a cold cartridge in warm water and noting whether air bubbles appear on the surface, or by placing zinc iodide starch paper in the cartridge and attaching the open end to an air pump and the primer end to a flask in which N_2O_5 is being generated. The paper turns blue if the gas reaches it. O. L. THOMAS.

Measuring the velocity of the detonation for modern explosives. R. FÖRG. Z. ges. Schiess-Sprengstoffw. 11, 17-22(1916). O. L. THOMAS.

West Riding sewage disposal problems. Destructive effluents from explosives works 14.

HILL, W. A.: **Practical Study of the Rough Side of Nitroglycerin as Used in the Oil and Gas Fields.** Tulsa, Okla.: Democrat Printing Co. \$2.00.

Explosives. A. E. VERGÉ. Can., 166,035, Nov. 16, 1915. An initial mixt. of nitrotoluenes containing essentially 45-85% of $m\text{-NO}_2\text{C}_6\text{H}_4\text{Me}$, is nitrated, whereby a liquid $(\text{NO}_2)_2\text{C}_6\text{H}_3\text{Me}$ is produced. $(\text{NO}_2)_2\text{C}_6\text{H}_3\text{Me}$ is dissolved therein, nitroglycerin is added and in this soln. is dissolved nitrocellulose. On oxidizing salt is incorporated in the resulting gelatinous mixt. Cf. C. A. 9, 380, 381.

Explosive. W. C. WADDELL. Can., 165,605, Oct. 19, 1915. A blasting explosive composed of shot-like aggregate of small imperforate rounded units, each such unit being of uniform character and density throughout and the several units being substantially uniform in size.

Hexanitrodiphenylsulfone. C. HARTMANN. Can., 166,160, Nov. 23, 1915. $[(\text{NO}_2)_2\text{C}_6\text{H}_4]_2\text{S}$ is suspended in acid, the mixt. heated and an oxygen carrier is added with stirring.

Blasting. F. ENGELING. Ger., 285,024, July 30, 1913. A safety explosive of high disruptive power is used, with H_2O or other liquid, under pressure, as tamping, whereby a complete utilization of the explosive energy is secured, with up to 75% saving of explosive, while at the same time better mineral samples, and, in coal mining, less coal dust are obtained and the after-damp is decreased. In salt or sylvite mines a satd. soln. of MgCl_2 , end lyes, or the like, is used for tamping.

25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

The dyeing of faded garments. C. M. WHITTAKER. J. Soc. Dyers Colourists 34, 59(1916).—After long exposure the wool fiber of a garment becomes burnt by sun and atm. combined and in many cases it is impossible to redye it any color but black. The problem is one of faded wool fiber rather than faded color. Scoured undyed flannel was exposed to sun and weather for two weeks in August and typical dyes were then dyed upon patterns of the exposed and unexposed flannel. Basic colors dyed the exposed flannel a heavier shade. Direct cotton colors have no fixed rule and show considerable variation. Mordant colors also vary but are not much used in garment dyeing. Some acid dyes are wholly unsuited for garment dyeing but there are others which cover the faded equally as well as the unfaded portion. A strongly acid bath seems to cover the fades better than a weakly acid bath. Indigo does not dye faded wool at all while sulfide blacks dye the faded wool heavier than the unfaded. The experience of the garment dyer shows that an oxidizing treatment is the least remedy.

for cutting up or equallizing fades. Nitric acid works well but cannot be used because it tenders the cotton stitchings and linings. The problem of treating faded garments will probably remain unsolved, because it is due to a definite change in the wool, which gradually approaches complete destruction. Proper selection of dyestuffs in some cases may give satisfactory results with colors other than black, but in most cases only black can be dyed satisfactorily.

L. A. OLNEY.

Observations on garment dyeing. F. E. ROBERTSON. *J. Soc. Dyers Colourists* 32, 44-5 (1916).—It is important that the sp. gr. of the dye bath should be comparatively low; 2° Tw. should not be exceeded. Several advantages are to be gained with H_2SO_4 in the dyeing of acid colors. If the garment has previously been dyed with acid colors they will boil off; stains not removed in cleaning will often be removed in H_2SO_4 bath. Stripping with $Na_2S_2O_4$ is now largely used. Oxidation treatment has the greatest effect in cutting up or equallizing the fades, HNO_3 being recommended when goods will stand it. Colors which exhaust slowly give most level results. L. A. OLNEY.

The multicolored discharge on indigo of diazos combined with vat colors. A. JUTEAU. *Bull. soc. ind. Rouen* 43, 16-7 (1915).—The diazos of nitroanisidine or of naphthylamine mixed with hyposulfite colors and with 240 g. $BaCl_2$ per kg. are printed, then steamed and passed open width through four consecutive vats. The 1st contains 15 g. Na_2CO_3 per l., the 2nd has 10 g. $K_2Cr_2O_7$ per l., the 3rd is a washing tank, the 4th contains 40 g. each of $H_2C_2O_4$ and HCl . In the 1st bath the $BaCl_2$ is changed to $BaCO_3$, in the 2nd the $BaCO_3$ becomes $BaCrO_4$, which in the 4th bath is decomposed with liberation of free chromic acid; this discharges the indigo. A formula is given for the indanthrene color paste.

MILES R. MOFFATT.

Hyposulfite discharge of indigo without steaming. A. JUTEAU. *Bull. soc. ind. Rouen* 43, 14-16 (1915).—A paste is prepd. with 150 g. hyposulfite powder (B. A. S. F.), 30 g. ZnO , and 100 cc. ice water. 100 g. 60° Bé $ZnCl_2$ are added with stirring, and the mixt. is made to 1 kg. with British gum. Print, dry (the drying does not cause decompn. as with hyposulfite), and pad 10-15 seconds in a boiling bath containing 10 cc. 40° $NaOH$ per l., which completes the reduction of the indigo. Then pass through a 2nd bath containing 5 g. Na silicate per l., which removes the leuco-indigo. The advantages of the process are low cost, simplicity, and keeping qualities of the printed cloth. The padding soln. must be renewed frequently, since it becomes strong with hyposulfite which attacks the unprinted portions.

MILES R. MOFFATT.

Preservation by cold of solutions of sodium aluminate. G. A. LEROY. *Compt. rend.* 162, 74-5 (1916).—Two 5-liter flasks were filled with a soln. of Na_2AlO_2 having a sp. gr. of 1.3324 and containing 21.90 g. of Al_2O_3 in 100 cc., and corked. Flask A was allowed to remain at 20°; flask B was kept continuously at -1 to -2°. After 1 month the soln. in A had a sp. gr. of 1.2736, and 100 cc. contained 7.4 g. of Al_2O_3 , while the soln. in the refrigerated flask B had a sp. gr. of 1.3322 and 100 cc. held 21.88 g. of Al_2O_3 . Pptn. began within a day or two in flask A and continued throughout the month.

L. W. RIGGS.

Process of resisting wool against dyeing. A. SAGET. Sealed letters No. 847, 878, and 879. *Bull. soc. ind. Rouen* 43, 21-34; and report on same by A. Juteau, *Ibid* 18-20 (1915).—Sealed letter No. 847. The Meister, Lucius, and Bruning process consists in: (1) Boiling the wool 1 hr. with 25% tannin soln.; (2) a cold treatment in a 15% emetic soln.; (3) 20 min. cold in 3° $SnCl_2$ soln. Saget simplifies this method by omitting the emetic bath, and combining the tin salt and tannin baths, adding oxalic acid to Sn tannate in soln. The following are the proportions he recommends: Tannin ether 10, oxalic acid 1, $SnCl_2$ 1.5, HCl 22%. The goods are entered at 40°, raised slowly to a boil, and boiled 1 hr. The presence of Fe or Cu is injurious. In No. 879 Saget admits that the M. L. & B. 3-bath process gives better results than his

single-bath method, especially if the goods must be given a light alk. treatment before dyeing or fulling. He then returns to a three-bath process, as follows: (1) $\frac{1}{2}$ hr. at boil with 10% SnCl_2 ; (2) 1 hr. at 95–100 in 25% tannin and 2% H_2SO_4 , then rinse, ext.; and (3) treat again at 89–100° in bath No. 1 to which a further addition of 2% of SnCl_2 has been made, and dry.

MILES R. MOFFATT.

Necessity of an American dyestuffs industry to aid export trade in textiles. HENRY HOWARD. *J. Ind. Eng. Chem.* 8, 273–5(1916).—An address. E. J. C.

Analysis of textiles. PONTIO. *Compt. rend.* 162, 81–3(1916).—P. suggests certain modifications of the method of Vetillard. Two solns. are employed: (A) KI 3 g., H_2O 100 g., resublimed I in excess. (B) H_2SO_4 (66° Bé.) 24 g., H_2O 16 g., glycerol (22° Bé.) 16 g. The acid and H_2O are first mixed and cooled, the glycerol is then added and mixed under the cold water tap. This reagent should be made fresh at least monthly. The fiber is boiled in dil. NaOH (2 g. to 100 g. H_2O) for 15 min., the liquid poured off and the treatment repeated. The NaOH is then poured off and the fiber washed until neutral. NaClO (1° Bé.) dild. with 3 vols. of H_2O is then added to the fiber and boiled exactly 2 min., the liquid discarded and the fiber washed thoroughly. It is then treated with NaHSO_3 (5° Bé.) dild. with an equal vol. of H_2O for 5 min. and washed to neutral reaction. The sample thus prepd. is preserved in a tube with H_2O . For the microscopic examn. the sample is dried with blotting or filter paper and placed in contact with soln. (A) for 2 min., then completely dried. Soln. (B) is then added and the cover glass placed. This treatment of fibers does not change their histologic characters. The color changes produced by the action of the reagents are best learned by comparative tests upon fibers of known origin. Also in *Ann. chim. Anal.* 21, 45–9(1916).

L. W. RIGGS.

Causes of damage in bleaching of linen and cotton textiles. J. F. BRIGGS. *J. Soc. Chem. Ind.* 35, 78–80(1916).—Mechanical damage can be detd. by an examn. of the frayed ends of the cut threads, and in some cases by noting the method of weaving, as when a loosely spun weft is combined with a warp of hard-twisted 2-ply yarn. Under the heading *chem. damage*, attention is called to the methods of the modern laundry where the same chemicals are used as in bleaching but with less expert knowledge. Chem. damage during bleaching may result (1) during boiling by the exposure of a portion of the goods above the surface of the boiling liquid; also by crystn. of CaCO_3 in the fiber, a mechanical damage from chem. causes which may be recognized by a microscopic examn. of the fiber. A type of damage which appears in the boiling but is not caused by it, is sometimes observed in fabrics woven from "creamed" linen yarn which has been "overliquored" by the yarn bleacher. (2) Damage by the bleach liquor is the most frequent source of tendering. The tests for the detection of oxycellulose are: reduction of Fehling soln.; formation of a bright yellow ext. on boiling with NaOH, the liquid afterwards turning brownish yellow; and the increased affinity for basic dyes, e. g., methylene blue. These tests will not distinguish oxycellulose caused by overbleaching from hydrocellulose produced by the action of acids. The foregoing tests can only be applied directly to fully purified cellulose; the non-cellulose residues of the fibers after treatment with bleach liquor respond to the tests in much the same way as oxycellulose. General tendering through overliquoring is usually due to a miscalculation of the chem. activity of the later bleach liquors, when the goods no longer have the protective action of a coating of non-cellulose materials. Sharply localized tendering may be caused by the action of metallic impurities, lubricating oils, and unequal immersion in the bleach liquor. Damage in the Na_2O_2 bleaching process is often so complete as to leave little evidence of its cause. The damage may be reproduced by digesting strips which have been spotted with dirty lubrication oil, brass filings suspended in clean oil, ink spots, and aq. solns. of CuSO_4 or FeCl_3 . (3) The

only source of damage by acids is the imperfect washing out of the final sour. A trace of acid left becomes concd. during the process of drying on heated cylinders and causes tendering. This acid may be detected by methyl orange if the goods have not been laundered. Cf. Lester, *C. A.* 10, 119.

L. W. RIGGS.

LUCKIESH, M.: *Color and Its Applications*. New York: D. Van Nostrand Co. 360 pp. \$3.00.

Dyeing apparatus. D. M. HEY. U. S., 1,172,240, Feb. 15.

Yellow dyes. R. SCHÜLE. U. S., 1,172,061, Feb. 15. Tetrazotized diamino-triphenylmethanesulfonic acid is combined with equimol. proportions of an arylmethylpyrazolone and an arylmethylpyrazolonesulfonic acid. The resulting dyes give a greenish yellow or orange-yellow on animal fibers in an acid bath. They are yellow to brown powders, readily sol. in H_2O with a yellow color unchanged by addition of HCl but rendered paler by addition of NaOH.

Brown disazo dye. F. ACKERMANN. U. S., 1,173,077, Feb. 22. A dye of the formula $(HO_3S)(OH)(NH_2)C_{10}H_4.N:N.C_6H_4.NH.CO.NH.C_6H_4.N:N.C_6H_4(OH)_2$ is made by combining tetrazotized 4,4'-diaminodiphenylurea with 2-amino-8-naphthol-6-sulfonic acid and resorcinol. It is a dark brown powder, sol. in H_2O ; it dyes cotton reddish brown which is rendered fast to washing by treatment with CH_3O .

Azo dyes. J. R. GEIGY A.-G. Ger., 286,091, Jan. 3, 1913. See Brit., 30,055 (*C. A.* 9, 1695).

Dyes. Soc. ANON. J. R. GEIGY (formerly ANILINFARBEN UND EXTRACT FABRIKEN, VORM. J. R. GEIGY). Brit., 22,070, Nov. 5, 1914. The monoazo dyes obtained from diazotized 2,3-Cl(NH₂)C₆H₃CO₂H and salicylic or *o*-, *m*-, or *p*-cresotinic acid are heated with solns. of alkalis, whereby the Cl atom is replaced by the OH group. The products are yellow mordant wool dyes and may also be used for calico printing with chrome mordants.

Vat dyes. KALLE & Co. Ger., 286,151, Dec. 21, 1913. α - or β -Naphthoquinone or α -naphthoquinone-2- or β -naphthoquinone-4-sulfonic acid, or their heteronuclear derivs., are condensed with indoxyl or hydroxythionaphthene, their substitution products, homologs, or analogs. The resulting dyes can, furthermore, be acylated, alkylated, or treated with amines.

Vat dyes of the naphthalene series. M. KARDOS. Ger., 286,098, Jan. 10, 1914. Addition to 276,357 (*C. A.* 8, 3243). Instead of the naphthalenedicarboxylic acid imides or the products resulting from the treatment of acenaphthenequinone with hydroxylamine or the substances split off from these, as specified in 276,357, other N-containing derivs. of acenaphthenequinone or its oxidation, reduction, or decompn. products are employed. If necessary, these compds., before or after their conversion into the dyes, may be treated with N-substituting agents.

Vat dyes of the anthracene series. M. KARDOS. Ger., 286,096, Jan. 7, 1914. Addition to 275,220 (*C. A.* 8, 3242). The process of 278,660 (*C. A.* 9, 1997) is modified in that, for the production of N-substituted dyes, the dyes obtained according to 275,220 are treated with alkylizing or aralkylizing agents.

Improving the fastness of wool dyed with vat dyes other than indigo. F. RECHBERG. Ger., 286,340, Dec. 14, 1913. Before dyeing, the wool fiber is treated with chromates or dichromates and an auxiliary mordant such as HCOOH.

Preparations for indigo fermentation vats. FARBW. v. M. L. & B. Ger., 286,338, Mar. 18, 1914. Malt husks are disintegrated by means of alk. reacting agents and thickened. The mass, however, may be preserved by working it up with concd. H_2O .

sol. carbohydrates or their substitutes, and with or without concn. to a sirupy consistence, or drying by evapp. Finally, indigo or indigo white, or indigo white preps., may be incorporated with the preps. obtained in this manner.

N-Anthraquinonylisatins. BAYER & Co. Ger., 282,400, Feb. 27, 1914. Oxalyl chloride is allowed to act on arylaminoanthraquinones, with the addition of condensation agents such as AlCl_3 , FeCl_3 , or P_2O_5 . The resulting isatins form valuable initial material for the manuf. of dyes. Cf. C. A. 9, 2598.

Anthraquinone acridones. BAYER & Co. Ger., 286,095, Mar. 3, 1914. The N-anthraquinonylisatins or anthraquinonylisatinic acids, or their salts, are treated with condensation agents such as AlCl_3 , H_2SO_4 , alkalis, obtaining thereby the acridones, valuable as vat dyes.

Arylidoanthraquinonesulfonic acids. FARBW. v. M. L. & B. Ger., 286,092, Aug. 26, 1913. 1-Amino-2-alkoxyanthraquinones which contain an acid substituent in the *p*-position to the NH_2 group, are brought into reaction with aromatic amines or their sulfonic acids, and the resulting arylido derivs. are sulfonated. Valuable violet dyes with uniform covering power are obtained in this manner.

Color lakes. P. THOMASCHESKI and P. TUST, and SYNTHETIC PATENTS CO., INC. and BAYER & Co. Ger., 286,308, Aug. 5, 1913. Addition to 285,310, U. S. 1,126,664, Jan. 26, 1915. According to 285,310 (addition to 281,422, C. A. 9, 2153), the sulfonic acids of purpurinamide (1-amino-2,4-dihydroxyanthraquinone) are converted into their alumina lakes. The sulfonic acids of 1-amino-4-hydroxyanthraquinone have now been found to yield equally valuable red-violet to violet-blue lakes, and through these the color scale of the lakes specified in the principal patent is extended further towards blue. E. g., Na 1-amino-4-hydroxyanthraquinone-3-sulfonate (obtainable by sulfonating 1-hydroxyanthraquinone, then nitrating and reducing), 1 part, is dissolved in 10-15 parts by wt. of H_2O , boiled with a soln. of 10 parts $\text{Al}_2(\text{SO}_4)_3$ (18% Al_2O_3) in 100 parts H_2O , and then pptd. hot with a soln. of 4 parts calcined soda in 40 parts H_2O . The lake is then prepd. in the usual manner, and yields clear violet coatings of great permanence.

Color lakes. BAYER & Co. Ger., 285,310, Jan. 9, 1913. Addition to 281,422 (C. A. 9, 2153). The principal process is modified in that the purpurinsulfonic acid is substituted by aminopurpurinsulfonic acids. The resulting lakes have a bluer shade than do those of the principal patent. The aminopurpurinsulfonic acids may be obtained from the corresponding purpurinsulfonic acids by treatment with NH_3 ; they dissolve in H_2O with a red color, and in dil. alkali with a red-violet color. The yellow soln. in concd. H_2SO_4 becomes orange in color upon the addition of H_3BO_3 . E. g., 1 kg. Na aminopurpurin sulfonate and 20 kg. $\text{Al}_2(\text{SO}_4)_3$ (18% Al_2O_3) are dissolved in 180 liters of hot H_2O . The filtered soln., while boiling, is mixed with 80 liters of a 10% soda soln., whereby the aminopurpurinsulfonic acid is pptd. as alumina lake with $\text{Al}(\text{OH})_3$. The color lake shows a deep purplish red color, and can be applied as a paste, or dry.

Color lakes from basic coal-tar dyes. BADISCHE. Ger., 286,467, Aug. 9, 1913. Expts. have shown that the basic coal-tar dyes are pptd. by phosphometatungstic acid and its salts in insol. form, and that the resulting ppt. is applicable as a color lake, as it is waterproof, brilliant, and fast to light, greatly excelling in these respects the usual tannin lakes.

Dyeing pelts, hair, feathers. FARBW. v. M. L. & B. Ger., 286,339, May 5, 1914. Aminohydroxynaphthalenes, with *p*-diamines, together with oxidizing agents, are dyed out on mordanted or unmordanted materials.

Dyeing pelts, hair, feathers. CHEM. FABRIK GRIESHEIM-ELKTRON. Ger., 286,337, Apr. 25, 1914. After the preliminary mordanting, the materials are treated with a soln. of *m*-hydroxydiphenylamine with the addition of suitable oxidizing agents.

Preparing vegetable fiber for spinning and weaving. C. MELHARDT. Ger., 286,270, Oct. 1, 1914. The H_2O sol. portion is sepd. from the incrusting substance, with prevention of fermentation, then the vegetable portion sol. in alkali carbonates or like solvents is sepd. from the other constituents. The vegetable fiber is boiled in H_2O until no more soln. is apparent. The product is then boiled for 12–18 hrs. in a soda or potash soln. of about 1%. The residue remaining in the fiber is then entirely removed with soap soln. or the like.

Cellulose products. GLANZFEDEN-AKT.-GES. Ger., 286,297, Aug. 17, 1913. The pptg. bath contains, besides caustic alkalies, $CuCO_3$ which has been formed in the bath itself by the addition of $Cu(OH)_2$ and alkali carbonate. During the spinning the necessary amts. of alkali carbonate are added to the bath from time to time, as the $Cu(OH)_2$ is introduced with the thread, the latter being converted continuously into $CuCO_3$. E. g., $NaOH$ 400 kg. and Na_2CO_3 50 kg. are added to 10,000 liters H_2O . $Cu(OH)_2$, about 50 kg., is then dissolved in the bath. This need be added but once, since during the spinning of the $CuO-NH_3$ -cellulose solns. a certain portion of the $Cu(OH)_2$ goes over into the bath and is converted into $CuCO_3$ by the soda added during spinning. In such a bath a rate of spinning of 45 m. per min. may be secured, in spite of the lower concn. of the $NaOH$. To freshen the baths, a portion of the bath is carried back from time to time, so that always a desired amt. of $CuCO_3$ remains in the principal bath. The portion drawn off is regenerated by evapn., whereby the NH_3 is recovered in the usual manner, and the $CuCO_3$, readily decomposed at a b. temp., seps. as a granular anhydrous salt, without the use of the otherwise necessary reducing agent.

Acetylcellulose filaments. KNOLL & Co. Ger., 286,173, Oct. 10, 1912. In the manuf. of artificial silk thread from acetylcellulose, the difficulty experienced heretofore in unwinding the thread for further spooling, on account of electrification, is overcome by passing the thread, after washing, before or after drying, through a soap bath or a bath of H_2O -sol. oil. In this manner the sep. threads adhere but slightly, and may be unwound easily.

Machine for dressing silk stuffs. E. SCHNEEBELI & Co. Ger., 286,209, Aug. 9, 1912. The freshness, texture, and luster of the material are retained, while the time of treatment is shortened and various treatments are possible.

Loading silk. I. KREIDL. U. S., 1,173,195, Feb. 29. Silk is loaded by dipping in a soln. of a salt of Zr, Yt, Ce or Th, followed by treatment with a phosphate soln. as usual in loading with Sn.

Loading silk. I. KREIDL. U. S., 1,173,196, Feb. 29. Silk is loaded by satg. with a colloidal soln. of Zr hydroxide or other rare earth hydroxide, followed by treatment with Na phosphate.

Apparatus for bleaching yarn. H. R. ANDERS and E. U. SCHÖEDLER. U. S., 1,173,474, Feb. 29.

Apparatus for bleaching yarn. S. BARKER. U. S., 1,173,160, Feb. 29.

26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

The blackness of ink spots on paper. W. MECKLENBURG. Z. *Elektrochem.* 22, 23–7 (1916).—The Schluttig and Neumann method of comparing strips of paper streaked with ink and air-dried is qual. only. "Blackness" is defined as the absorption capacity shown by ink spots under given conditions. M. det. blackness by means of a Tyndall meter (cf. C. A. 8, 2974; 9, 742, 2831). The light passing through a gypsum plate is used as a comparison standard. Ink streaks prepd. according to S. and N., or blots on

filter paper, are placed at an angle of 45° to the axis of the ray and the reflected light is observed in a direction perpendicular to the axis of the ray and in an angle of 45° against the plane of the ink spots. The reflected light is compared by means of a Lummer-Brodhun cube with the light direct from the gypsum plate, the brightness of the comparison ray being reduced by a system of rotary nicols till of same intensity as that reflected from the spots. The angle is read off on a scale and gives a measure of the brightness of the light reflected by the ink spots. Spectral examn. shows that the characteristic "ink black" obtained from an Fe-tannate ink free from dyes is not a dark (deep) neutral gray, but that the green and red rays of the spectrum are more strongly absorbed than the greenish blue. Expts. with ink blots on filter paper show that the relative amt. of the reflected light from the greenish blue is 515μ (the blue field of the spectrum could not be measured with certainty), olive-green 560μ , red 665μ , wave length. Similar, but not identical, results were obtained with strips prepd. according to S. and N. from a commercial Fe-tannate ink after removing dyes with 50% alc. Expts. with the S. and N. and the filter-paper methods showed that the "blackness" of the ink spots diminished very slightly with decreasing amts. of tannin substances and Fe until high dilutions are reached, due to the "hiding power" of a relatively thin layer of the ink "body." It appears possible that although the blackness of the spots from diluted ink is slightly less than that from concd. ink, the permanence of the former follows closely that of the latter. The expts. of S. and N., in which inks made from equal wts. of various components are compared, give no information as to the permanence of the characters or spots from the same inks after different dilutions. Further work is in progress. Tables and curves are given. Cf. Hinrichsen, *C. A.* 1, 783; 2, 1670, 1888; 4, 121, 1550, 1813; 8, 2069; 9, 2155; Kedesdy, 2, 3152.

F. W. SMITHER.

Standard methods of testing varnishes. W. G. SCOTT. *Drugs, Oils and Paints* 31, 249-52(1915), 288-9, 326-7(1916).—For detn. of *viscosity* use the Scott viscosimeter at 70° F., H_2O being used as the standard. Det. *sp. gr.* with Westphal balance or hydrometer. Det. *n* with Abbe refractometer. *Color density*: Compare samples with standard solns. prepd. from solns. of $FeCl_3$, $CoCl_2$ and $CuCl_2$; complete directions are given for this detn. For detn. of *flash point* use open tester. S. states that a chem. analysis is of no value except for the detn. of thinner and the detection of rosin. *Time of drying*: Flow sample on a glass plate and dry at an angle of 60° ; when a minute quantity of fullers' earth is dropped on the surface and none adheres when blown off with the breath, the film is "set free from dust;" when the finger ceases to give an imprint, the film is dry. For examn. for *mixing properties*, any ppt. or cloudiness which occurs on dila. with turpentine or with benzine is noted. *Waterproof qualities*: The effect of water on films of varnish on glass and on varnished panels is noted. *Gas-proof properties*: Freshly varnished panels are dried in a box in which two gas jets are burning. Any cracking or flattening of the film during drying is noted. Working properties, flowing quality, "setting" point and physical defects are noted by panel tests. *Fullness or body*: Directions are given for measuring the thickness of films with a micrometer or by calcn. from the wt. and sp. gr. *Metal plate films*: Sn, Cu or brass plates are coated with Hg and the varnish applied. When dry the film can be stripped from the plate and examd. *Paper film*: Blotting paper is sized with starch and when dry is coated with the varnish. When the film is dry, the paper is soaked in water and the film removed and examd. *Luster, gloss and brilliancy*: Samples are compared with each other or with arbitrarily selected standards. For this comparison, an under coat of dead black is recommended. *Hardness and toughness*: The hardness is roughly measured by laying a piece of duck on the varnished surface and applying a weight. Whether or not a print is made in the film is noted. *Elasticity* is roughly tested by means

of the point of a knife blade. S. condemns accelerated "weathering" tests, made in the lab. For actual weathering tests, he recommends that the varnish be applied to painted steel plates. Directions for painting the plates and carrying out the tests are given.

E. W. BOUGHTON.

Trade intoxications through celluloid varnishes in the aviation industry. F. KORTSCH. *Münch. med. Wochschr.* 62, 1567-9(1915).—The wings, etc., of aeroplanes are varnished with acetylcellulose dissolved in various solvents, among which tetrachloroethane is used. Nine workmen handling such a varnish were taken sick with gastrointestinal symptoms, swelling of the liver and icterus, besides some nervous symptoms such as vertigo or paresthesias. The disease is referable to tetrachloroethane, which is readily absorbed through the skin and by inhalation. Simple masks do not protect against the inhalation of the fumes.

S. AMBERG.

Plastic masses from yeast (BLÜCHER) 18.

Inking rolls. C. NEUBERT. *Ger.*, 286,368, Mar. 5, 1914. The rolls are made of glycerol-gelatin or other colloidal substances, with a coating of rubber. The rubber coating, applied by dipping or spreading, is vulcanized with the usual vulcanizing agents, such as SCl_2 or CS_2 . This rubber coating combines firmly, as a colloid, with the glycerol-gelatin mass, and offers a strong resistance against the pigment diluents used in printing, such as benzene, turpentine, and the like. The rubber surfacing remains smooth and intact.

Etching autotype printing forms. W. J. WILKINSON. *Ger.*, 285,563, May 20, 1913. The plate, prepd. in the usual manner for etching, is first etched flat, then unscreened copy of the original in chromate-glue is transferred to the plate, and the plate is then etched again. By this double etching of the plate a greater contrast is secured.

Pigment etching. A. NEFGEN. *Ger.*, 286,285, Apr. 21, 1914. In pigment etching the interruption of the process and its later completion is often desirable. This is accomplished without difficulty by removing the etching agent with alc., which stops the action of the etching agent without affecting the gelatin film. *E. g.*, the greater portion of the FeCl_3 is rinsed off in a very short time with cold H_2O , and then the pigment layer is washed with dil. and then with concd. alc. The work can then be examined deliberately, treated as desired, and the etching process can be resumed.

Mineral pigments. M. LOEWE. *Ger.*, 285,882, Dec. 31, 1913. Suitable reagents are allowed to act upon the metal compds. of base-exchanging substances. *E. g.*, a K_2CrO_4 soln. is allowed to act upon the Pb compd. of a base-exchanging compd., produced by heating zeolite prepd. by fusion, for 15 mins., with a 10% $\text{Pb}(\text{NO}_3)_2$ soln. and washing out the resulting product. According to the conditions of the expt., *i. e.*, working in the cold or in the heat, and depending upon the Pb content of the base-exchanging compd., a chrome yellow of varying shades is obtained. If a 5% K_4FeCy_6 soln. is allowed to act on the Fe_2O_3 compd. of a base-exchanging compd., a beautiful Prussian blue is obtained.

Pigments. M. LOEWE. *Ger.*, 285,883, Jan. 24, 1914. Addition to preceding pat. Lake-forming org. compds. or their sol. salts are allowed to act on metal compds. of base-exchanging compds. Those bases which are necessary for the formation of the lake are first introduced into the base-exchanging substance. If the org. dye is allowed to act upon these metal compds., the lakes of the particular dyes with the metals are formed. The several bases can be combined with each other, with the production of special shades. For this purpose, the salt solns. of the bases to be combined are mixed in the required proportion, and this mixt. is allowed to act upon the base-exchanging compd., whereby the combined bases are taken up by the base-exchanging compd. in

the desired proportion. *E. g.*, the Al compd. of the base-exchanging substance is obtained by heating an artificial, finely pulverized zeolite, for 30 min., with a 5% $\text{Al}_2(\text{SO}_4)_3$ soln. This is washed out until no trace of $\text{Al}_2(\text{SO}_4)_3$ remains in the filtrate, whereupon it is brought into reaction with a soln. of Na alizarinsulfonate. The resulting red lake is sepd. from the liquid, washed, dried, and slimed.

Pigments. N. W. TURKIN. U. S., 1,173,330, Feb. 29. Color pigments such as Biebrich scarlet are boiled with a mixt. of alizarin oil, basic Al acetate, C_{10}H_8 and fish oil to produce a colloidal soln., which solidifies on cooling, for use in paints, dyes or varnishes.

Flat paint. C. ELLIS. U. S., 1,173,183, Feb. 29. A paint drying with a dull surface is formed of white lead or other pigment and natural linseed oil with a small addition of hydrogenated linseed oil.

Paint- and varnish-remover. J. M. WILSON and C. N. FORREST. U. S., 1,173,628, Feb. 29. A clear soln. of 2.5 oz. of paraffin and a clear soln. of 2.5 oz. of collodion are mixed with CCl_4 1 qt., turpentine or acetone 1 qt. and C_6H_6 2 qts. or with C_6H_6 3 qts.

Paint- and varnish-remover. C. ELLIS. U. S., 1,172,772, Feb. 22. A sirupy finish remover is formed of Na benzoate 5 lbs., dry soap 10 lbs., ceresin wax 25 lbs., celluloid 45 lbs., MeOH 2.5 gals., EtOH 50 gals., C_2Cl_4 40 gals. and $\text{C}_2\text{H}_5\text{Cl}$ 10 gals.

Paint- and varnish-remover. C. ELLIS. U. S., 1,172,773, Feb. 22. C_6H_6 40, MeOH 30, acetone 10, hard paraffin (m. 60° or higher) 0.5-1.0, pyroxylin 3-4, benzyl alc. 8 and pine oil 7 parts are mixed to form a finish remover.

Varnish. E. GIRZIK. Ger., 286,049, May 10, 1913. Train oil and like half-drying oils are used in the manuf. of oil cloth, linoleum, etc. Cf. Fr., 468,003 (C. A. 9, 1398).

Acetylcellulose varnish. L. CLÉMENT and C. RIVIÈRE. U. S., 1,173,931, Feb. 29. A varnish is formed by dissolving acetylcellulose in a mixt. of $\text{C}_2\text{H}_5\text{Cl}$ 90% and amyl alc. 10%.

Surfacing material. F. BURGESS. Can., 165,137, Sept. 28, 1915. A wall or floor surfacing material consists of a layer of varnish, a layer of coarsely ground nut shell embedded therein, a second layer of varnish, a filling layer of finely ground nut shell and a final layer of varnish.

Packaging shellac. B. K. FORD. U. S., 1,173,257, Feb. 29. Orange shellac or similar material is put up in metal receptacles which are lined with Cu to avoid action on the metal.

Coating metals with phenolic resins. W. B. JONES. U. S., 1,171,725, Feb. 15. Articles formed of sheet Fe or other metal are coated with phenolic condensation products with an intermediate layer of linseed-oil varnish between the coating and article to effect a firm union.

Viscose used with phenolic condensation products. J. M. TAYLOR. U. S., 1,172,073, Feb. 15. Viscose produced in the usual manner from 10 parts of cotton or wood pulp is mixed with PhOH 12 and CH_2O 12 parts and the mixt. is heated to obtain a hard dense product somewhat resembling shellac, suitable for the manuf. of molded articles or for use in varnish.

27. FATS, FATTY OILS AND SOAPS.

E. SCHERUBEL.

A study of wool fat. ANDRÉ DUBOSC. *Bull. soc. ind. Rouen* 43, 136-40(1915).—An analysis of the sample, which apparently was Yorkshire grease, is given, with some

exptl. results on purifying the sample with EtOH, 66° H₂SO₄, aq. NaOH, and alc. NaOH. Of all these treatments D. concludes that the one with aq. NaOH is the most practical and economical provided that excessive agitation resulting in emulsification is avoided.

MILES R. MOFFATT.

Completely hydrogenated fats. E. THIELE. *Seifensieder-Ztg.* 43, 26-7(1916).—Two tables are given showing I nos. of 10 completely hydrogenated fats. The figures range from 0 to 1.2.

E. SCHERUBEL.

Catalytic hardening of fats by nickel oxide. W. MEIGEN. Freiburg i/Br. *J. prakt. Chem.* 92, 390-411(1915).—M. defends his former assertion that it is metallic Ni which transfers H to oils and fats instead of some suboxide of Ni as maintained by Erdmann and Bedford (cf. *C. A.* 9, 3136). New expts. are described, some in detail, on the hardening of sesame and soy bean oils at 240-280°, using Ni oxides and at 170-180°, using reduced Ni as catalyzers. Results of tests for metallic Ni, evolution of H, elec. cond. and formation of Ni(CO)₄ are given. *Summary:* (1) Ni oxide is an active catalyst only when free metal is present. (2) Erdmann's objections to M.'s former expts. are based on false assumptions. (3) The presence of free metal in used catalyzers is again proved. (4) Lack of elec. cond. or absence of carbonyl-reaction are not proof of the absence of free Ni, while positive results with these tests always prove its presence. (5) The sp. gr. of catalyzers depends essentially upon org. impurities and proves nothing as regards presence of Ni suboxide. (6) The assertion that suboxide or "suboxide hydride" is formed, is not proved.

P. ESCHER.

A new oil-bearing seed plant. E. M. JASON. *Kew Bull.* 1914, 333; *Chem. Druggist* 1915, 46; *J. pharm. chim.* 13, 26(1916).—The seeds of the South American plant *Osteophloeum platyspermum* Warb. (*Myristica platyspermum* Spruce) yielded to petr. ether 55.2% of a solid white fat of very slight odor; m. 43° f. p. 39°, sapon. no. 240.2, free fatty acids 5.3%, I no. 6.3 n₄₀° (Zeissbutyro-refractometer) 36.9. S. WALDBOTT.

Tobacco-seed oil. N. H. COHEN. *Mededeelingen van het Proefstation voor Vorstenlandsche Tabak* 1915, No. 14, 57-65(1915); *Bull. Agr. Intelligence* 6, 1481.—Tobacco seed contains an oil which is as good as linseed oil for making varnishes. The seed should be collected as soon as the highest leaves have been gathered. About 3 cwt. of seed can be obtained per acre; this would give 1 1/4 cwt. of oil. The oil cake has some value, particularly on account of its N content (av. 4.2%). Some difficulties in collecting and drying the seeds will have to be overcome before their exploitation for oil can be profitable.

E. J. C.

Bean oil (oil from *Phaseolus vulgaris*). FRANZ WITKE. *Chem. Ztg.* 40, 147-8 (1916).—Oil extd. from the last crop with C₆H₆ amounted to about 2% of the dry material, and the acid, sapon., ester, I and Hehner nos. were 17.2, 179.2, 162.0, 97.9, 78.2, resp. The unsapon., P and lecithin were 5.6, 0.98 and 25.6%, resp.; n_D²⁵ = 1.4865. The fatty acids were sepd. and gave for the sapon., I, acetyl no., acetyl acid no., and acetyl sapon. no. 193.1, 124.6, 52.7, 175.4 and 228.1, resp.; n_D³⁸ = 1.4691. Cf. Kosutany, *Landw. Vers. Stat.*, 54, 463(1900); R. Meyer, *Chem. Ztg.* 27, 958(1903).

J. H. MOORE.

Tea-seed oil. J. J. B. DEUSS. *Mededeelingen van het Proefstation voor thee* 1914, No. 33; *Bull. Agr. Intelligence* 6, 1197-8(1915).—The paper deals especially with the oil of seeds of *Thea assamica* (J. W. Master), and *T. sinensis* L. Expts. carried out on a small scale have shown that tea seeds can be successfully exported to London when carefully packed. 43% of oil was obtained by extn. from the seeds dried at 100-105°; if pressure is used the amt. of oil obtained is not increased and there is risk of obtaining saponins in the oil. When absolutely clear the oil contains no saponin. If the seeds become dark brown on drying the oil may be darkened and difficult to purify; other-

wise it is of a golden yellow color. The oils from different species are very similar, are nondrying oils, and possess an agreeable taste. They are used by the Chinese for culinary, medicinal, and toilet purposes. They may also be used in the manuf. of soap and for lubricating purposes as they acidify with difficulty. Tea-seed oil resembles olive and peanut oils in its analytical characteristics. The oil cake after extrn. has no great value, containing only 1.92% N. F. W. SMITHER.

Seed analysis. N. E. KATZ. *J. Ind. Eng. Chem.* 8, 264(1916).—Formulas are given for detg. % of hulls to mix with kernels in order to dil. the cake to desired NH_4 content and also for detg. % of hulls in uncooked and unextrd. meats.

E. SCHERUBEL.

Determination of ricinic acid in oil preparations. F. ERBAN. *Seifenfabrikant* 36, 108-10(1916).—The distribution of the H_2SO_4 consumed during sulfonation and of the alkali used in neutralization is discussed. Less than $\frac{1}{4}$ of the amt. of acid used is combined in the oil. A table is given showing % neutral fat, ricinic acid, diricinic acid, lactide-combined H_2SO_4 and distribution of KOH used for neutralization. Cf. C. A. 9, 1255, 2820; 10, 285.

E. SCHERUBEL.

Note on the saponification value of oils. D. WOODROFFE. *Collegium, London* 1915, 336; *J. Am. Leather Chem. Assoc.* 11, 161(1916).—W. objects to Fahrion's statement (C. A. 9, 1851), that 10 min. boiling with alc. KOH is sufficient, and gives results showing that some oils require longer; he recommends $\frac{1}{2}$ hr. L. B.

Experiments on the catalytic hydrogenation of oil from the French colonies. First series of experiments, "Karité" of French W. Africa and "Aouara" of Guiana. H. HEIM AND A. HEBERT. *Ministère des Colonies, Bull. de l'Office Colonial* [59] 8, 238-44(1915); *Bull. Agr. Intelligence* 6, 1247-8(1915).—Karité (*Butyrospermum parkii*) butter and fat of Aouara nuts mixed with the catalyzer were placed in flasks and pure dry H was passed through at a pressure of 1 to 2 cm. of Hg above atm. pressure. The process was carried out at 50° and also at 180 – 200° for 12 hrs. with const. agitation. As catalyzers reduced Pt in the proportion of 1% and reduced Ni, 5%, were used. At the end of the process the mixt. was dissolved in benzene and the fat obtained by evapn. Results are given in the following table:

Treatment.	Karité butter.		Fat of Aouara nuts.	
	M. p.	I. value.	M. p.	I. value.
Initial.....	32°	65.6	30°	9.5
After hydrogenation with Pt at 50°	35°	57.6	30° – 31°	9.2
After hydrogenation with Pt at 180° – 200°	67° – 68°	16.0	32°	8.1
After hydrogenation with Ni at 50°	34° – 35°	48.0	30° – 31°	9.0
After hydrogenation with Ni at 180° – 200°	69° – 70°	9.6	32°	6.7

F. W. SMITHER.

Low grade fat soaps and remelted soaps. L. B. *Seifensieder-Zig.* 43, 2-3(1916).—Discussion of mfg. process.

E. SCHERUBEL.

Conservation of fats and oils by using fillers in soaps. G. HAUSER. *Seifenfabrikant* 36, 107-8(1916).—Discussion of the use of well-known fillers. E. SCHERUBEL.

Composition of the seeds of *Martynia Louisiana*. E. H. S. BAILEY AND W. S. LONG. *J. Ind. Eng. Chem.* 7, 867-8(1915); see C. A. 9, 2989. E. J. C.

Theoretical considerations on hydrogenation (KORÉVAAR) 2. Lubricating oil for Diesel engines and air compressors (MOORE) 22.

HYDE, F. S.: *Solvents, Oils, Gums, Waxes, and Allied Substances.* London: Constable & Co. 176 pp. 8s, 6d.

Soluble catalyst for hydrogenating oils or fats. N. SULZBERGER. U. S., 1,171,902, Feb. 15. Pd oleate free from protective admixts. which would prevent deposition of Pd at a temp. of 50° is used as a catalyst for hydrogenating oils. It is prepd. by reaction of Na oleate on PdNH₄ chloride and is a yellowish oil, insol. in H₂O, sol. in ether, fats and oils and decomposes on heating or spontaneously on standing, with deposition of Pd.

Catalyst for use in hydrogenating oils. A. SCHWARCMAN. U. S., 1,172,062, Feb. 15. Ni and Al₂O₃ in molecular association are prepd. by adding NaOH soln. to a soln. containing Ni and Al sulfates or other sol. Ni and Al salts, washing and drying the ppt. and reducing it in H. A protective colloid such as wool, hide, hair or glue is preferably dissolved in the NaOH soln. used.

Hydrogenating oils. GEO. CALVERT. Can., 166,053, Nov. 16, 1915. See U. S., 1,142,668 (C. A. 9, 2003).

Extracting oils with chlorinated hydrocarbons as solvents. E. O. BARSTOW. U. S., 1,171,408, Feb. 15. Solvents such as CCl₄, recovered by distn. after use in extg. oils or other substances, are passed upward through a layer of CaO, to neutralize any acid which has been formed in the solvent by decompn. The purified solvent is then used again in the extn.

Oil presses. J. W. PAYNE. Brit., 21,780, Oct. 30, 1914. An oil press is provided with means for alternately raising and lowering the pile of plates, means for charging the top plate in the lower position, and means for retaining the top plate in the upper position, so that the plates are charged one by one and assembled in the upper position, after which pressure is applied for the extn. of the oil.

Powdered soap mixture. S. McCOMB and J. B. McCOMB. U. S., 1,172,297, Feb. 22. A pulverulent detergent is formed of soap 20 lbs., borax 6 lbs., Na₂CO₃ 3.5 lbs., ultramarine blue 8 oz., glycerol 8 oz., and oil of cedar leaves 3 oz. 10 oz. of this mixt. in 4 gals. of hot H₂O is used for brushing carpet or rugs.

A wax-like product from wool fat. J. LIFSCHÜTZ. Ger., 286,245, Jan. 28, 1914. According to 76,613, a considerable part of the wax-like constituents can be extd. from wool fat by fusel oil. The yield, however, is very small (8-10%). Expts. have shown that satisfactory yields of a good wool-fat wax are obtainable by subjecting the crude material, before treatment with solvent, to a partial saponification. The liquid, readily fusible and fatty constituents are attacked first by the alkali, so that not until these are broken up are the higher melting solid substances saponified. If, then, wool fat is saponified, and samples are taken during the process, which are washed with alc. or benzine-alc. in the cold, there is obtained after removing the acid from the undissolved portion a more or less high melting wax product which approaches qualitatively the natural waxes. E. g., wool fat, 100 kg., is saponified with KOH 15 kg. During the saponification tests are taken from time to time and extd. with solvent. The undissolved residue is treated with acid and melted over H₂O. If a test has a wax-like substance of high m. p. and waxy plasticity, the saponification is discontinued, and the whole mass is extd. with alc. or MeOH.

Obtaining a wax mass from wool fat. J. LIFSCHÜTZ. Ger., 286,244, Nov. 26, 1913. The wax is obtained directly from the wool fat. The method depends upon the observation that the soly. of the fatty acids of the wool fat, as such or as alkali soaps, and the soly. of the alc. of the same in alcs. such as wood spirit or EtOH vary, almost uniformly, in inverse proportion to the m. p. of the corresponding fatty acids and the alc., so that lanoceric acid (m. p. 104°), or the alkali salt and solid cholesterol (m. p. 145° and 137°), are practically insol. in 60-70% alc., and oleic acid (m. p. 15°), or its alkali soaps and the soft "cholesterol fraction 2⁰⁰" are most readily sol. If, there-

fore, the saponification or hydrolysis product of wool fat is washed out sufficiently with alc. at the ordinary temp., the readily fusible and liquid constituents go into soln., while the difficultly fusible wax-like constituents remain as a solid cryst. slurry which yields, after removal of the alc. and liberation of the contained acid portion, a bright yellow, wax-like mass m. at 65–68°. This product consists for the most part of the difficultly fusible alcs. and fatty acids of the wool fat. *E. g.*, 1000 kg. crude acid or neutral com. wool fat are saponified, the reaction product is drawn off into a wash vessel, and washed out therein with 60–70% alc. at the ordinary temp. The solid white sludge is mixed with an equal vol. of H₂O which has been mixed with the necessary amt. of mineral acid, and heated to drive off the alc. After a short period of clarification the H₂O is drawn off, and the molten wax mass, after purification on account of color and odor, is collected in shaping vessels. After cooling a light yellow, odorless wax mass is obtained, which resembles carnauba wax in its fracture, but in section, m. p., and plasticity it is very much like beeswax. By employing stronger alc., the m. p. may be raised materially. The yield of wax is claimed to be 35–40% of the crude acid wool fat, and 45–50% of the crude neutral wool fat. The spirituous wash liquor can be worked up into wool fat acids.

28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

The constants of the quartz-wedge saccharimeter and the specific rotation of sucrose. I. The constants for the twenty-six gram normal weight. F. BATES AND R. F. JACKSON. *Bur. Standards. J. Wash. Acad. Sci.* 6, 25–31 (1916).—The purest commercial granulated sugar was purified by repeated recrystn. Two recrystns., removed the ash and reducing power became a minimum. A study of the reaction velocities of the reduction with sucrose and invert sugar showed that a great part, if not all, of this reduction was due to sucrose. By 32 fractional crystns. 5 fractions were obtained which yielded essentially identical rotations. This was considered evidence of the purity of the substance. The rate of decompn. into caramel was detd. at different temps. The sugar was finally dried by a few hrs. heating at 50–60° under 0.001 mm. Hg in the presence of CaO. The sugar was weighed in a volumetric flask. The vol. of soln. was detd. by filling to the mark, and by calcn. from the wt. and d., the latter being taken from tables giving % compn. Each soln. was measured on a polarimeter, and also on 2 of 3 saccharimeters. The calcd. rotation of normal sugar soln. was 40.763°, $\lambda = 5461 \text{ \AA.}$, and 99.89° S, Herzfeld-Schönrock standard. The conversion factor for quartz was calcd. to be 34.620° for $\lambda = 5892.5 \text{ \AA.}$, and 40.690° for $\lambda = 5461 \text{ \AA.}$ For quartz it was detd. that $\phi \lambda = 5892.5 \text{ \AA.} / \phi \lambda = 5461 \text{ \AA.} = 0.85085$; and for sugar, 0.84922. The rotation of the normal soln. was calcd. to be 34.617° at 20°, for $\lambda = 5892.5 \text{ \AA.}$ From 2 values for the rotation of quartz, the thickness of the normal plate was calcd. to be 1.5934 mm. and 1.5940 mm. The calcd. specific rotations for sugar were $[\alpha]_{\lambda=5892.5}^{20.0} = 66.529^\circ$ and $[\alpha]_{\lambda=5471}^{20.0} = 78.342^\circ$. P. M. GINSY.

Comparative action of sucrose and invert sugar on cupropotassic solution. I. MAQUENNE. *Compt. rend.* 162, 145–9 (1916); cf. *C. A.* 10, 980.—Data and curves are given for the reduction of sucrose and invert sugar at different temps. and for different times of heating. The temp. coefficient of the reduction of invert sugar is const. above 70°, and small enough that a variation of 2–3° makes a negligible difference in analytical results, while that of sucrose increases with the temp. This explains the fact that analyses made at the boiling temp. give results which vary with the atm. pressure. With the bath at 65°, the reduction of invert sugar is const. for a time exceeding 15 min.; at 100°, it is const. for above 10 min. The reduction of sucrose in-

creases with the time, and at 65° and 70°, with an amt. of sucrose not exceeding 15 g., it is proportional to the time. From this, M. deduces the following rule: Every sugar 10 g. of which gives in 10 min. at 65° a reduction, the double of which exceeds by one division or more (using the thiosulfate detn. of Cu) that which is obtained under the same conditions in 20 min. heating, contains invert sugar. This method shows the presence of 0.5 mg. of invert sugar with 10 g. sucrose. At 100°, the reduction due to sucrose decreases as the amt. of sucrose increases.

P. M. GIESY.

Determination of reducing sugar by the use of cupro-potassic solutions; different causes of error. H. PELLER. *Ann. chim. anal.* 20, 123-5 (1915); cf. *C. A.* 9, 2463; 10, 538.—By boiling 5 g. sucrose dissolved in 20 cc. H₂O with 40 cc. of Fehling soln., and calcining the Cu₂O, one gets, after 1 min. boiling, 0.020 g. CuO, after 2 min. 0.040 g., after 3 min. 0.060 g. By the new procedure of P. (*C. A.* 8, 1681) one gets 0.004 g. The new procedure is described.

P. M. GIESY.

Experiments on the use of sodium phosphate in white sugar manufacture. P. DE SORNAY. *Bull. soc. chim. de Maurice* 6, 41-4 (1915); *J. Soc. Chem. Ind.* 34, 916.—Laboratory experiments seem to show that using sodium phosphate as a clarifier increases the purity of the treated juice. CaO is reduced 23-34%, going into the scums, and Na displaces K. Practical trials in a Mauritius sugar factory resulted in improved color of the sugar, less incrustation in the evaporators, and more ready boiling than when the ordinary method was used. The sodium phosphate which was used contained 25% H₂PO₄ and 0.1 g. was added per l. of the defecated juice.

P. M. G.

Sugar beets attacked by *Cercospora beticola* sacc. E. SAILLARD. *Compt. rend.* 162, 47-9 (1916).—This year sugar beets were attacked by a mold, *Cercospora beticola* Sacc.; the yield of sugar was poor in quality and quantity, although the sucrose content was nearly the same as usual. The juices were less pure and contained more salts; the alk. juices and sirups lost a large part of their alkalinity during the heating. Analyses given show that the total, amino, ammoniacal, and harmful N was much higher than usual; also that there were present dextrorotatory substances, other than sucrose, which were not pptd. by Pb subacetate in the course of analysis. These substances, like the amino and ammoniacal N, disappear in the course of manuf., so that the molasses contains very little of them, and the rotation is consequently lower.

P. M. GIESY.

Japanese cane. JOHN M. SCOTT. Univ. Florida Agr. Expt. Sta., *Bull.* 129, 44 pp. (1916).—Fertilizer expts. are reported. In addition to the results as to yield of cane it has been shown that the fertilizer does not change the % of sucrose in the juice.

E. J. C.

Continuous sugar-making process. J. NAYLOR, JR. U. S., 1,172,303, Feb. 22. Masseccuite is continuously introduced into a centrifugal separator arranged to discharge continuously sugar and molasses separately. About half the molasses withdrawn is heated to 95° or above and returned immediately to the separator at the same point where the masseccuite is fed, to thin the latter.

Apparatus for bleaching cane juice with sulfur dioxide. L. C. GREVENBERG. U. S., 1,172,133, Feb. 15.

Desugaring molasses and boiling down last runnings. A. GRÄNTZDÖRFFER and A. LIST. Ger., 284,973, Apr. 17, 1910.

Preventing foaming in the scalding process of obtaining sugar sap. E. NEUFELDT. Ger., 285,100, Feb. 28, 1914.

Desugaring starch. DEXTIN AUTOMAT G. M. B. H. Ger., 286,362, June 22, 1914. Starch is treated until it swells, and then mixed with pulverulent starch

moistened with concd. acid. This mixt. is then heated slowly, by indirect heating, to a temp., 105–150°, suitable for the production of dextrin.

Treatment of gums. F. v. RAYMOND. Can., 163,835, Nov. 2, 1915. Process for treating of kauri and like gums by sand blasts, containing sands of different grades or qualities operated by compressed air.

29. LEATHER AND GLUE.

LLOYD BALDERSTON.

Proposed additions to methods. ANON. J. Am. Leather Chem. Assoc. 11, 89–91 (1916).—Standard methods for *dets. of Cr and acid in one-bath Cr liquors* are proposed for adoption as official methods of the Assoc.: for *Cr in leather*, the methods given by Levi and Orthmann (C. A. 8, 3870); for *lactic acid analysis* the methods suggested by 1915 committee (C. A. 9, 1702). A table is given for estg. volatile acid in lactic acid when a specified diln. is distd. in standard app. in a specified manner (p. 96).

L. B.

Guara and its extract analysis. FRED ASHWORTH. London Shoe Trade J.; J. Am. Leather Chem. Assoc. 10, 646–7 (1915); Shoe Leather Rep. 120, No. 6, 53, 57 (1915).—Eitner maintains that guara consists of the ground-up fruits of a variety of *divi minus* the outer husk. Microscopic examn. confirmed this. For other information contained in this article see T. Callan, C. A. 9, 2465.

J. S. ROGERS.

Mangrove cutch in the Federated Malay States. B. H. F. BARNARD. Agr. Bull. of Federated Malay States 3, 241–5 (1915).—The mangrove forests on the coasts of the states of Perak and Selangor embrace 250 sq. miles. The species found in a given region depend on the nature of the soil and the liability to tidal inundation. Nine species are mentioned, belonging to 6 genera. The most valuable of these as a source of tannin is *Ceriops candolleana*, but it is not very abundant. The bark contains 35–40% of tannin. *Rhisophora mucronata* is very abundant, its bark having 30–40% tannin. The other very abundant species is *R. conjugata*; it is poor in tannin. At present the forest is worked entirely for firewood. An acre yields from 4 to 8 tons of bark. No attempt to utilize the bark for the manuf. of ext. for export has been made in the F. M. States.

L. B.

Brazil's tanning materials. ANON. Bull. bur. de renseignements du Brésil à Paris; Hide and Leather 51, No. 7, 28–30 (1916).—Several vegetable tanning products are mentioned. *Barbatimao* (*Stryphnodendron barbatimao* Mart.) is especially good because of its high percentage of tannin; the bark contains from 25 to 48%. Mangrove (*Rhisophora mangle*, L.), known as mangue vermelho, contains no more than 30% tannin, but is very abundant and easy to exploit.

J. S. ROGERS.

The anatomy of *Acacia mollissima*, with special reference to the distribution of tannin. P. A. VAN DER BYL. Union S. Africa Dept. Agr. Sci., Bull. 3, 32 pp. (1914); Expt. Sta. Record 33, 523–4.—The author describes the anatomy of *A. mollissima*, or black wattle, with reference to the location of tannin. This is said to be present in every organ of the plant, but mostly in the phloem region of trees from 6 to 10 yrs. old, young branches and leaves having too low a tannin content to be profitably used.

E. J. C.

Melting point of greases other than paraffin wax (committee report). T. A. FAUST. J. Am. Leather Chem. Assoc. 11, 92–4 (1916).—The Ubbelohde method was not tested, because of inability to get the instruments. A thermometer bulb method, with carefully prescribed conditions, was tested by sending 2 samples to 8 collaborators. The results agree well, and the method is suggested for adoption.

L. B.

Petroleum leather oils. CHARLES R. OBERFELL. *Shoe Leather Reporter* 120, No. 13 (1915); *J. Am. Leather Chem. Assoc.* 11, 2, 74-81 (1916).—Hydrocarbon oils may come from many sources; hence those derived from crude petroleum should be referred to as petroleum hydrocarbon oils. These petroleum hydrocarbon oils do not absorb O nor change in compn. and therefore give best results when used blended with such drying oils as cod or menhaden oils. In this country the supply of petroleum hydrocarbon oils not produced at home comes from Mexico and is obtained from paraffin-base crude and asphaltic-base crude. In distg. crude petroleum at first the fire is applied directly to the still and naphtha, gasoline, kerosene, and another product (which it is hoped may be converted into gasoline) are distd. The distn. of lubricating stock is assisted by direct superheated steam. At this point, oils suitable for use on leather are produced. They are cleaned and bleached by treatment first with H_2SO_4 and then with caustic lye, after which they are washed with hot water until clean and neutral, and then sepd. from the water. The oil may be passed through a bone charcoal or fullers' earth filter to improve the color further if desired. The oil may be chilled and pressed. In some cases it is placed in shallow tanks and subjected to the bleaching and mellowing action of the sun's rays and atmosphere. 'Sp. gr., viscosity, emulsification, evapn., acidity or alkalinity, flash and fire point (to a less degree), and cold test are the characteristics which should be taken into account for the valuation of petroleum hydrocarbon oils. The gravity is measured with a Westphal balance or by a hydrometer. It is usually given in Baumé degrees. Oils suitable for leather weigh about 7.25 to 7.75 lbs. per gal. The viscosity may be measured by the Engler app. An oil of proper body flows well when worked, sticks to the whole leather surface, and eventually penetrates where it remains to lubricate. The emulsifying property is of great importance. After leather has been oiled off and hung to dry, the grain side is given a coat of oil to force the water to evap. from the flesh side. This protective coat of oil does its work better if emulsified. Filtering retards, while exposure to the sun facilitates, emulsification. Tanners often blend animal or vegetable oils with petroleum oils to make them emulsify. The ease of formation and not the duration of emulsification is important. A simple test is to emulsify oil and a few drops of water in the palm of the hand. Oils may be robbed of "greasiness" for leather at the filter presses by too much chilling, so the cold test may be of value. When heated 15 hrs. at 212° F., the loss with Northern oils should be less than 1%, with Southern oils less than 5%. Too high volatile content causes a harsh feel and cut both in grain and fibers. The oil should be neutral. Flash and fire tests are of value only in connection with the cold test and sp. gr.

J. S. ROGERS.

Leather dressing notes. "HEMATINE." *Shoe Leather Reporter* 121, No. 3, 27-31 (1916).—Flexibility and waterproofing qualities as well as gain in wt. are aimed at by *stuffing with degreas*. Two parallel series of expts. showed that leather tanned to just the proper limit gained 15% on the wt. of the dry leather by the grease absorbed, while overtanned leather gained only 5% and was darker. Empty leather absorbs more than a full one. Puered skins absorb more degreas than skins which have been tanned without, but the gain is more than balanced by the leather substance lost in the fermentation processes in the puer and in drying. A good *fat liquor* is made by mixing 2% degreas and 1% fish oil, then 1.5% best white soap in a strong soln. After the fat-liquoring, the grain side is degreased by brushing over with a soln. 3% borax, 2% good white soap and 95% water. The skins are then rinsed in warm soft water and dried, sometimes sponged with linseed mucilage and dried, in prepn. for dyeing. If dyeing precedes fat-liquoring, H_2SO_4 may be used in the dye bath. A lot of dye-stuff is removed, however, in the subsequent fat-liquoring. Soft water should be used on hides after unhairing and before fleshing to prevent lime blast. *Valonia* carries more than one tannin. When a fresh valonia liquor is allowed to stand, decompn.

takes place and one of the products is bloom. This imparts wt. and firmness if deposited on hide; consequently valonia is used as a dusting material for sole leathers. After all the bloom is deposited, the liquor is much less astringent and may be used for producing a mellow tannage for dressing leather.

J. S. ROGERS.

Waterproofing leather. M. SZAMATOLSKI. U. S., 1,173,988, Feb. 29. Chrome leather shoe soles are waterproofed and given a firmer texture by treatment with a mixt. of rosin 5, naphtha 5 and paraffin oil 1 part.

Tanning. G. DURIO. U. S., 1,173,182, Feb. 29. Hides are cleaned and washed and when free from washing liquor they are treated on both sides with commercial, undiluted liquid tanning ext. which is brushed on or allowed to flow over the hides. The excess is continuously drawn off. Tanning is completed in 2-20 days, according to the thickness of the skins or hides.

Preparing hides and skins for tanning. E. D'HUART. U. S., 1,170,426, Feb. 1. The hair is removed from the skins by treatment with $\text{Ca}(\text{OH})_2$ or a concd. $\text{Ba}(\text{OH})_2$ or $\text{Sr}(\text{OH})_2$ soln. and the skin is then treated with a soln. of Na, K or NH_4 glycerophosphate and free glycerophosphoric acid and afterward with the free acid alone to plump the hide. An alkali hydrogen carbonate, NH_4NO_3 or an NH_4 fatty acid salt may be added to keep the hide soft and pliable.

Permanent aqueous solutions of albumin and gluten substances. C. BEYER. Ger., 286,099, May 3, 1914. The object of the process is so to treat glue and albuminous substances, without affecting their adhesive properties, that they dissolve promptly in H_2O and that the resulting solns. neither gelatinize in the cold nor coagulate upon heating. This is accomplished by mixing glue, casein, or albumin with at least 10% of its wt. of resorcinol and heating the dry mixt. for some time under pressure in the autoclave. An extractive brown mass is thus obtained, which may be dild. readily with hot H_2O , and can be used as an adhesive and varnish. Upon cooling the aq. soln., small amts. of a resorcinol compd. sep., which upon the addition of some alc. redissolve promptly. The solns., clarified with alc., are neutral, possess strong adhesive properties, are quite permanent, do not gelatinize in the cold, and upon boiling do not deposit a sediment. Animal glue may in this manner be easily converted, with resorcinol, into permanent liquid glue. E. g., dry casein 50 kg. is mixed with resorcinol 10 kg., and this mixt. is heated in the autoclave, under 3-4 atms., for 3 hrs. After this time the mixt. has become a brown thick ext., and this is dissolved in 100 kg. of hot H_2O . After cooling, it is cleared by stirring in 5 liters of alc.

30. RUBBER AND ALLIED SUBSTANCES.

R. T. STOKES.

Vulcanization experiments on plantation Para rubber. The cause of variability. B. J. EATON AND J. GRANTHAM. *Agr. Bull. Fed. Malay States* 3, 175-203, 397-401, 442-5 (1915); abstracted in part under above title in *C. A.* 10, 400, which see.—Further expts. were made to det. the effect of each operation in the prepn. of thin crepe on the lengthening of the optimum time of cure in the finished rubber, and to det. how far uniformity is possible under ordinary estate conditions. It was found that the effect of each stage in the prepn. of a thin crepe is to retard the cure; but when this retardation reaches a limit, a very uniform rubber is obtained. The cure is slow, and the mechanical tests are slightly low. The results of tests on 10 samples from 1 estate, 1 sample being collected each day for 10 days, showed a high degree of uniformity in the case of eight of the samples. The other two differed slightly, no formalin having been added to the latex. To produce uniform results, however, the conditions must

be kept absolutely rigid; even the tapping conditions must invariably be the same. Furthermore, if the rubber is creped the same day that it is coagulated, as is necessary when uniformity is desired, the resulting rubber is slow in curing and slightly weaker. The effect of the various stages in the prepn. of the block form of plantation rubber was then detd. These stages are: Slabbing from coagulating pan, thick crepe, thin crepe, wormed rubber and rubber dried for 1 to 8 hrs. in hot-air driers. Rubber in the first stage cured most rapidly, and samples from each succeeding stage required more time for cure than the sample preceding it, the time necessary for cure varying from $1\frac{1}{2}$ hrs. in the case of the first sample to $3\frac{1}{4}$ hrs. for the last. All of the samples dried in hot air showed a diminution of the breaking load. Finally it was found that if the rubber was left in the form of a slab, and allowed to "mature" for a week before conversion into block form, a rapidly curing rubber with good mechanical properties was obtained.

R. T. STOKES.

Vulcanization experiments on plantation rubber. The extent of variability caused by lack of uniformity in factory methods. I. B. J. EATON AND J. GRANTHAM. *Agr. Bull. Fed. Malay States* 3, 218-25(1915).—Expts. were made to det. the following: (a) the effect of creping, (b) the effect of maceration, (c) the effect of creping on the load-stretch curves, not detd. in (a), (d) the effect of adding excessive acid in coagulating, (e) the effect of adding NaHSO_3 to the latex to prepare pale rubber. The following conclusions were drawn: The effect of creping on rubber is negligible, both as regards optimum mechanical properties and rate of cure, unless the creping is excessive. The slight effect of retarding the rate of cure in excessively worked rubbers is probably due to removal of traces of a catalytic substance or something necessary to its formation, i. e., to overwashing rather than overworking. The effect of adding an excess of acetic acid to coagulate the latex has a marked effect in retarding the rate of cure, but the mechanical properties are not affected. The acid probably reduces the amount of the catalytic substance finally present in the dry rubber. The effect of bisulfite on crepe rubbers is nil, although there is reason to believe that the use of this chemical in the prepn. of sheet and other forms of rubber is harmful, if it is not afterwards completely removed.

R. T. STOKES.

Vulcanization and testing of rubber. B. J. EATON. *Agr. Bull. Fed. Malay States* 3, 230-6(1915).—A loose series of notes and criticisms relating to work on vulcanization. The absence of a central organization for the coördination of rubber research, or rather the failure of the existing (or possibly defunct) International Rubber Testing Committee is deplored. E. thinks that the fault lies in the fact that until recently such work was in the hands of private consulting chemists, who could not be expected to give their results to the public; or that many valuable researches have been carried out by chemists in the employ of large corporations for the benefit of their employers alone. To emphasize his contention that vulcanization research must be carried out on satisfactory lines, E. criticizes the results obtained by Fol of the Netherlands Rubber Testing Station, published in a paper presented to the International Rubber Congress held in Batavia in 1914. Fol's tests on 137 samples of plantation Para are of no value because he neglected to take into account their variable vulcanizing capacity. Fol vulcanized all samples with the same percentage of S under the same conditions of heat and pressure. He particularly neglected to observe that the greater the proportion of some particular catalyst, derived from the latex and present in the raw rubber, the more rapid the combination of rubber and S. In E.'s work (see *above*) the proportion of S and the temperature have been kept const., but the period required by the nature of the rubber. Earlier conclusions on the proportions of combined S and E. have based their conclusions on the

mechanical test. There is obviously some relationship between combined S and the mechanical properties of a compound, but whether the amount of combined S at the correct cure is more or less a constant remains to be investigated. R. T. STOKES.

The nitrogen content of rubber and its relation to the rate of vulcanization. J. GRANTHAM. *Agr. Bull. Fed. Malay States* 4, 1-4(1915).—N detns. were made on a series of both smoked and unsmoked plantation rubbers in both slab and sheet form, before vulcanization. The % of N and the optimum time of vulcanization for the various grades were as follows: smoked sheet 0.445%, 3 hrs.; creped smoked sheet, 0.441%, 3 hrs.; smoked slab after creping, 0.451%, $1\frac{3}{4}$ hrs.; unsmoked sheet, 0.423%, $2\frac{3}{4}$ hrs.; unsmoked sheet after creping, 0.434%, $2\frac{3}{4}$ hrs.; unsmoked slab after creping, 0.321%, $1\frac{1}{4}$ hrs. No relation can be traced between the N content and rate of vulcanization in the smoked rubber. The unsmoked rubbers, on the other hand, show a regularly increasing % of N with a decreasing rapidity of vulcanization. The loss of N in the unsmoked rubber is probably due to decompn. of the protein, with which the rapidity of vulcanization appears to be associated. Smoking tends to fix the N, but does not prevent a slab rubber from curing at a rapid rate; hence it cannot be the actual loss of N which produces rapid vulcanization. The low % of N in rubber prep'd. from wet unsmoked slab is attributed partly to loss as gas during the superficial drying of the slab, and partly to the washing out of nitrogenous products when the slab is creped. R. T. STOKES.

Vulcanization experiments. B. J. EATON. *Agr. Bull. Fed. Malay States* 4, 4-6(1915).—From latex containing approx. $1\frac{1}{2}$ lbs. dry rubber per gallon, coagulated by the addition of 3 oz. of a 5% soln. of acetic acid per gal. of latex, 2 sets of samples were prep'd., one in the form of a slab and the other in the form of crepe. The slabs were allowed to stand after coagulation for the period necessary for the changes to take place to produce a rapidly curing rubber (6-9 days). The creped samples were machined a few hrs. after coagulation to produce a slowly curing rubber. Batches of varying proportions of these 2 samples were then made up with 10% S and vulcanized the optimum periods. Batch A (rapidly vulcanizing rubber) required $1\frac{1}{2}$ hrs.; Batch E (slowly vulcanizing rubber) $3\frac{1}{2}$ hrs.; B (2 of A plus 1 of E) $1\frac{3}{4}$ hrs.; C (1 of A plus 1 of E) $2\frac{1}{4}$ hrs.; D (1 of A plus 2 of E) $2\frac{3}{4}$ hrs. These results show a gradation in rate of cure according to the proportion of fast or slowly curing rubbers in the mixt. This expt. satisfies E. as to the cause of the variability of the cure of plantation rubber, which is so objectionable to the rubber manufacturer. Fine hard Para is a constant curing rubber because a biscuit consists of latex collected on different days for a period of several months, so that any variation in the latex or in the method of prep'n. is averaged, with the result that 1 biscuit is very similar to any other. The uniformity is due to averaging. The expt. indicates a method which could be used on rubber estates, if, as is often the case, the rubber prepared on different days varies considerably in rate of cure and behavior on vulcanization. The chief disadvantage would be in sampling and testing, for the reason that if a box of sheets made on different dates were sampled by testing 1 or 2 sheets only, the results would not represent the entire bulk. The only satisfactory test would be to mix the whole before sampling. Schidrowitz has suggested the testing of $\frac{1}{4}$ -ton lots, but it is the opinion of E. that even this quantity is not properly representative of the bulk of rubber from even 1 estate, especially in the case of sheet rubber. Much preliminary investigating is required of a large number of samples from the estate. Each estate should carry out a series of tests on samples from each shipment, to see what the actual variation is likely to be, before the inauguration of such a scheme. The preference of certain manufacturers for the rubber from certain estates is probably due to the knowledge that the rubber from these estates is always uniform. The method of bulking latex, and the greater control of dñl. of latex and

amt. of coagulant, and subsequent treatment in estate factories have tended to much greater uniformity than was the case a few years ago. On any particular estate the rubber prepd. at different times is probably very uniform, but the great differences existing between rubbers from various estates still justify the manufacturers' complaints on the lack of uniformity of plantation Para rubber. R. T. STOKES.

Coagulation of Hevea latex. B. J. EATON AND J. GRANTHAM. *Agr. Bull. Fed. Malay States* 4, 26-30(1915).—E. and G. oppose the theory brought forward by Whitby (Proceedings of the Congress of Applied Chemistry, 1912) (*C. A.* 7, 2318) that natural coagulation of Hevea latex is caused by a coagulating enzyme, and advance a bacterial theory of natural coagulation. It was found that the coagulation is due to certain bacteria which infect the latex after collection. Of these organisms there are 2 kinds, 1 favored by anaerobic conditions which effects the coagulation of the latex, and 1 favored by aerobic conditions which tends to inhibit coagulation and produces an alk. slime in the presence of air. The coagulation of latex under anaerobic conditions is not const., being much less complete on some days than on others, possibly because of a variation in the constituents of the latex. By the addition of various sugars, coagulation under both aerobic and anaerobic conditions always occurs, and is caused by the fact that a medium is formed more favorable for the organisms which produce coagulation and less favorable for the organisms producing putrefactive changes. R. T. S.

A new rapidly vulcanizing rubber. B. J. EATON. *Agr. Bull. Fed. Malay States* 4, 30-3 (1915).—An excess of acetic acid used in coagulation retards the rate of cure (see *supra*). It was thought that this excess of acid inhibited the action of microorganisms which are thought to produce the substance accelerating the rate of vulcanization. Expts. were therefore carried out in which the excess of acid was neutralized, and an alk. medium formed by immersing slab rubber in 1% solns. of NaOH and Na_2CO_3 . Lime water was tried and found unsatisfactory. The slabs were soaked in the alkali for 18-24 hrs., removed from the solns. and left on racks for about 10 days, after which they were converted to thin crepe and dried. The following results were obtained: Sample E (soaked in NaOH soln.) showed optimum time of cure of $\frac{1}{2}$ hr., breaking load 1.43 kg. per sq. mm., elongation at break 940%; sample F (soaked in Na_2CO_3 soln.) cure $\frac{3}{4}$ hr., breaking load 1.44, elongation at break 970%; sample H (control) cure $1\frac{1}{4}$ hrs., breaking load 1.51, elongation at break 966%. Further tests showed sample E to be absolutely overcured at 1 hr., and sample F at $1\frac{1}{2}$ hrs., while sample H did not become badly overcured under $1\frac{3}{4}$ hrs. Sheet and crepe ought to cure more rapidly under these conditions also, although not as rapidly as slab. Whether the effect produced by these alkalies is a direct chemical action or is due to the formation of an alk. medium more favorable to biological processes remains to be detd. R. T. STOKES.

Vulcanization experiments on plantation rubber. B. J. EATON AND J. GRANTHAM. *Agr. Bull. Fed. Malay States* 4, 58-62(1915).—In an earlier expt. it was found that a slowly curing plantation rubber could be converted into a rapidly curing rubber with superior physical qualities by allowing the coagulum to stand for about 10 days before it undergoes the usual procedure for conversion into block form. Further expts. show that the change causing this phenomenon takes place in the first 3 days, after which little or no further change takes place under ordinary circumstances. After the rubber has been slabbed, the amt. of substance causing the acceleration of the rate of cure does not apparently decrease with increasing age of the rubber. R. T. STOKES.

Preparation of rubber samples. J. H. LINK. *Chem. Analyst* 1915, No. 15, 7.—For rubber of high quality, cutting is preferable to grinding. An "Enterprise" food masticator is recommended for the purpose. H. M. LANCASTER.

Rapid electrolytic method for total lead and zinc in rubber compounds. E. D. DONALDSON. *Chem. Analyst*. 1915, No. 15, 11-12.—Digest the ash in HNO_3 , ppt. Pb

electrolytically as PbO_2 , evap. and ppt. Zn as metal. Both detns. are electrolytic, the circuit including a 110 v. d. c. generator, lamp rheostat and pole-reversing switch. Electrodes are of sand-blasted Pt gauze, a larger one, diam. 1.5 in., height 2 in., and a rotating gauze, diam. 0.5 in., height 2 in. Weigh 1 g. rubber, wrap in 7 cm. ashless paper, and ash in a 25-30 cc. porcelain crucible. Cool, brush the ash into a 200 cc. electrolytic beaker, add 25 cc. concd. HNO_3 , digest on the hot plate for 15 min., boil to expel oxides of N and dil. to about 125 cc. Electrolyze at 70-80° with rotating cathode, using 2-3 amp. for 30 min. Wash the anode first with H_2O to remove mechanical impurities, and then with alc. and Et_2O . Dry 30 min. at 170°, weigh as PbO_2 and calc. to PbO . Other metals do not interfere. Wash the soln. and insol. matter into a 1000 cc. beaker, add 5 cc. concd. H_2SO_4 , evap. to dryness and drive off the greater part of H_2SO_4 , to insure removal of HNO_3 . Cool, digest residue with 50-75 cc. H_2O , filter and wash. If Zn is known to be low in amt., use whole soln., but if 20% or more of Zn is present dil. to 200 cc. and use 50 cc. Wash this aliquot into a 200 cc. electrolytic beaker, add NaOH in satd. soln. until ppt. of $\text{Zn}(\text{OH})_2$ is redissolved, and then a considerable excess. Electrolyze at room temp., with 2-2.5 amp., using the rotating anode, for 20 min. Remove anode, wash with H_2O , alc. and Et_2O , dry at 100 for a few min., cool and weigh. Al does not interfere, even if $\text{Al}(\text{OH})_3$ is present. If Fe is present, filter off the $\text{Fe}(\text{OH})_3$ before the excess of NaOH is added, then add NaOH to the filtrate. To remove PbO_2 and Zn from the Pt gauze, use concd. HNO_3 satd. with $\text{H}_2\text{C}_4\text{H}_4\text{O}_6$.

H. M. LANCASTER.

The determination of sulfur in rubber. E. L. DAVIES. *Chem. Analyst* 15, 4 (1915).—Weigh 0.5 g. finely ground sample into a 300 cc. Erlenmeyer flask, add 15 cc. satd. soln. H_2AsO_4 , 10 cc. fuming HNO_3 and 3 cc. H_2O satd. with Br. Cover with a watch glass and boil until oxidation is complete and the soln. is clear. Use more HNO_3 if necessary. Evap. to sirupy consistency, add a few crystals KClO_3 and continue evapn. almost to dryness to expel completely the oxides of N. Cool, take up with 50 cc. 10% HCl , heating on the steam bath until soln. is complete. Filter off insol. matter, and dil. filtrate to about 300 cc. From this soln. sulfate may be pptd. and estd. as usual. Wash BaSO_4 thoroughly with hot H_2O to remove Pb salts. The function of H_2AsO_4 is to raise the b. p. of the soln. and promote oxidation. Prepare the soln. by adding As_2O_3 to boiling H_2O until the b. p. is 140°. Analyses of rubber mixes, both cured and uncured, contg. known amts. of S, with or without compounding ingredients or fillers, show the method "accurate to within less than 0.1%." H. M. L.

Hydrochloric acid-ether mixture as a reagent for rubber analysis. DOUGLAS F. TWISS. *India Rubber J.* 50, 199(1915).—Ordinary dil. HCl acts slowly and incompletely on rubber at 100°, but a HCl -ether mixt. acts readily even at ordinary temps., the penetration of the acid being facilitated by the swelling action of the ether. This mixt. is suggested in the proportion of 20 HCl to 30 ether for the estn. of mineral S, all of the sulfide S present being liberated as H_2S , while any SO_4 present is estimated in the residue. 1-2 g. of rubber are treated with the HCl -ether mixt. until it has penetrated the mass, the action usually being complete in 1 day. The Et_2O is then distd. and the mass washed with H_2O and dried; it is then ready for acetone extrn. The best procedure is to begin with 2 samples, extract the free S with acetone, and estimate the mineral and combined S in 1, and the mineral S in the other; the difference indicates the organic S, which in the absence of substitutes is S of vulcanization.

E. J. KELLEY.

Report of committee D-11 on standard specifications for rubber products. E. A. BARRIER, et al. *Proc. Am. Soc. Testing Materials* 15, 1, 408-10(1915).—Proposed specifications for cold-water hose, cotton rubber-lined hose and insulated wire.

E. W. BOUGHTON.

Proposed tentative specifications for insulated wire and cable: 30 per cent Hevea rubber. E. A. BARRIER, *et al.* *Proc. Am. Soc. Testing Materials* 15, I, 411-21 (1915).—A. Conductor. I. Manufacture. Specifications for strand, shape, etc. II. Physical properties and tests. Statement of requirements and methods of testing. III. Permissible variations. B. Insulation. IV. Chemical properties and tests. Limits are given for rubber, waxy hydrocarbons, free S, saponifiable acetone ext., CHCl_3 ext., alc. KOH ext., total S, and sp. gr. The limits for 30% and for 33% compounds differ. The color of the exts. must not be darker than a straw color, the acetone ext. must not fluoresce, and hydrocarbons must be waxy and not darker than a light brown. V. Physical properties and tests. Statement of requirements and methods of testing. VI. Electrical properties and tests. Statement of requirements and methods of testing. C. Inspection. Methods of analysis are given. Discussion follows (pp. 434-9).
E. W. BOUGHTON.

"Balata" from northern Nigeria. ANON. *Bol. inst. imperial* 10, 209; *Rev. industrial agric. Tucuman* 6, 74 (1915).—The sample of "balata" rubber examd. by the Imperial Inst. contained a considerable proportion of moisture and vegetable impurities and was quite dirty and covered with mold; it was white to red in color, and was rather tenacious, but only slightly elastic, and very sticky. The sample lost 26.0% in wt. by washing (due to impurities) and analysis of the residue showed 49.2% caoutchouc, 47.7% resin, 2.4% protein, 0.7% ash. The appearance and physical properties of the original material were greatly improved by converting it into crepe. The caoutchouc which was isolated was almost black and exhibited very inferior physical properties. The "balata" rubber of northern Nigeria is probably derived from *Ficus vogelii*, the preceding data being in accord with the analyses (made by the Imperial Inst.) of samples of the product obtained from this tree in Gambia and the Gold Coast.

H. S. PAINE.

Caoutchouc production from German plants. SCHERMESSER. *Pharm. Ztg.* 60, 591 (1915).—Several plants are mentioned as possible sources of the product, notably *Euphorbia cyparissias*, from which in addition to fat, considerable caoutchouc was obtained.

W. O. E.

Industrial poisons used in the rubber industry. A. HAMILTON. *U. S. Bur. of Labor Statistics*, Whole No. 179, *Industrial and Hygiene Series* No. 7 (1915).—The investigation covered 35 rubber factories and included practically every branch of the rubber industry. In general, and especially in the newer factories, light, ventilation and physical surroundings were excellent. The most dangerous processes are those which involve the use of Pb salts, Sb sulfides, $\text{C}_6\text{H}_5\text{NH}_2$, CS_2 and CCl_4 . Only a small % of the workers, including no women and few boys, are engaged in such operations. A considerable number of workers, including men and boys, are exposed to the lesser danger of fumes of C_6H_6 and naphtha. It is possible to eliminate all such dangers, but their presence is not always realized. Actual cases of poisoning from Pb salts, CS_2 , CCl_4 , $\text{C}_6\text{H}_5\text{NH}_2$ and naphtha were found. Pb compds. are used for molded and mechanical goods, druggists supplies, footwear, clothing, and tires. $\text{C}_6\text{H}_5\text{NH}_2$, CS_2 and C_6H_6 are used in cement. The cold cure of inner tubes requires but little CS_2 or CCl_4 . Bright red goods require Sb sulfide. If rubber clothing is vapor-cured, CS_2 and naphtha fumes may be abundant. Hard rubber contains little or no Pb. The danger of Pb poisoning in dusty compounding rooms could be eliminated by cleanliness and care. The danger from fumes of $\text{C}_6\text{H}_5\text{NH}_2$ in the compounding room could also be eliminated. The dust from mixing mills is harmful if it contains Pb and should be drawn off by means of hoods. After the Pb salts and Sb sulfide have been thoroughly incorporated with the rubber, there is probably no further danger from them in the ordinary handling which takes place in the factory, except in buffing and in grinding

up old rubber for shoddy. Dust-tight covers will eliminate the dangers here. That the Pb in rubber dust is a source of danger was shown by the Thorpe test, *vis.*, digestion with 0.25% HCl for 10 hrs.; appreciable amts. of sol. Pb were found in samples. In the prepn. of cement protection from fumes is necessary, as fumes of CS_2 , C_6H_6 , etc., are evolved. Women and boys are frequently engaged on such work. Much more trouble from naphtha fumes is experienced in dipping and spreading than in cementing. The so-called "dust room," where soapstone dust is used, should be kept clean, but precautions are not often taken. Kettles of melted Pb are a source of danger unless hooded. No matter how carelessly heat-curing is done, the risk to health is slight, but in cold-curing the danger is great enough to cause Europeans to class the rubber industry as a dangerous trade. German regulations forbid more than 4 hrs. work a day at cold-curing. Pb and fume poisoning should be guarded against in the reclaiming process. This process was found responsible for a case of Pb poisoning. The rubber industry is not considered a dangerous one in this country, since relatively few workers are exposed to poisonous dusts or vapors. $\text{C}_6\text{H}_5\text{NH}_2$ poisoning is far less frequent than formerly, but still occurs. Acute, severe naphtha poisoning is rare; but chronic, mild naphtha poisoning is probably very common. Among the workers on dipped goods, CS_2 poisoning is fairly common; it is less frequent, but still occurs, among those who use CS_2 in paint or in vapor curing. CCl_4 is less dangerous than CS_2 . Rubber factories in the U. S. are, almost without exception, lacking in proper protection for workmen, and in consequence the industry is much more unhealthful than it need be. The bulletin contains descriptions of all the processes used and illustrations of arrangements in different factories. Appendices on $\text{C}_6\text{H}_5\text{NH}_2$ poisoning at Akron, Ohio, and on the soly. of Sb sulfide in human gastric juice are given, and also 4 state reports on the hygiene of the rubber industry. E. W. BOUGHTON.

PEARSON, H. C.: **Rubber Machinery.** New York: India Rubber World. 419 pp. \$6.00.

Restoring old rubber. F. MOENCH. U. S., 1,172,158, Feb. 15. Old rubber is covered with a plastic mixt. of linseed oil, turpentine and clay, and heated for 45-60 min. to 160° in a closed retort out of contact with air to soften and restore it.

Vulcanizing rubber. W. E. MUNTZ. Can., 165,820, Nov. 2, 1915. The process of introducing by means of a single treatment (with one solution) on to or into (or both) the fibers of the foundation fabric used in the manuf. of vulcanized rubber goods, a substance which will neutralize H_2SO_3 and H_2SO_4 without the substance, by itself or its products in combination with these acids, having any injurious or deleterious effect on the fabric or the rubber at any time of the process of vulcanization.

Utilizing waste rubber. G. W. BELDAM and A. U. B. RYALL. Brit., 21,445. Oct. 23, 1914. Soles and heels of boots and shoes or sheets, slabs, or pieces for the manuf. thereof are made by disintegrating the clippings or residue, consisting of unvulcanized rubber and canvas, resulting from the making of pneumatic or like wheel tires, and subjecting the homogeneous mass to pressure and vulcanization. The product may be united with a fabric backing.

India-rubber substitutes. V. OTTOREPRETZ. Brit., 21,524, Oct. 26, 1914. An India-rubber substitute is obtained by dissolving S in a vegetable oil, such as linseed oil, and heating the soln. with dil. HNO_3 or other oxidizing agent. A tough elastic substance, which may be vulcanized, is obtained. The substance is formed into a dough-like mass by treatment with CS_2 , benzene, etc. Solns. of resin, India rubber, gutta percha, etc., and filling substances such as chalk, kaolin, pigments, etc., may be added. The mixt. is heated with S to vulcanize it.

The Ten-Year Index is to be published.

Published by the American Chemical Society, Easton, Pa.

Entered as Second-class Matter at the Post-Office, Easton, Pa.

Communications for the Editor should be addressed to E. J. Crane, Ohio State University, Columbus, Ohio.

The Council have voted that no claims for copies lost in the mails can be allowed, unless such claim is received within "sixty days" of the date of issue, nor if due to failure to give sufficient notice of change of address. Charles L. Parsons, Secretary.

Remittances for annual membership dues or for subscriptions, changes of address, orders for subscriptions or back numbers, claims for missing numbers and all matters intended for the Proceedings should be sent to the Secretary, Charles L. Parsons, Box 505 Washington, D. C.

Secretary's Office: Box 505, Washington, D. C.
Eschenbach Printing Company, Easton, Pa.

The American Chemical Society

The Board of Directors of the American Chemical Society has fixed the following schedule of prices for its publications:

Subscription Rates

Journal American Chemical Society.....	\$6.00
Chemical Abstracts.....	6.00
Jour. Industrial and Engineering Chemistry.....	6.00
Two Journals to same address.....	10.20
All three Journals to same address.....	12.60

Back Numbers and Volumes.

	To Members	To Non-members
Single Numbers: J. A. C. S.; J. I. E. Chem. or Chem. Abs....	0.50	0.60
Back volumes { Proceedings, Vol. 1 (1876); Vol. 2 (1877).....	2.00	2.50
{ J. Am. Chem. Soc., Vols. 1-16 inclusive, each..	4.00	5.00
{ J. Am. Chem. Soc., Vols. 17-37 inclusive, each..	5.00	6.00
{ Chem. Abs., Vol. 1, 2, 3 or 5 complete, each..	10.00	12.00
{ Chem. Abs., Vol. 4, 6, 7, 8 or 9 complete, each..	5.00	6.00
Index to Vols. 1-20, J. Am. Chem. Soc.....	0.50	0.75
Index to Chem. Abstracts, Vol. 1, 2, 3, 4, 5, 6, 7, 8 or 9....	1.00	1.00
Jour. Ind. and Eng. Chem., Vols. 1-7.....	5.00	6.00

Foreign Postage, each Journal 75c; Chemical Abstracts, \$1.00 a year.

Special Discounts to Newsdealers, Libraries and Institutions of Learning

Complete sets, Vols. 1 to 37, of the Journal; Proceedings, Vols. 1 and 2; Vols. 1 to 9 of Chemical Abstracts; and Vols. 1 to 7 of the Jour. Ind. and Eng. Chem., may be had of the Secretary.

The following numbers can be furnished only in complete sets, viz.: J. Am. Chem. Soc., 17 (1895), 1-6, 8, 9 and 11; 18, 5; 19, 1 and 4; 20, 3; 22, 4, 9, 10 and 11.

Besides the above, the following numbers can be furnished only in complete volumes, viz.: J. Am. Chem. Soc., 26, 4; 29 (1907) 4, 7 and 9; 30 (1908), 4, 5, 6 and 7; 38 (1916), 1 and 2; Chemical Abstracts, 1 (1907), 2, 3, 12, 13, 14, 15, 16 and 22; 5, no numbers except 1, 4 and 6; 7, 24; Jour. Ind. and Eng. Chem., 1, only No. 11; 2, 12; 3, only Nos. 2 and 8; 4, 3, 4, 5 and 10; 5, 1; 6, 5, 6 and 8; 7, 1 and 8; 8 (1916), 1 and 2.

Advance payment is required and should be made by check or money order only

The Council has voted that the Secretary shall honor claims for non-receipt of publications only if received within sixty days of their issue. Claimants must also directly state that the publication was not delivered at their recorded address. "Missing from files" is no proof of non-receipt.

The Society will not be responsible for loss due to change of address unless notification is received one week in advance of issue.

Members or subscribers desiring their Journals or Abstracts forwarded from an old address should always notify their Postmaster and leave necessary postage.

The names of members and subscribers, whose Journals or Chemical Abstracts cannot be delivered by the Post-Office Department, will be cut off the mailing list at once, and will not be restored until correct addresses have been furnished.

In the absence of other information, the notices of change of address received from the Post-Office Department will be considered as correct, and the mailing list changed accordingly.

All communications should be addressed to

CHARLES L. PARSONS, Secretary,

Box 505, Washington, D. C.

15. Soils and Fertilizers.....	1241		

NOTICE

The Directors of the American Chemical Society have authorized publication of the collective index to the first ten volumes of Chemical Abstracts. It has become evident that the cost of the index will be more than \$10 per copy. In view of this fact the price will be \$10 per copy to all who have subscribed up to the time of this notice (May 10, 1916) and to all members of the American Chemical Society who will have subscribed up to January 1, 1917. The price will be \$12 per copy to all members who will not have subscribed up to January 1, 1917, and \$15 per copy to all non-members who have not subscribed up to May 10, 1916.

The collective author index will be prepared from the annual author indexes after checking these to eliminate errors and to detect omissions. The collective subject index will be compiled directly from the abstracts, both because the annual indexes lack uniformity and because it will be of a form quite different from that of the annual subject indexes, the change being planned in the interest of convenience in use.

Although publication is assured, subscription in advance is still urged on those who will want an index. The size of the edition will have to be gaged on the basis of advance subscriptions. It is the only way to insure obtaining a copy.

PATENTS

Abstracts of patents are included under the appropriate divisions of the journal; those on organic compounds, unless they pertain especially to some other division, are under Pharmaceutical Chemistry. The abstracts of U. S. patents are prepared by Earl T. Ragan, those of Canadian patents by Russell S. Smart, of Fetherstonhaugh & Smart, Ottawa (50 Queen St.), and all others by O. D. Swett. Most German patents are prepared, with permission, from the abstracts in *Chemiker-Zeitung* and Italian patents from those in *Annali di chimica applicata*. All other patents are obtained direct from the specifications.

Copies of any patent may be obtained for: United States, 5 cents, sent to the Patent Office, Washington, D. C.; French, one franc, sent to L'Imprimerie Nationale, 87 rue de Vieille du Temple, Paris; German, one mark, sent to the Patent Office, Berlin; British, eight pence, sent to Patent Office, London (extra postage outside United Kingdom); Austrian, write to the Patent Office, Vienna; Danish, write to the Patent Office, Copenhagen; Norwegian, 1 crown, Patent Office, Christiania; Swedish, 1 crown, Patent Office, Stockholm. Of Canadian patents, manuscript copies only are obtainable. They may be secured from Fetherstonhaugh & Smart, or the Commissioner of

Patents direct. Estimates of cost may be obtained in advance.

In ordering a copy of a patent, the number of the patent, name of the patentee, and subject of the invention should be stated.

CHEMICAL ABSTRACTS

Vol. 10.

MAY 10, 1916.

No. 9

1. APPARATUS.

L. C. JONES.

Suggestions for the manufacture of apparatus for the chemical industries. M. SCHLÖTTER. *Z. Ver. deut. Ing.* 59, 711-2(1915).—A general discussion of structural materials. Galvanic action, action of acids, salt solns., etc., are briefly discussed and suggestions are given as to the selection of materials for the construction of app. for various manufg. operations. F. W. SMITHER.

A new form of absorption bottle for use with either calcium chloride or soda lime in the elemental analysis of carbon and hydrogen in organic substances. H. L. FISHER. *J. Ind. Eng. Chem.* 8, 368-9(1916).—F. describes, with sketches, a new style of absorption bottle with an inner tube fused to the bottom of the bottle and a single hollow ground-in stopper which makes a gas-tight joint in the neck of the bottle and the top of the inner tube. Two kinds of stoppers have been designed. Numerous advantages are claimed. F. W. SMITHER.

Description of a portable gas detector. G. A. BURRELL. *J. Ind. Eng. Chem.* 8, 365-6(1916).—A description, with photograph and diagrams, is given of a portable device for detecting combustible gases in air. Its most important use is for the detection of CH_4 in mine air (fire-damp), but it can also be used for natural gas, coal gas, gasoline vapor, water gas, C_2H_4 , and other combustible gases in air. The app. is 10 to 20 times more accurate than the safety lamp, is lighter in wt., is more rugged and is simple of operation. Percentages of CH_4 in air as low as 0.10% can be detd. The parts are of Al and brass, with a stout gage glass. The instrument carries 4 graduated columns (one for CH_4 and natural gas, one for H, one for gasoline vapor, and one for coal gas) on which the amt. of gas is read off from the height of a H_2O column after the combustion. The elec. energy for heating the Pt wire in the combustion chamber is derived from a miner's elec. cap lamp storage battery (in one form 2 dry cells are used). F. W. SMITHER.

A gas pressure regulator. J. R. POWELL. *J. Ind. Eng. Chem.* 8, 367-8(1916).—P. describes with a sketch a simple pressure regulator that may be easily constructed from material readily obtainable in any lab. F. W. SMITHER.

An apparatus for digesting crude fiber. J. M. PICKEL. *J. Ind. Eng. Chem.* 8, 366-7(1916); cf. *C. A.* 4, 2013.—The distinctive feature of the app. (described in detail) is the round-bottom reflux condenser (Zn or Cu, or an ordinary glass flask with a side-tube on neck). These condensers, through which cold H_2O passes, rest on the beakers in which crude fiber is digesting preventing evapn. and holding frothing in check. F. W. SMITHER.

A furnace for crude fiber incineration. J. M. PICKEL. *J. Ind. Eng. Chem.* 8, 367(1916).—A furnace for igniting 12 detns. in 15 to 20 mins. is made as follows: A piec
9 cr
or
board 0.7 X 19 X 19 cm., in whose center is cut a circular opening
laid on an ordinary lab. tripod. On this board is set a disc of cast
t 2.5 mm. thick and 14.5 cm. in diam. The disc is supported on
screwed into it; on the disc are placed the alundum crucibles (RA
has been filtered, washed, dried, and weighed. The cylinder is

covered with a piece of asbestos board of the same dimensions as the one previously described, but having in its center a hole only 3.5 cm. in diam. A small Bunsen burner, whose gas tip has been widened somewhat, furnishes the heat. F. W. SMYTH.

Simple cell for the determination of hydrogen ion concentration. J. H. LONG. *J. Am. Chem. Soc.* 38, 936-8(1916).—A cell is described which gives results sufficiently accurate for many lines of work and can be easily constructed from material at hand, no complicated glass blowing or expensive stopcocks being required. Comparison with Hasselbalch cells and the use of liquids of known H ion concn. show that measurements can be made with an accuracy of about 0.5 millivolt. Const. readings are secured about 10 min. after filling with liquid and H₂ and shaking. C. A. ROUILLER.

A large fat-extractor. CARL L. A. SCHMIDT. *J. Ind. Eng. Chem.* 8, 165(1916).—An apparatus similar in principle to that used by Benson and Thompson (*C. A.* 10, 398) for extg. tannin from sawdust, suitable for extg. several pounds of material at a charge. H. L. OLIN.

A modification of the Barnard Bishop still. J. J. HINMAN, JR. *J. Ind. Eng. Chem.* 8, 164(1916); cf. *C. A.* 8, 2469.—The gas main in the old type which also served as a support for the burners and flasks is replaced by one made of short sections of 1 in. pipe and 1 in. $\times$ 1 in. $\times$ 1/2 in. tees. H. L. OLIN.

The testing of hydrometers. Bur. Standards, *Circ.* No. 16, 16 pp.(1914).—A detailed account, with illustrations of the methods used in the Bur. of Stds., under the captions: (a) Introduction. (b) Specifications for hydrometers; (1) classes: density, sp. gr., percentage, arbitrary scale; (2) general specifications: standard temp., material, construction, etc., inscriptions, tolerances. (3) Special requirements: alcoholometers, saccharometers, hydrometers for H₂SO₄, Baumé hydrometers, density and sp. gr. hydrometers. (c) Manipulation of hydrometers: observing, influence of temp., influence of surface tension, cleanliness. (d) Tests performed by the Bureau: instruments admitted for test, character of test, control marks. (e) Directions for submitting app. for tests. (f) Fees for testing hydrometers. F. W. SMYTH.

Thermometer with vacuum mantle. E. F. BRUIJNING. *Z. Feinmech.* 23, 52 (1915); *Beiblätter Ann. Physik* 39, 682.—The Hg capillary and scale of the thermometer are inclosed in a high vacuum so that the height of the column is but slightly affected by its surroundings. This arrangement dispenses with the usual uncertain corrections for exposed column. L. W. RIGGS.

Studies of instruments for measuring radiant energy in absolute value: An absolute thermopile. W. W. COBLENTZ AND W. B. EMERSON. Bur. Standards. *Sci. Paper* No. 261, 504-51(1916).—A strip of metal receives the radiation and re-radiates to a thermopile. The strip can also be heated electrically. This gives the absolute calibration; the constants of the thermopile, etc., fall out. The concordance obtained under varied conditions appears to indicate that systematic errors, so very prominent in this field, have here been reduced to 1% or less. The contrivance is thought to be simple enough to be used almost anywhere. Still further simplified, it yields a total radiation pyrometer. W. P. WHITE.

Evaporating apparatus. A. ERNST. *Chem. App.* 3, 37-9(1916).—Descriptions, with 7 cuts, of the Kaufmann, Witkowitz, and Dinkel's app. The W. app. is especially suitable for treating high-boiling liquids as it is built to stand as high as 20 atms. pressure; it requires little floor space and is easily cleaned and repaired. Cf. *C. A.* 10, 297, 708. J. H. MOORE.

Flasks with perforated rim. A. KRIEGER. *Chem. Ztg.* 40, 210(1916).—Two or more small holes are bored in opposite sides of the rim through which a string is drawn over the top of the stopper, tied and sealed with wax. J. H. MOORE.

Respirator. E. J. BEVAN and R. H. DAVIS. Brit., 22,719, Nov. 18, 1914. In a respirator for mine rescue work and the like, the absorbent for CO_2 in the regenerator is made by grinding wood pulp or other form of cellulose with a strong soln. of caustic alkali, such as NaOH .

Filter. BRINJES & GOODWIN and F. TITTERTON. Brit., 22,481, Nov. 13, 1914. A vacuum or natural-subsidence filter comprizes an open-topped casing containing hollow filtering diaphragms and fitted with a hinged bottom for the discharge of the cakes or residue. The filtrate flows through pipes to a receiver which may be evacuated. The cakes may be removed by a reverse flow of air or steam or by mechanical means.

Blast furnace for burning magnesite. AUSTRO-AMERICAN MAGNESITE CO. Aust., 70,686, Dec. 10, 1915. In the burning of magnesite and like substances which form lumpy masses, two rolls, provided with teeth or cutting edges, are arranged before the lower furnace opening, partially closing it.

2. GENERAL AND PHYSICAL CHEMISTRY.

W. D. HARKINS and E. B. MILLARD.

The work of J. H. van't Hoff. G. BRUNI. Smithsonian Inst. *Ann. Rept.* 1914, 767-89.—A biographical sketch. E. J. C.

Arthur Williams Wright. CHAS. S. HASTINGS. *Am. J. Sci.* 41, 361-6(1916). —An obituary with a bibliography of Prof. Wright's most important papers. E. J. C.

Fritz Burmeister. R. *Chem. Ztg.* 40, 181(1916).—Died Jan. 23.

J. H. MOORE.

The atom and the molecule. G. N. LEWIS. *J. Am. Chem. Soc.* 38, 762-85 (1916); cf. *C. A.* 7, 3865 and Bray and Branch, *C. A.* 7, 3865.—Compds. should be classed as polar and nonpolar rather than inorg. and org. These classes are roughly the same. A nonpolar mol. is one in which the electrons belonging to the individual atom are held by such restraints that they do not move far from their normal positions, while in the polar mols. the electrons, being more mobile, so move as to sep. the mol. into positive and negative parts. In an extremely polar mol. such as NaCl it is probable that in the great majority of the mols. the Cl atom has acquired a unit negative charge and therefore the Na atom a unit positive charge, and the process of ionization probably consists only in a further sepn. of these charged parts. If a weakly polar mol. comes into the neighborhood of a more polar one it becomes itself more polar. In this process the weaker bipole stretches and its moment increases. A "cubical atom" is proposed as a basis of a new theory of atomic structure. Thus Li is a cube with a single electron on one corner, Be has 2 electrons, B 3, C 4, N 5, O 6, and F 7. This view is in harmony with the theory developed by Parson, *C. A.* 10, 406. An atom is considered as having an unalterable kernel which possesses an excess of positive charges corresponding in number to the ordinal number of the group in the periodic table to which the element belongs (cf. Thomson, *C. A.* 8, 824). There is a shell of electrons around the kernel which, in the case of a neutral atom, contains negative electrons equal in number to the excess of positive charges of the kernel, but the number of electrons in the shell may vary during chem. changes between zero and 8. The atom tends to hold an even number of electrons in the shell (especially 8 at the corners of the cube) but the electrons may ordinarily pass from one position to another in this shell. Two atomic shells are mutually interpenetrable. The paper is a discussion of these ideas applied to the structure of atoms and compds. E. B. MILLARD.

Molecules as realities. A. PERRIER. *Arch. sci. phys. nat.* 41, 38-47(1916).—Popular lecture on molecular phenomena and the study of mol. motion. E. B. M.

Additivity of the internal atomic heat of ideal gases. M. TRAUTZ. *Elster-Geitel Festschrift* 1915, 333-60; *Beiblätter Ann. Physik* 39, 772-3(1915).—The at. heat is considered as the sum of the translatory and inner at. heats. The former is $\frac{3}{2}R$, and the latter $C_v - \frac{3}{2}R$. The question is raised whether $(C_v - \frac{3}{2}R)$ is identical for both sides of a chem. reaction, if all of the substances taking part in the reaction are ideal gases. For a case in which 2 single atoms form a double atom (e. g., $I + I = I_2$, where the substances on the left have no inner at. heat but that on the right has considerable) it appears that the question must be answered in the negative. T. takes the stand that a free atom is different from one bound in any way, and that the additivity should hold only for the latter. Except for monatomic gases, the additivity principle leads to values of $K = c_p/c_v$ which lie between those calcd. from the Maxwell and Boltzmann theories, and which for polyatomic gases more closely approach the Maxwell values. In a survey of the sp. heat data of gases many tables are given (which show considerable errors in the existing data) for 49 gases containing from 2 to 26 atoms. For about a third of the substances the additivity holds rigidly (in some cases the agreement is excellent), for another third the agreement is rough, and for the rest the values are too large but they are so inexact that the meaning is not clear. The question of whether the additivity of inner at. heat holds for gases in the ideal state or whether it is approximated for gases which deviate from the ideal state to about the same extent is discussed at length without arriving at any definite conclusion. E. B. MILLARD.

Logical basis of the theory of relativity. A. HARNACK. *Ann. Nat. Kulturphil.* 13, 46-51(1915); *Beiblätter Ann. Physik* 39, 569(1915).—H. distinguishes between the equivalence principle (essentially identical with the Einstein relativity principle) and a "relativity" which is valid only when the same motion exists in both system. A further difference is drawn between "true" and "apparent" relativity (which is established only through "accidental" changes in the app.). H. is of the opinion that the theory of relativity furnishes support for the existence of an ether, and not for the Fitzgerald-Lorentz contraction hypothesis. E. B. MILLARD.

Revision of the atomic weight of cadmium. IV. Electrolytic determination of cadmium in cadmium bromide. G. P. BAXTER, M. R. GROSE AND M. L. HARTMANN. *J. Am. Chem. Soc.* 38, 857-67(1916); cf. *C. A.* 9, 735.— $CdBr_2$ was prepd. from Cd and purified Br under dil. HBr, and recrystd., fused in Pt, and again crystallized until the black residue (chiefly C and SiO_2) was eliminated. Samples of this salt were weighed into a cell shaped like a Florence flask with a long wide neck, and were electrolyzed. The Pt anode was fused through the neck of the app.; the cathode was a charge of pure Hg in the bottom of the flask, connected by means of a Pt wire fused through the bottom of the vessel. In general, the method was that employed in the work on $CdCl_2$. A small stream of electrolytic H was passed through the app. during the electrolysis to aid in removing the Br. The ratio $Cd:Br_2$ calcd. from the mean of 12 detns. on samples of 6 to 20 g. each was 0.703282 after applying corrections for air displacement, giving an at. wt. of Cd of 112.407, if $Br = 79.916$. The % Cd in $CdBr_2$ found in this investigation was 41.290, the % Br in the same compd. found by Baxter, Hines and Frevert was 58.708, total 99.998% (*J. Am. Chem. Soc.* 27, 222(1905); 28, 770(1906)). The % Cd in $CdBr_2$ found by Quinn and Hulett (*C. A.* 9, 2613) was 41.257, giving 112.3 as the at. wt. of Cd. E. B. MILLARD.

Revision of the atomic weight of zinc. Electrolytic determination of zinc in zinc bromide. G. P. BAXTER AND M. R. GROSE. *J. Am. Chem. Soc.* 38, 868-73(1916).—The method of expt. and the app. were the same as those described in the preceding

abstract. Zn was purified by electrolysis and recrystn. of the bromide prep'd. from pure Br and Zn. In some expts. the ZnBr_2 was converted to sulfate before electrolysis to save time. After applying the usual corrections to vacuum weights, the ratio $\text{Zn}:\text{Br}_2$ was calcd. from the mean of 10 analyses on samples of 6 to 8 g. each as 0.409103. If $\text{Br} = 79.916$, $\text{Zn} = 65.388$. Richards and Rogers (*Proc. Am. Acad.* 31, 158(1895)) found 70.971% Br in ZnBr_2 ; the present research gave 29.903% Zn, total 100.004%.

E. B. MILLARD.

Method of determining the molecular weight with very small quantities of gases. M. KNUDSEN. *Verh. K. danisch. Wissensch. Ges.* 20, 217-29(1915); *Beiblätter Ann. Physik* 39, 763(1915).—The principle of the method depends on the coeff. of viscous resistance to an object rotating about its axis in the gas under expt. If P is the frictional force with which a gas acts on a surface moving with a tangential velocity of 1 cm. per sec., p the pressure on the gas in dynes per sq. cm., and T its abs. temp., it can be shown from the kinetic theory that the mol. wt. of the gas is given by the equation $M = 522.25 \times 10^8 T(P/p)^2$. A symmetrically blown glass sphere was suspended by a quartz thread in a larger spherical vessel and the damping of the vibrations of the inner sphere was detd. The gas pressure was detd. with a manometer which could detect a change of 0.0002 dyne per sq. cm. The validity of the equation was tested with expts. on O. Values of the mol. wt. were obtained from the logarithmic decrement which varied with the pressure of the gas, but which if extrapolated to zero pressure, gave values in satisfactory agreement with the theoretical. Detns. of the mol. wt. of satd. H_2O vapor down to -75° gave values which were too high, on account of some exptl. error which is being further investigated.

E. B. MILLARD.

Free energy of hydrochloric acid in aqueous solution. JAMES H. ELLIS. *J. Am. Chem. Soc.* 38, 737-62(1916); *Proc. Nat. Acad. Sci.* 2, 83-7(1916); cf. *C. A.* 10, 992.—The prepn. of calomel electrodes, reproducible to 0.05 millivolt, which do not change their value on shaking when in contact with HCl of 0.1 molar or higher concn. is described; and measurements of the e. m. f. of cells of the type H_2 (1 atm.) | HCl soln. | $\text{Hg}_2\text{Cl}_2 + \text{Hg}$ at 18° , 25° and 35° , and with HCl concns. from 0.033 to 4.5 molal are presented. From these e. m. f. values are computed (1) the change in free energy content and in heat content attending the reaction H_2 (1 atm.) + Hg_2Cl_2 (solid) = 2Hg (liquid) + 2HCl at various concns., (2) the change in free energy content and in heat content attending the change HCl (at c_1) = HCl (at c_2), (3) the ratio of the activities of the H ion or Cl ion in solns. of various concns. By combining these results with those derived from Jahn's measurements (*Z. physik. Chem.* 35, 545-76(1900)) of the e. m. f. at 18° of cells $\text{Ag} + \text{AgCl} | \text{HCl} (c_1) | \text{HCl} (c_2) | \text{AgCl} + \text{Ag}$, the series of free energy values is extended from 0.033 to 0.00167 molal and the abs. free energy of HCl (referred to the free energies of the elements as zero) at 18, 25 and 35° in solns. from 0.00167 to 4.5 molal is calcd. and tabulated. From these data and the assumption that at the lowest concn. the ion activity is equal to the ion concn., a series of abs. activity coeffs. for HCl covering this concn. range is computed and these values are compared with the activity coeffs. of KCl derived from the e. m. f. measurements of MacInnes and Parker (*C. A.* 9, 1709) and the osmotic pressure calcns. of Bates (*C. A.* 9, 1710, 2342). The activity coeffs. both from HCl and KCl decrease up to 0.1 molal far more rapidly than do the cond. ratios. The difference at this concn. amounts to 9% for HCl and 15% for KCl, so that in using the conductance ratio as a measure of ion activity in mass action expressions a corresponding error is involved. At about 0.5 molal the activity coeff. of HCl reaches a minimum and then increases very rapidly with increasing concn., becoming 2.23 times as great at 4.48 molal as at zero concn. There is evidence that the conductance ratio is a true measure of ion concn. (but not of ion activity) for KCl.

E. B. MILLARD.

The metastability of the elements and chemical compounds in consequence of enantiotropy or monotropy and its bearing on chemistry, physics and technics. E. COHEN. Utrecht. *Proc. Akad. Wetenschappen* 18, 961-5(1916).—It is pointed out that the non-metals, as well as the metals, are metastable systems because of the existence of several allotropic modifications, and the failure of the substance to become completely transformed to the stable state; S is cited as an example. The same is true of numbers of compounds; expts. with Tl picrate and KNO_3 show that the stable form often persists into regions in which it is unstable, when care is taken to exclude traces of solvent. Hence the pure compd. is in a metastable state, and physical and chem. const. must be redetd. with the pure modifications. GEORGE W. MOREY.

New thermoelectric method for the study of allotropy of iron and other metals. C. BENEDICKS. *Compt. rend.* 162, 297-9(1916).—If a wire is heated locally and this place of heating is gradually moved along the wire (for example by slowly passing the wire through a small elec. furnace) there will be a difference of potential between the ends of the wire if there are 2 phases in it. This method could be applied to the study of allotropy of Fe. In one expt. there was a sharp break in the curve showing temp. plotted against deflections of a galvanometer attached to the ends of the Fe wire at about 875° , in another expt. there was no break. Cu showed no p. d. when passed slowly through the furnace. E. B. MILLARD.

Scientific survey of gas equilibria. H. VON WARTENBERG. *Z. Elektrochem.* 21, 464-9(1915).—A review, with references to the literature, covering the period from the middle of 1913 to the middle of 1915. E. J. C.

Determination of temperature changes in rising and falling gases, and the values of their specific heats calculated from these changes. R. ORHME. *Diss. Marburg*, 106 pp.(1915); *Beiblätter Ann. Physik* 39, 774-5(1915).—In the meteorological part the adiabatic changes of condition of air have been studied. The cooling of an ascending quantity of gas is inversely proportional to its sp. heat at const. pressure, and is given by the equation $dT = -g/Jc_p$, where J is the mechanical equiv. of heat and g the acceleration due to gravity. The presence of H_2O vapor changes the sp. heat only slightly, but is of great importance on account of the changes of state (condensation and freezing) which it undergoes with wide changes in temp. In the physical part, changes of temp. in rising and falling quantities of gas have been measured with a sensitive bolometer, and values of c_p calcd. from them. The value for air agrees within 0.2% with the accepted value, that of H_2O vapor is 6% from the accepted value, and the calcd. values for CO_2 are subject to such wide error as to be of only qual. significance. E. B. MILLARD.

The viscosity of liquefied gases. III. The periodic rotational motion of a sphere in a viscous liquid. J. E. VERSCHAFFELT. Leiden. *Proc. Akad. Wetenschappen* 18, 1038-45(1916); cf. *C. A.* 10, 994.—A math. discussion of the conditions determining the periodicity of motion of a sphere in a viscous liquid. G. W. MOREY.

Cryoscopic measurements at low temperatures. H. S. REID AND D. MCINTOSH. *J. Am. Chem. Soc.* 38, 615-25(1916).—Toluene, CHCl_3 , CCl_4 , MeOH, EtOH, EtOAc, acetone, HOAc, paraldehyde, and CH_3CHO in liquid HBr were studied. The f. p. app. consisted of a double-walled freezing tube immersed in a Dewar tube of ether and CO_2 , in which there was a Pt resistance thermometer and a stirrer. F. p. detns. with the first 3 solutes mentioned above were made to establish the value of K , since these alone showed no evidence of forming compds. with HBr. The latent heat of fusion of HBr was calcd. to be 6.79 cal. per g. from the value $K = 102.3$. Alc. is associated 2.3 to 2.4 times, MeOH 3.4 times, $(\text{CH}_3)_2\text{CO}$ from 2.26 to 3.13, depending on the concn., and HOAc from 2.00 at a diln. of 5.00 to 5.0 at a diln. of 1.25. HOAc

has also an abnormally high cond., which may be due to the presence of H^+ ions as well as complex ions. Oxonium compds. are formed with the solutes contg. O, as is the case when these substances are dissolved in liquid Cl, and a study of the slopes of the f. p. curves shows that these compds. are largely broken up into their constituents in soln. Detns. of mol. wts. in liquid Cl by Waentig and McIntosh (*Trans. Roy. Soc. Canada* 1916 (not yet published)) show normal mol. wts. for ether over a considerable range of concn., but MeOH and EtOH are greatly polymerized. It seems impossible to assign formulas to the oxonium compds. The increase in complexity in soln. as shown by increasing mol. wt. and rapid increase in mol. cond. points to the correctness of the view that the ions are much more complex than would be expected from the oxonium theory.

E. B. MILLARD.

Isomorphism between sodium nitrate and potassium nitrate. M. AMADORI. *Atti r. ist. Veneto* 72, II, 451-60(1912).—A. has carried out expts. to det. the thermal properties of mixts. of $NaNO_3$ and KNO_3 . The ordinary procedure of thermal analysis was followed, the mixt. being heated in glass tubes and the temp. detd. by means of a thermoelement. The point of solidification of $NaNO_3$ was found to be 310° and that of KNO_3 to be 336° . A study of the mixt. shows that the $NaNO_3$ and KNO_3 separate from the fused mass in the form of solid solns. in all proportions. The two forms of crystal are therefore completely isomorphous at that zone of temp (200°). The transition point of KNO_3 from the rhombohedral form to the rhombic is lowered in the mixt. The mol. solubility of the Na salt in the rhombohedral form of KNO_3 is about 10%.

L. T. FAIRHALL.

Dilatometric experiments on the polymorphic alkaline nitrates and on thallous nitrate. M. BELLATI AND L. FINAZZI. *Atti r. ist. Veneto* 69, II, 1151-68(1910).—The method employed in detg. the transformation temps. was an hydrostatic compensation method described by B. and F. (cf. *Atti r. ist. Veneto* 68, 917). The measurements were made in a vaseline bath. The substances studied were freed from adhering air by heating several times *in vacuo*. In the case of KNO_3 , the transformation which occurs at 127.8° is accompanied by a vol. change of 0.0100 of unit vol. at 0° . The $d_{10.6}$ of the salt is 2.1062. $CsNO_3$ has a vol. change of 0.0130 of unit vol. at 0° ; $d_{16.16}$ 3.6415. The transformation of $RbNO_3$ at 161.4° is accompanied by a vol. increase of 0.0185 of unit vol. at 0° ; $d_{17.4}$ 3.0955. The variation in vol. of NH_4NO_3 at its transformation temp. of 86° is -0.0148 and at its second transformation temp. (125°) is 0.0220; $d_{31.9}$ 1.7072. The increases in vol. of $TlNO_3$ at the 2 transformation points 73° and 142.5° are, resp., 0.0034 and 0.0156; $d_{21.4}$ 5.5556.

L. T. FAIRHALL.

Dissociation pressures of mercurous chloride. ALEXANDER SMITH AND R. P. CALVERT. *J. Am. Chem. Soc.* 38, 801-7(1916); cf. *C. A.* 8, 3139; 10, 840.—Dissociation pressures of $HgCl$ between 309 and 384° have been measured with the same app. as before, using either a mixt. of fused KNO_3 and $NaNO_3$ as confining fluid or a mixt. of $LiCl$ and KCl . The results with the latter mixt. are more reliable, since the nitrates slowly react with the vapor. The exptl. values were well represented by an equation of the type $\log p = -7792.10/T - 12.2309 \log T + 49.2048$. The entropy of vaporization to a fixed concn. ($p = 100$ mm. Hg) was calcd. as 17.7 for calomel and was of about this order for the 8 substances recently investigated in this series of papers. NH_4Br had the lowest value, 17.2, and Ph_4I the highest, 20.7. An av. value for normal liquids was 13.5, and for associated liquids 16.3. Cf Hildebrand, *C. A.* 9, 1423.

E. B. MILLARD.

An experiment on the diffusion of carbon dioxide. EDV. BJÖRNSSON. *Borås. Z. physik. chem. Unterricht* 29, 32(1916).—Over 1 end of a glass tube 20-30 cm. long and about 4 mm. inside diam. slip a piece of rubber tubing about twice as long, pass

CO₂ through to displace the air, dip the free end in Hg and close the end of the rubber tubing with a clamp. In about 1 hr. the Hg will rise about 5 cm. in the tube; in 24 hrs. the tube will be full. J. H. MOORE.

The laws of dissolution. HENRY LE CHATELIER. *Compt. rend.* 162, 29-32 (1916).—Le C. replies to Colson's criticism of the application of the Le Chatelier principle to solns. as expressed by the equation $i dC/C = (-500 dT/T^2) p$ (*Compt. rend.* 100, 50(1885)) because of the apparently anomalous behavior of anhydrous Na₂CO₃ and NaCl in liberating heat on soln. but increasing in soly. as the temp. rises. He points out (1) that a contrary view would lead to an absurdity, *vis.*, perpetual motion; (2) that the assertion that the soly. of Na₂CO₃ rises with temperature cannot be proved since the salt hydrates immediately on contact with H₂O; and (3) that the heat of equil. of NaCl at 0° is probably -70 cal. rather than +30 cal. See following abstr.

H. L. OLIN.

Irrational character of the formulas for solubility and the heat of solution. A. COLSON. *Compt. rend.* 162, 222-4(1916); cf. *C. A.* 10, 304, 415, 711.—Largely a polemic with Le Chatelier (preceding abstr.). C. defines soly. as concerned only with the quantity of salt dissolved by a given quantity of H₂O at a given temp., and not at all concerned with whether the salt becomes hydrated or not. The claim of Le C. that the soly. of anhydrous Na₂CO₃ cannot be realized is based on a misunderstanding of the terms used; the results do not support a possibility of perpetual motion as claimed by Le C.

E. B. MILLARD.

The heats of solution of sulfur and of iodine. M. BELLATI AND L. FINAZZI. *Atti r. ist. Veneto* 72, II, 1303-14(1913).—The heats of soln. of S in CS₂ and of I in CS₂, MeOH and EtOH, resp., were measured in a Bunsen calorimeter at 0°. The heat of soln. of S in CS₂ was found to vary from -11.89 cal. (for dil. soln.) to -11.55 cal. (satd. soln.). The values for I in CS₂ varied from -17.65 to -16.65 cal. (satd. soln.). The values for I in MeOH varied from -7.92 cal. to -7.42 cal. (satd.); in EtOH from -4.88 to -5.22 cal. (satd.). The expts. show that the heat absorbed in the soln. of a gram of S and of I in CS₂ decreases with the concn. and that this diminution follows a linear law. The phenomena of soln. of I in MeOH and in EtOH are more complex.

L. T. FAIRHALL.

Viscosity of certain alcoholic solutions. O. F. TOWER. *J. Am. Chem. Soc.* 38, 833-44(1916).—Solns. of LiCl, KI, benzil and urea in MeOH and EtOH at 15, 25, 40 and 50° have been measured in a modified Bingham viscosimeter (*C. A.* 8, 1525) having 2 vertical capillaries about 5 cm. long, one in each arm of the instrument. The app. was calibrated from expiration expts. with H₂O, using the values of Thorpe and Roger, and of Bingham and White. New detns. of the viscosity of samples of MeOH and EtOH contg. very small amounts of H₂O have been made, and detns. on the solns. mentioned above. These results are shown in tables and curves. The "viscosity const." $(\eta' - \eta)/\eta c$ increases with the solvation of the solute, and for the solns. here investigated seems almost independent of the temp.

E. B. MILLARD.

Properties of mixed liquids. II. Phenol-water and triethylamine-water mixtures. J. L. R. MORGAN AND GUSTAV EGLOFF. *J. Am. Chem. Soc.* 38, 844-57(1916); cf. *C. A.* 10, 838.—Surface tensions have been found by the drop-weight method for several concns. of the typical mutually sol. liquids mentioned above at temps. both above and below the critical soln. point. The property-compn. curves are typical and are characterized by the fact that the constituent of lower surface tension depresses that of the other until the max. amt. sol. in H₂O reduces the surface tension of this to a value differing but slightly from that of the other constituent. The effect of the liquid of larger surface tension on that of the other is exceedingly slight. In

the phenol-H₂O curve there is a max. indicating a compd. C₆H₅OH.55H₂O, and in the other system a max. indicating Et₃N.50H₂O. The H₂O layer of such systems must be considered as transformed completely into a compd. and the other layer as the second pure liquid having the compd. in soln. The critical soln. point is that point at which the compd. is miscible in the second liquid. An alternative for the usual adsorption theory of the change of surface tension of H₂O by the addition of other liquids is given.

E. B. MILLARD.

The velocity of esterification of organic anhydrides. R. GUARISCHI. *Atti r. ist. Veneto* 73, II, 449-55 (1913).—G. has measured the velocity of esterification of various org. anhydrides, namely, succinic, maleic and phthalic with different alcs. The alcs. used were methyl, ethyl, propyl and isopropyl. The procedure consisted in heating an equimol. mixt. of anhydride and alc. in sealed tubes at 100° in a glycerol bath. At various times the tubes were withdrawn, broken under water and the acid soln. titrated with 0.1 N soln. of Ba(OH)₂. Acetone was used as solvent for the reacting substances. It was found that the reaction progressed relatively slowly even at 100°. The reaction is probably rather complicated as irregularities were observed in the value of the velocity constant. The reaction between the anhydrides and MeOH is the most rapid. Measurements made at 115° show a great increase in the velocity of the reaction and in this case also irregularity was apparent in the value of the velocity constant.

L. T. FAIRHALL.

Invariant, monovariant and divariant equilibria. IV. F. A. H. SCHREINEMAKERS. Leiden. *Proc. Akad. Wetenschappen* 18, 1018-26 (1916).—A new method is described for representing the sequence of *P-T* curves around an invariant point, and the discussion of the preceding papers (*C. A.* 9, 2728; 10, 991) is continued. In this paper systems with an arbitrary number of components are discussed, and a method given for detg. the sequence of *P-T* curves around an invariant point in such systems, illustrated by application to a system of 5 components. V. *Ibid* 1026-37.—In this paper certain generalizations in regard to *P-T* curves are made. When the *P-T* curves surrounding an invariant point are considered, a "bundle of curves" may be defined as a number of curves which follow one another without being sepd. by metastable prolongations of other curves; e. g., a "3-curvical bundle" is one in which 3 curves follow in sequence, with no metastable prolongations of other curves in between. A similar convention holds in defining "metastable bundles of curves." It is shown that in a *P-T* diagram the same number of bundles (stable and metastable) are situated at the right as at the left of each bundle of curves, and that in every *P-T* diagram the number of bundles of curves is always odd, and at least 3. On this basis the various types of *P-T* diagrams which may exist in a system of a given number of components is readily ascertained. A method of deducing the type of concn. diagram belonging to a given *P-T* diagram is also deduced, and illustrated in a system of *n* components.

GEORGE W. MOREY.

Comparison of the van der Waals' equation with the purely thermodynamic equation of state, and a new method of determining the critical data, limiting density and inversion curves. L. SCHAMES. *Elster-Geitel Festschrift* 1915, 287-306; *Beiblätter Ann. Physik* 40, 7-9 (1916).—Integration of the thermodynamic equation $c_p - c_v = T(\partial p / \partial T)_v (\partial v / \partial T)_p$ gives a "purely thermodynamic" equation of state $p v = RT/m - \int_{\infty}^v [T(\partial p / \partial T)_v - p] dv - \int_0^p [T(\partial v / \partial T)_p - v] dp$. The first integral represents the internal energy on expansion to infinite vol., $-U_{\infty}$; the 2nd the Joule-Kelvin heat on expansion to zero pressure, Q_0 . This equation has been compared with the van der Waals' reduced equation of state. The following characteristic curves are given: (I) Boyle curve $\delta(Q_0 - U_{\infty})/\delta\delta = 0$, (II) the ideal curve $Q_0 - U_{\infty} = 0$, and there-

fore $p = 0$, (III) the differential inversion curve of the Joule-Kelvine effect $(\partial p/\partial T)_H = 0$, (IV) an integral inversion of the Joule-Kelvin effect $\int (\partial p/\partial T)_H dT = 0$, which are shown both analytically and by plotting to be straight lines on the $p-v$ diagram. Exptly. detd. plots for CO_2 , C_2H_4 , O, H and air gave nearly straight lines for curves I and II which intersected at a Boyle point agreeing with the van der Waals value at $p = 9$. This is made the basis for a new method of detg. the critical data and the limiting density. If the minimum points are known for 2 isotherms, the Boyle curve, and hence the Boyle point, is detd., and $p_{\infty} = (p_0)B/9$. If the crit. temp. is known, the "reduced gas const." B may be defined from the expression RT_c/mp_{∞} . Its value for CO_2 is 3.60; for C_2H_4 , O, N and air it has the const. value 3.42, as was shown also from expt., and for H (He) 2.67, in agreement with van der Waals' value. Further, not only the product p_{∞} , but also its factors, may be calcd., since the extrapolated Boyle curve ends at $v = 1.5$. The values of p_c and T_c so obtained agree well with those exptly. detd. The extrapolated ideal curve ends at $\lim_{p \rightarrow 0} v = 0$, $\lim_{T \rightarrow 0} v = 0$, so this may also be calcd., and it leads to exact values of the reduced gas const. B . If this equation holds, T_c may also be calcd., and finally the upper limit of $d_p = \infty$ may be obtained by extrapolation. The inversion curve of the Joule-Kelvin effect may also be obtained from the isotherms, but the value obtained, $(p_{\infty})_I = 16.2$, deviates somewhat from the van der Waals' value 18. The differential inversion curve is almost a straight line ending at $\lim_{p \rightarrow 0} v = 0$, $\lim_{T \rightarrow 0} v = 0$, the integral inversion curve is quite different from the van der Waals' curve, and tends toward $p = \infty$ as T approaches zero. A math. possibility of other characteristic curves in which the attraction coeff. is negative also exists. Amagat's negative attraction value for H_2 appears to be due to the neglect of the term $\partial^2 p/\partial T^2$, so that the physical possibility of a negative attraction seems doubtful. If the solid state is considered, an equation of the 5th degree is obtained, and with n further modifications, one of the $(5 + 2n)$ degree. This may be the physical explanation of the Kammerlingh Onnes equation of state. The conditions which correspond to the virial coeffs. in the Boyle point and in the inversion point have been outlined. The "average empirical reduced" equation of state of K. Onnes satisfies these conditions only for certain values of B . By a combination of these conditions and empirical factors a new equation of state has been derived for very dil. gases, which may be extended to higher pressures by the addition of more terms. E. B. MILLARD.

Simple relation for the heat of vaporization for substances with a reduced gas constant $B = 3.375$. L. SCHAMES. *Verh. deut. physik. Ges.* 18, 35-8(1916); cf. preceding abstr.—If it is assumed that B , and hence also the crit. d., is 1% low, the relation of van der Waals (*Arch. Neerl.* (3a) 1, 90(1911)) $\lim_{p \rightarrow 0} v = 0$, $\lim_{T \rightarrow 0} v = 0$ is exactly satisfied, and B has the value $27/8$, which may be of theoretical significance. Slight variations in the values of B obtained for different gases may be due to the fact that the Boyle curve for these substances is not quite a straight line. By the use of reduced coefficients in the Clausius-Clapeyron equation a function is obtained called f_3 which is defined by the equation $f_3 = 27/8(dv/dT)$, or by $f_3 = B/(v_1 - v_2)$. The value of f_3 , which is a pure number, is 7.00 for C_2H_4 and N, 6.75 for O and 6.375 for A. The relation is suitable for the prepn. of vapor tables from the abs. zero to the crit. temp. for substances whose "reduced" gas const. has the value $3^2/8$. In a future paper these tables, and the heat of vaporization, will be given. The calcs. are a confirmation of the Nernst theory of the heat of vaporization. E. B. MILLARD.

The thermal constants of hydrated sodium acetate. T. GNESSOTTO AND C. FARRIS. *Atti r. ist. Veneto* 70, II, 471-81(1911).—In this investigation, G. and F. have measured the sp. heat of solid and fused $\text{NaC}_2\text{H}_3\text{O}_2 + 2\text{H}_2\text{O}$ and its heat of fusion at 0° . The measurements were made in a Bunsen calorimeter. The fusion of the salt was carried

out in thin-walled glass bulbs heated in baths of fused salts ($\text{Mn}(\text{NO}_3)_2$, $\text{Na}_2\text{S}_2\text{O}_8$, and $\text{NaC}_2\text{H}_3\text{O}_2$). The mean of several detns. of the heat of fusion of hydrated sodium acetate was found to be 38.9 ± 0.1 cal. The sp. heat of the salt between 0° and the temp. of fusion was found to be 0.769. Detns. carried out over the interval 0° – 46.54° show a decided increase in the value of the sp. heat of the solid salt as it approaches the fusion temp.

L. T. FAIRHALL.

Thermal behavior of some compressed and condensed gases at low temperatures.

A. EUCKEN. *Verh. deut. physik. Ges.* 18, 4–17 (1916).—Detns. of the sp. heat at const. vol. have been made for H (gas at several pressures, and liquid), He, solid and liquid A, liquid and 2 solid forms of N, liquid and 3 solid forms of O, liquid and 2 solid forms of CO, and solid CO_2 at various low temps., using essentially the same method as in C. A. 8, 3141. Measurements have also been made of the heat of fusion and of transformation of the various phases of A, N_2 , O_2 , CO, and of the heat of evapn. of H, N, A, O, and CO. No discussion of the results is given.

E. B. MILLARD.

The thermal expansion of salol. A. LEVI. *Atti r. ist. Veneto* 73, II, 185–94 (1913).—Using a dilatometer with Hg as the contact liquid, L. has measured the thermal expansion of salol in the interval 0 – 100° . The sp. vol. of salol at the fusion temp. (40.6°) was found to be 0.774 for the solid phase and 0.846 for the liquid phase. Values are given for the sp. vol. of the solid, fused and superfused substance over the interval 0 – 100° .

L. T. FAIRHALL.

Electron theory of thermoelectric phenomena and electrothermal phenomena.

E. RIECKE. *Elster-Geitel Festschrift* 1915, 71–104; *Beiblätter Ann. Physik* 39, 639–40 (1915).—The Riecke electron theory of 1898 has been briefly and exhaustively treated. The form of the development is the same as in the earlier derivation, except for the Lorentz hypothesis that only the electrons are concerned in metallic conduction, and the Drude addition that the kinetic energy of the electrons is $\frac{1}{2} kT$ if the velocity distribution of the electrons is given by Maxwell's equation. The formulas derived are identical with those of H. A. Lorentz (C. A. 8, 609; 9, 1264, 2029). Under "conduction of heat and electricity," formulas have been derived for the electricity transported with a given quantity of heat and the heat accompanying a given quantity of electricity and for the elec. and thermal cond. during impeded heat flow and elec. flow. A linear temp. coeff. of electron density was found. Equations are derived for contact e. m. f. and thermal force, and for the heating action of galvanic currents in heating circuits. The second law of thermodynamics holds for the reversible heat flow in the direction of the current. The calcd. difference between the Thomson heat for Ag and Cu agreed with the value exptly. detd. With the aid of assumptions as to the mean free path of the electrons, the absolute density of the free electrons in various metals and the abs. value of the contact difference were calcd. from thermal data. The calcd. values of these quantities were too large, which R. explains by stating that the actual diameter of the sphere of influence of the atoms is much smaller than is shown by the value calcd. from the m. p. or in some other way.

E. B. MILLARD.

Study of the lead electrode. F. H. GRIMAN. *J. Am. Chem. Soc.* 38, 792–801 (1916).—The exptl. details were the same as in previous papers (C. A. 9, 267, 1582). Five types of Pb electrode have been studied in a cell: $\text{Pb} \mid \text{satd. soln. Pb}(\text{NO}_3)_2 \parallel 0.10 \text{ N KCl, HgCl} \mid \text{Hg}$, but the only one const. to 0.0003 v. was that in which the Pb was deposited electrolytically on Pt. Freshly cast sticks of Pb, after immersion in acidified solns. of $\text{Pb}(\text{NO}_3)_2$, for varying periods, lost their ductility and other properties commonly associated with Pb, which confirms the work of Heller (C. A. 9, 2339). The gray mass thus obtained is an allotropic modification of the metal. Measurements of the e. m. f. of cells at 0° and 25° in which freshly cast and gray modifications of Pb

formed the electrodes in 0.2 *N* Pb(NO₃)₂ failed to give any indication of the transition temp. The normal electrode potential of Pb at 25° is 0.1318 v. Photomicrographs of the specimens were made showing the rapidity with which freshly cast Pb undergoes transformation to the gray modification in acid solns. of Pb(NO₃)₂.

E. B. MILLARD.

Study of the action of alkali on certain zinc salts by means of the hydrogen electrode. J. H. HILDEBRAND AND W. G. BOWERS. *J. Am. Chem. Soc.* 38, 785-8 (1916).—The exptl. method employed was essentially that of *C. A.* 7, 3070. It is incorrect to write the reaction between Zn(OH)₂ and excess alkali as $H_2ZnO_2 + 2OH^- = 2H_2O + ZnO_2^{--}$; e. m. f. detns. during a titration with alkali showed the reaction to be $H_2ZnO_2 + OH^- = H_2O + HZnO_2^-$. This is to be expected since the 2nd H ionizes much less readily than the first in all dibasic acids, and it would be strange if the first main product of neutralization of Zn hydroxide were a soln. of Na₂ZnO₂. Another break in the e. m. f. curve indicated the existence in soln. of acids of the type HZnBr₂, HZnI₂, and HZnCl₂, as well as possibly HZn₂Cl₄. From the shape of the curve the ionization const. of HZnX₂ was estd. as about 4×10^{-4} . No indication of the neutralization of the second H was found. Part of the alkali is adsorbed, changing the coagulum of Zn(OH)₂ to a suspension, and part neutralizes the hydroxide, giving the acid zincate.

E. B. MILLARD.

Extrapolation of conductance values. MERLE RANDALL. *J. Am. Chem. Soc.* 38, 788-92 (1916).—It is proposed to plot $\Delta T/Cl/\alpha KCl$ (e. g.) against the square root of the ion concn., and extrapolate to zero concn., as a much quicker method of getting a Λ_0 value. In this method degree of dissociation (α) of the reference salt is detd. by any of the older and more laborious (but reliable) methods. Examples are given to show that this method gives values of Λ_0 which agree with those by other methods. H. C. Jones is criticized, first for reporting cond. values in the obsolete Siemen's units, and second, for assuming that the highest diln. measured represents complete dissociation.

E. B. MILLARD.

Recent developments in electromagnetism. EUGENE BLOCH. *Smithsonian Inst. Ann. Rept.* 1914, 223-41.—The following subjects are discussed: (1) the dynamics of the electron and electromagnetic mass; (2) the principle of relativity; (3) electromagnetism and radiation; (4) the magneton; (5) the production and nature of gaseous ions; (6) photoelec. effect.

E. J. C.

Absorption spectra of liquefied gases in the ultraviolet. L. CIECHOMSKI. *Inaug. Diss. Freiburg (Schweiz)* 1910, 83 pp.; *Beiblätter Ann. Physik* 39, 240-1 (1915).—ZrO₂ and ThO₂ were ignited in a Pt flask with any oxy-acetylene flame and the light radiated from them was used as a source of light in the expts. This allowed an extension of the O₂-H₂ flame range somewhat, but the light was very weak at 235 μ . Condensed Al sparks under H₂O, generated by a simple app. described by C., gave a continuous spectrum to $\lambda = 214 \mu$, but it was very weak at $\lambda = 220 \mu$. The absorption expts. were carried out in a vessel having parallel quartz sides which were optically plane. With liquid O 13 bands were found, of which 5 could be placed in band groups. Equiv. quantities of liquid and gaseous O do not show the same end absorption; the liquid O causes a shift of the absorption limit in the direction of the little-refracted wave lengths. N is very permeable in the ultraviolet. Liquid air gives the absorption spectrum of O. There are no bands in the visible range for Cl; there is strong absorption in the ultraviolet, which, for thin films, resembles that of gaseous Cl. The high absorptive power of the halogens is lost in their H compds.; absorption is first observed in the ultraviolet, and the limit is shifted toward the visible spectrum as the at. wt. of the halogen increases. H₂S shows a partial absorption in the ultraviolet which is

much stronger than that of H_2O . In spite of the fact that N is so transparent to ultraviolet, NH_3 absorbs strongly in this region. SO_2 shows a selective absorption in the beginning of the ultraviolet and becomes completely absorbing for the shorter wave lengths.

E. B. MILLARD.

Primary high frequency spectrum of iodine and tellurium. MANNE SIEGBAHN. *Verh. deut. physik. Ges.* 18, 39-40(1916).—To throw light on the contradictory results with secondary X-ray spectra obtained by Malmer (*C. A.* 9, 1144) and deBroglie (*C. A.* 8, 2650, 3150; 9, 2350), S. has detd. the primary spectrum by means of a chilled anticathode of Ag on whose surface some of the element was placed. The photographs obtained with a rotating salt crystal showed sharp lines for Ag and the α_1 and β_1 lines for the other element. If values of $(1/\lambda)^{0.8}$ are plotted against atomic numbers a straight line is obtained for both α_1 and β_1 if the order is Cd, In, Sn, Sb, Te, I, . . . , Ba, thus adding evidence to the belief that the anomaly of I and Te is one of at. wt. and not of at. number.

Oil films on water and on mercury. HENRI DEVAUX. Smithsonian Inst. *Ann. Rept.* 1914, 261-73.—A summary of D.'s work during the past 10 years.

E. J. C.

An interpolation formula for resistance thermometry at low temperatures. F. ZERNIKE. *Proc. Akad. Wetenschappen* 18, 914-26(1916).—Z. makes the assumption, based on theoretical considerations, that the resistance of a pure metal and its 1st, 2nd and 3rd differential coeff. with respect to T vanish at abs. zero, and that impurities may be corrected for by dropping the 1st of these conditions. One of the possible expressions for the above condition is $R = T^4/(aT^3 + bT^2 + cT + d) + r$, or $R = Cr/(1 + \alpha r^{-1} + \beta r^{-2} + \gamma r^{-3}) + r$, in which $\gamma = 0.01T$. The formula was tested by applying to the results of Onnes and Holst on the resistance of Pt down to the liquid He temp., and found to represent the results within exptl. error (0.02°). For the Pt wire in question, $\alpha = 0.1536$, $\beta = 0.1255$, $\gamma = 0.0958$. The formula was also applied to Au and Hg, with satisfactory agreement with expt. A single formula to fit both above and below 230° abs. could not be obtained; introduction of a T^2 term, as in the Callender formula, causes large deviation at low temp.

A new alpha-ray effect. F. H. GLEW. *J. Röntgen Soc.* 11, 77-80(1915).—It has been observed that when a very thin sheet of mica is exposed to bombardment by α -rays, the sheet soon becomes curved with the convex surface towards the source of the rays. If the mica sheet is too thick to bend a strain is produced. These mechanical effects are cumulative and do not appear to be reversible, persisting through a great range of temp. If the radiated piece of mica is split into successive layers, it is found that the curvature resides in the layer which has been nearest to the source of the rays. It is suggested that by refined methods, using a suitable piece of mica as one plate of an interferometer, it may be possible to register and permanently to record a few α -particles, perhaps a single one.

W. H. ROSS.

Asymmetrical diffraction and rediffraction of X-radiation from Coolidge and ordinary tubes. I. G. RANKIN AND W. F. D. CHAMBERS. *J. Röntgen Soc.* 11, 41, 81-5(1915); cf. *C. A.* 9, 752.—The asymmetry is shown to be distributed around a point at about 15° from that at which light, substituted for cathode rays, would be reflected. With ordinary bulbs having platinized Ni or W anticathodes, there is, at this point only, sensible symmetry shown by an annular black band within the rim of the image having an inner white border. In the case of Coolidge tubes, it has been ascertained that although the principle of the distribution still holds, there are significant changes in the effects. Thus (1) the black and white bands are everywhere asymmetric, i. e., there is no symmetric "optimum;" (2) the point around which the asymmetry is distributed lies in the axis of the cathode rays themselves, where, if such observations could be taken, there would be minimal diffraction; (3) the diffraction appears as crescent arcs in place of more or less concentric rings; (4) with ordinary bulbs the breadth of the bands in different positions of the bulb varies imperceptibly when the distance is const., but with the Coolidge tube the breadth of both bands varies in a marked degree directly as the distance from the axis of the cathode stream. Negatives of the second diffraction of the already diffracted radiation show that its image-forming power is still further altered or transformed, e. g., images of circular apertures when the obstacle is placed in an asymmetric position appear as the 2 adjacent sides of squares. With the Coolidge tube there is on one side of the aperture a faint concentric band and on the other a prolongation, or "tail," of double structure which could only have been produced by radiation deviated up to 45° from its path between plate and obstacle (4 cm.). Thus the expts. would seem to show that the origin of the asymmetry, if not of the primary rays themselves, lies in the cathode stream. Cf. Rutherford and Andrade, *C. A.* 8, 3754; Laub, *C. A.* 8, 3529, 3754.

W. H. ROSS.

X-Ray sensitometry. ORIN TUGMAN. Eastman Kodak Co., Rochester. *J. Röntgen Soc.* 11, 121-4(1915).—In the Hurter and Driffield method for detg. the

sensitiveness of photographic materials to light, curves are plotted with densities, *i. e.*, degree of blackening of the photographic negative, on one axis, and the log of the exposure along the other axis. If the straight line part of any particular curve be extended to cut the latter axis, then the portion of this axis thus intercepted will represent the inertia of the photographic plate, and will give a measure of its speed. Expts. are described which show that the curve obtained from action of X-rays on an emulsion is similar to that obtained by the action of light except that the X-rays act throughout the thickness of the film, but this difference is to some extent masked, especially in thick coatings, by the slow penetration of the developer. The sensitiveness of photographic materials to X-rays, however, cannot be found in the same way as to light, but must be considered as the density which can be obtained for a given exposure with development continued to the limit. W. H. ROSS.

The spectrum of X-rays. B. CABRERA. Madrid. *Nature* 96, 144(1915).—Kossel (*C. A.* 10, 552, 1715) discussing the previous measurements of the frequencies of the corresponding lines of the spectrum *K* and *L* characteristic for different elements established certain numerical relations which were confirmed in a more general way by Wagner (*C. A.* 9, 2033) and by Bragg and Pierce (*C. A.* 10, 21). From among these relations attention is now specially directed to the one obtained by generalizing the second law of Kossel: $M_{\alpha} = L_{\gamma} - L_{\alpha}$. In this equation each term expresses the frequency of the lines and with its help the frequencies of the principal lines of the spectrum of the *M* characteristic may be detd. if L_{γ} and L_{α} are known. Using Bohr's model for the atom as modified by Kossel, *i. e.*, supposing that in the transit of an electron from one ring to another a quantum is emitted, the frequency of which is detd. by Bohr's formula, the radiation *M* will correspond to the transit of an electron from the fourth to the third ring, and the corresponding frequency, $\nu = 1.59 \times 10^{14}(N - a)^2$ will be emitted. The exactness of the prediction has been demonstrated by the good agreement in the values found for ν when calcd. for several of the elements by means of the first formula starting from the values of L_{γ} and L_{α} given by Mosely, Rutherford and Andrade, and when calcd. for the same elements by application of the second formula. W. H. ROSS.

The charge of radioactive recoil. L. WERTENSTEIN. *Compt. rend.* 161, 696-9 (1915); cf. *C. A.* 8, 2525.—An exptl. study was made of the question of the charge of recoil atoms in the case of Ra D projected during the transformation of Ra C. Owing to the extreme absorbability of recoil atoms in matter, it is possible to sep. the effect which they produce from that of the α -rays. Measurements were accordingly made of the charge received by a cylinder receptor (1) when the rays had no obstacle to traverse; (2) when they were filtered through a screen of Al foil 0.7μ thick; (3) when they had to traverse a sheet of Al 0.5 mm. thick which arrested all the α -rays. The difference between (1) and (2) gave the value of the charge of the recoil atoms, and the difference between (2) and (3) gave the charge of the α -rays. In carrying out this expt. the whole app. was inclosed in a vessel which was evacuated to as high a degree as possible, and by operating an electromagnetic control from the outside the screens could be moved without opening the vessel. It was found that when the pressure was reduced to 0.6 dynes per sq. cm. the atoms of Ra D when projected do not carry an elec. charge, but when the pressure is increased they gradually acquire a positive charge which becomes equal to and may even surpass that of the α -rays. The results obtained are explained on the grounds that at the moment of their production the atoms of Ra D are not charged. Their positive charge is only a consequence of their collision with the mols. of the surrounding gas which brings about a sepn. of one or more electrons from the radioactive atom. The pressure under which the radiation of recoil attains a charge equal to $1/2$ that of the α -rays corresponds with a free path of the atoms

projected equal to the distance of the source from the receptor. On the assumption that each collision gives rise to the production of a pair of ions the exptl. results show that the mean free path at a pressure of 1 dyne per sq. cm. is 100 mm., while the value calcd. from the ionization produced is 90 mm. Since the free path of a particle of Ra C calcd. in the same way for the initial portion of the path is 440 mm., the recoil atoms at their commencement therefore ionize 5 times better than the α -rays.

W. H. ROSS.

The atomic weights of isotopic thorium and ionium. O. HÖNIGSCHMID. Radium Inst., Vienna. *Z. Elektrochem.* 22, 18-22(1916).—The at. wt. of Th was found to be 232.150 from the ratio $\text{ThBr}_4/4\text{AgBr}$ and 232.152 from $\text{ThBr}_4/4\text{Ag}$. The bromide analysis is accurate because ThBr_4 does not absorb an excess of Br when melted and sublimed in a stream of Br, and at temps. below 800° it does not attack quartz app. This Th was spectroscopically free from all impurities including the rare earths. The same method was then applied to a Th-Io mixt. obtained from the residues after extrn. of U from Joachimsthal pitchblende. The sample was spectroscopically identical with the pure Th but was rich in Io and sufficiently radioactive to give a luminescence. Its at. wt. from the ratio $(\text{Th-Io})\text{Br}_4/4\text{AgBr}$ was 231.503, and from $(\text{Th-Io})\text{Br}_4/4\text{Ag}$ was 231.507. Theoretically the at. wt. of Io is near 230.0, so that the difference of 0.65 unit in the at. wt. of Th is due to an admixture of 30% Io. G. L. WENDT.

The relation between the radioactivity of Swedish springs and the chemical composition of the rocks through which they flow. NAIMA SAHLBOM. *Arkiv Kemi. Min. Geol.* 6, No. 3, 1-52(1915).—An examn. of the radioactivity of 394 deep-bored wells and open drinking springs from different geological areas in Sweden showed a variation in activity of from 0.3 to 172.2 Mache units per l. of water. A marked contrast in radioactivity was noted between spring waters from sedimentary deposits and from the primary rocks. The former gave an av. of 4 and the latter of 23 Mache units. Of the springs from the sedimentary rocks, those from limestone showed the weakest activity, averaging 1.9 units; those from schist showed an activity of 27 units while those from sandstone which were most active averaged 7.1 units. In the case of deep-bored wells a close relationship was also noted between the radioactivity of the water and the chem. compn. of the rock through which they flowed. Thus the highest activity was found in wells bored in the acid rocks, granite and syenite; those in the ordinary gray gneiss and the strongly-pressed granite took an intermediate position; while a few springs in diabase showed a weak activity which did not exceed the value found for sedimentary rocks.

4. ELECTROCHEMISTRY.

COLIN G. FINK.

Utilization of electric power in electrochemical and electrometallurgical industries (of Switzerland). C. BAUR. *Elektrotechn. Z.* 36, 694-5(1915). C. G. F.

Single-electrode electric furnaces for making and refining steel. ANON. *Elec. World* 67, 670(1916).—The Snyder furnace is made as nearly spherical as possible, as this form has the largest ratio of vol. to surface. Furnaces are designed to make 10 heats per 24 hrs. and a 200 ton per day furnace occupies a floor area of 40 sq. ft. A thorough circulation of the bath is claimed. Three installations are briefly described of 200, 350 and 750 kw. capacity, respectively, and these show an energy consumption of 500-525 kw. hrs. per ton of steel.

W. E. RUDER.

Materials adapted for lining electric furnaces. O. PETERSON. *Mining Eng. World* 43, 695(1915).—The walls of a basic furnace above the slag line may be SiO_2 .

MgO, or chrome brick. MgO brick has the longest life, but is much more expensive. Chrome brick is not cut by molten SiO_2 , and is neutral to acids and bases. The roof of the furnace must consist of SiO_2 brick as no basic lining has been discovered which will retain the shape of an arch of appreciable span without spalling. SiO_2 brick is used throughout in lining an acid furnace.

W. H. BOYNTON.

Electrolytic refining of tin. A new American industry. ANON. *Elec. Rev. West. Elec.* 68, 507(1916).—About 45,000 tons of Sn are imported annually of which 90% comes from Straits Settlements. Bolivian metal does not lend itself to Sn plate production, because of impurities, particularly Pb, Sb and Cu. A new electrolytic refining plant of the Am. Smelt. & Ref. Co. will utilize about 14,000 tons of Bolivian ore. A syndicate in Seattle, Wash., is also contemplating building a smelting and refining plant to handle Alaskan and also Bolivian ores.

W. E. RUDER.

Electrolytic precipitation of bronze. W. D. TREADWELL AND E. BECKH. Charlottenburg. *Z. Elektrochem.* 21, 374-80(1915).—Expts. have been carried out for the purpose of detg. the capacity of Sn and Cu to form alloys. A number of bronze baths have been studied. For red bronze, a caustic alkali oxalate-cyanide bath, containing 25 g. CuSO_4 , 35 g. KOH, 52 g. KCN, 18.5 g. $\text{K}_2\text{C}_2\text{O}_4$ and 26.1 g. of SnCl_4 per l., is recommended and for gilt bronze, a caustic alkali cyanide-sulfide bath, containing 25 g. CuSO_4 , 35 g. KOH, 52 g. KCN, 26.1 g. SnCl_4 and 78.1 g. Na_2S per l.

New electrolytic plant at Boston. ANON. *Elec. Rev. West. Elec.* 68, 540(1916).—Brief announcement of the new Boston Electrolytic Oxygen Co. plant. The O is guaranteed 99.3% and the H 99.9% pure. The O is compressed into metal cylinders.

C. G. F.

Anode and Wehnelt effects. G. OESTERHELD AND E. BRUNNER. *Z. Elektrochem.* 22, 38-48(1916); 8 illus.—In the electrolysis of molten salts, the current increases gradually as external resistance is cut out until a critical value is reached at which the voltage rises and the current falls off rapidly. The change is accompanied by sparking at the anode and by singeing of the resistance. The influence of varying conditions on this anode effect were studied with molten NaBe_2F_6 as electrolyte, and a number of oscillographs taken to aid in detg. its nature. The critical max. c. d. varies within wide limits with the physico-chem. properties of the molten salt. The effect is due to the gradual but never complete covering of the anode with a layer of gas resulting in arc discharges through the gas film which shift from place to place. The Wehnelt effect as utilized in the Wehnelt interrupter depends on the presence of self-induction in the circuit. The discharge is caused by the ignition of an explosive gas mixture surrounding the anode. Due to the low b. p. of aq. electrolytes, there is no possibility of a sufficient rise in temp. to permit of a true arc; such an arc in the anode effect is possible with high b. p., highly viscous and poorly adhering molten salts.

E. SCHRAMM.

The hot cathode argon gas-filled rectifier. G. S. MEIKLE. *Gen. Elec. Rev.* 19, 297-304(1916).—A new low-voltage rectifier for rectifying currents within a wide range is described. A simple type of this rectifier is shown in the accompanying fig. G is a hermetically sealed bulb, 7.6 cm. in diam., made of heat-resisting glass. The cathode C is a fine W wire supported between 2 W leads; A is a solid W anode of relatively large cross section and a smooth surface. The bulb is filled with 3 to 8 cc. of argon free from all such impurities as would readily attack the W electrodes. It is absolutely essential that these impurities be absent, as even traces will produce a very

rapid disintegration of the cathode and eventually render the rectifier ineffective. To ensure against the accumulation of impurities that might distil out of the glass or the electrodes, solid substances are introduced into the bulb which, when vaporized, will react readily with these impurities. In the fig. the purifying agent *P* is fastened to one of the cathode leads. As soon as impurities are liberated by the glass or electrodes the voltage across the gap increases and the increased energy consumption causes the cathode leads to heat up and the purifying agent to begin to vaporize. The vapor combines with the impurities and the high state of purity of the argon gas is reestablished. Expts. show that rectification is possible with all pressures of A. With an increase in the gas pressure the potential at which the arc is established increases. In starting the rectifier a. c. passes through the cathode filament: electrons are liberated from the filament and through the mechanism of ionization + ions are produced which, with the electrons, carry the unidirectional current of the arc. The rectifier is self-starting and self-maintaining. The life of the rectifier is 900 to 3000 hrs. The arc drop is 4 to 8 v. In one test the rectifier was connected into a 236 v. 60 cycle a. c. line and furnished 6.2 amp. to 89 storage battery cells connected in series. total d. c. voltage was 224. No auxiliary starting load is required when beginning a battery charge. Other details are given. C. G. F.

The production of constant high potential with moderate power capacity. A. W. HULL. *Gen. Elec. Rev.* 19, 173-80(1916).—Heretofore all attempts to produce high voltage d. c. of more than very small power capacity have met with little success. H. describes a new and comparatively simple method, based upon the kenotron (*C. A.* 9, 1008), for producing 1 to 50 kw. at voltages between 10,000 and 200,000 v. Details and diagrams are given. C. G. F.

The conductivity and electric excitability of liquid insulators. D. HOLDE. *Z. Elektrochem.* 22, 1-5(1916).—The purpose of the expts. described was to det. the danger of fire due to possible accumulation of charges when filling vessels with such liquids as benzine, petroleum ether, benzene. It was found that any charges produced were quickly transferred to the walls of a conducting vessel and at once dissipated if this was grounded. The addition of small amounts of EtOH or HAc, by greatly increasing the cond. of the liquid, acts as a further safeguard. E. SCHRAMM.

Earth resistance and its relation to electrolysis of underground structures. B. MCCOLLUM AND K. H. LOGAN. *Bur. Standards, Tech. Paper* 26, 48 pp.(1915).—The resistivity of the soil in which metallic structures are buried is of much importance with respect to electrolysis. Three methods of measurement, Wenner's method, the guard ring method and the compression method, are described. The first two do not require removal of the soil from its original position. All three are satisfactory for practical purposes, though each has advantages over the others under certain conditions. Soils from different localities showed great variation in resistivity, the majority showing 1000-5000 ohms per cu. cm. Increasing the pressure on a sample of soil tends to increase the conductance slightly, especially if the original pressure is low. Unless a soil is satd. with H₂O, increase in H₂O increases the conductance. The amt. and kind of sol. matter in the soil affect the resistivity. Resistivity increases as the temp. falls, especially when the f. p. of H₂O is reached. Flow of current through soil temporarily increases resistivity in the neighborhood of the electrodes. Considering the relation of soil resistivity to electrolysis, the importance of good rail bonding and well drained roadbed is pointed out. The relations of the various factors affecting leakage resistance, namely, character of soil, pressure, moisture, freezing, and polarization, and surface films to the electrolysis problem are described. A knowledge of the resistivity of the soil is important in estg. the danger indicated by the potential difference and the potential gradient measurements. Temp. and H₂O content of a

soil affect the amt. of current escaping from a grounded track used as a return circuit, and these factors must be considered in the interpretation of data from an electrolysis survey.

E. W. BOUGHTON.

The influence of frequency of alternating or infrequently reversed current on electrolytic corrosion. BURTON MCCOLLUM AND G. H. AHLBORN. *Bur. Standards. Proc. Am. Inst. Elec. Eng.* 1916 (advance copy); *Met. Chem. Eng.* 14, 389(1916).—The frequency of the currents used varied from 60 cycles per sec. to a 2-week period. Pb and Fe electrodes were buried in soil, part of the tests being run outdoors and part in earthenware jars in the lab. The c. d. was 0.5 milliamp. per sq. cm. for Fe. A run lasted 15 to 20 days, and the test pieces were weighed before and after. The results show, (1) that a decrease of corrosion occurs with an increase in frequency; (2) that the corrosion is practically negligible below a 5-min. period; (3) that with Fe electrodes a limiting frequency is reached between 15 and 60 cycles per sec., beyond which no appreciable corrosion occurs; no such limit was reached in the Pb tests, although it may exist at a higher frequency than 60 cycles; (4) that with periodically reversed currents, the addition of Na_2CO_3 to the soil reduces the loss in the case of Fe, and increases it in the case of Pb; (5) that the loss of Pb in soil on d. c. is about 25% of the theoretical loss; and (6) that alternating or reversed current with as long periods as a day or a week would in the case of Fe materially reduce the damage to underground structures. In the so-called neutral zone of street railway networks where the pipes continually reverse in polarity, the damage is much less than would be expected from a consideration of the arithmetical average of the current discharged from the pipes into the earth. Where the pipes are alternately + and — with periods not exceeding 10 or 15 min., the algebraic sum of the current discharged is more nearly a correct index of the damage that will result than any other figure that can readily be obtained. The reduction in corrosion due to periodically reversed currents appears to be due to the fact that the corrosive process is in a large degree reversible, so that the metal removed during the half cycle when current is being discharged is in large measure redeposited during the succeeding half cycle, when the current flows toward the metal. This redeposited metal may not be of much value mechanically, but it serves as an anode surface during the next half cycle, and so protects the uncorroded metal beneath. The extent to which the corrosion is reversible depends upon the freedom with which the electrolyte circulates, and particularly, on the freedom of access such substances as O or CO_2 which may result in secondary reactions giving rise to insol. ppts. of the corroded metal. It is largely for this reason that the corrosion becomes greater with a longer period of the cycle, since the longer the period the greater will be the effect of these secondary reactions. The paper was discussed by Cushman, *et al.*

Fixing nitrogen. SOC. GÉNÉRALE DES NITRURES. *Brit.*, 22,586, Nov. 16, 1914. A mass containing AlN is obtained by moistening and exposing to the air the product prepd. by heating, at the temp. of the elec. furnace, a mixt. of C and bauxite or other aluminous bodies, with or without a quantity of Fe depending on the proportion of Fe in the aluminous product. The mass is pulverized before treatment, and sawdust or other porous materials may be added to assist the distribution of the H_2O . The reaction is accompanied by the production of combustible gases and by the raising of the mass to a high temp., and after this rise in temp. has taken place, the reaction may

be continued in an atm. of more or less pure N. The speed of the reaction is increased by employing air or N under pressure, or by blowing these gases over or through the mass. The surplus heat produced in the process may be utilized to effect the combination of N with other materials added to the mass, such as bauxite and C. It is preferred that there should be 30-60% of Fe in the mass to be treated; in an example the product is prepd. from a bauxite containing Si and Ti, by heating with coke or wood charcoal in an elec. furnace, molten Fe, or Fe_2O_3 and C, being added during the operation to increase the proportion of Fe in the product.

Electrolytic production of hydrogen peroxide. HENKEL ET CIE. Brit., 22,714. Nov. 18, 1914. App. for mfg. H_2O_2 by the use of O under pressure comprizes a strong

metal tube A fitted with screw caps B, B' and lined with material such as Ag amalgam or Cu amalgam forming the cathode. The caps are lined with protective material. A jacket H may be provided so that the tube A can be cooled by brine. Axially within the tube A is an anode rod C enclosed in a tubular diaphragm of asbestos fabric or other material. O is forced into the lower cap B' through a nozzle producing fine bubbles. Excess of O may be supplied in order to agitate the electrolyte, which enters at the lower cap and escapes through the upper one. Strong peroxide solns. may be obtained by successive passage through several app., which may be elec. connected in series, or by repeated passage through one app. O sepg. from the product is returned to the compressors. Cf. C. A. 9, 1013.

Lixiviating copper and silver ores. H. B. SLATER. Can., 165,980, Nov. 9, 1915. Process for producing a lixiviant for ores of Cu and Ag, by subjecting a soln. of NaCl together with FeCl_2 to electrolysis, thereby oxidizing the FeCl_2 to FeCl_3 , adding a metallic hydroxide to the soln. at the anode and continuing the electrolysis to produce free HClO and ferric chloride.

Separating and cleaning grain. J. KRAUS. Aust., 70,601, Dec. 10, 1915. The treatment is electrolytic.

Drawing wire. R. JAHODA and ELEK. GLÜHLAMPENFABRIK "WATT" SCHARF, LÖTTI & LATZKO. Aust., 70,611, Dec. 10, 1915. The wire is coated with lubricant before passing through the die.

Tungsten wire. WESTINGHOUSE METALLFADEN-GLÜHLAMPENFABRIK GES. M. B. H. Aust., 70,613, Dec. 10, 1915. Before the mechanical operations of hammering, rolling, and drawing the heated rod, or between these operations, the metal is exposed to the action of vapors of S, Se, Te, or their compds. (e. g., H_2S , H_2Se , H_2Te), or similar substances which leave deposits removable later without injuriously affecting the material, preventing oxidation of the heated metal and facilitating rolling and drawing.

J. H. MOORE.

Reaction mechanism of the azoimide synthesis from hydrazine and nitrous acid. FRITZ SOMMER AND HEINRICH PINCAS. Berlin. *Ber.* 49, 259-77(1916).—The reaction between N_2H_4 and HNO_2 is in reality much simpler than might be assumed from the

contradictory observations reported in the literature. Strict distinction must be made between the reaction in acid and in neutral soln. In the latter case (C. A. 8, 306), from 1 mol. each of N_2H_4 and HNO_2 is formed the salt $N_2H_4NO_2$ which on heating, both in the solid form and in aq. soln., decomps. quant. into NH_3 , N_2O and H_2O . Free HNO_2 enormously accelerates this decompn. so that the dinitrite cannot be prepd., as it dissociates into $N_2H_4NO_2$ and free HNO_2 , the latter catalyzing the above decompn., but as it is neutralized by the NH_3 formed, it loses its catalytic activity and in a side reaction the NH_4NO_2 decomps. in the usual way into N_2 and H_2O to an extent depending on the time, temp., concn. and catalytic influences. From the earlier work it seemed probable that the above decompn. was to be referred to the undissociated $N_2H_4NO_2$, so that it should decrease with increasing H-ion concn. To det. whether or not such was the case, solns. of $N_2H_4NO_2$ were treated at 10° with 1-6 N HCl, HNO_3 and AcOH and, after the reaction was ended, analyzed for N_2H_4 , HNO_2 and NH_3 , and it was found that, whereas in aq. solns. equiv. amts. of N_2H_4 and HNO_2 disappear, in acids there is always an excess of N_2H_4 left and never any HNO_2 . The amt. of N_2H_4 left does not vary very much with varying concns. of any 1 acid, but varies considerably with different acids. The same is true of the amt. of NH_3 formed, much less being formed in HCl and HNO_3 than in AcOH. The disappearance of the HNO_2 may be explained on the assumption that it reacts with another product, *vis.*, HN_3 , thus: $HNO_2 + HN_3 = N_2 + N_2O + H_2O$ (cf. C. A. 10, 578). To det. whether this decompn. plays a role in the Curtius HN_3 synthesis, equiv. amts. of $2N_2H_4.H_2SO_4$ and NaN_3 in HCl and HNO_3 (in AcOH $N_2H_4.H_2SO_4$ was used) were treated with an equiv. amt. of $NaNO_2$ drop by drop with const. shaking and the resulting solns. analyzed for remaining N_2H_4 and HN_3 , and for NH_3 formed. The results showed that the reaction between HNO_2 and HN_3 is faster than that between HNO_2 and N_2H_4 , even though it would at first sight seem that in the stronger acids (HCl and HNO_3) more N_2H_4 than HN_3 disappears (N_2H_4 remaining in 5.7 and 1.3 N HCl, 67.9 and 63.4%; HN_3 remaining, 72.8 and 76.0%; NH_3 formed, 2.3 and 2.4%); in 3.5 and 0.90 N AcOH, however, the N_2H_4 remaining is 77.4 and 85.4%; HN_3 remaining, 35.0 and 32.7%; NH_3 formed, 10.6 and 11.3%. Rightly to interpret these figures, however, it must be remembered that HN_3 is formed from N_2H_4 and HNO_2 in acid soln. and in strong acids the HN_3 formation is about 95%. Therefore, in the expt. in 15.7 N HCl, of the 32.1% N_2H_4 which has disappeared, about $\frac{95}{100}$, or 30%, has been converted into HN_3 ; so of the original HN_3 , $27.2 + 30 = 57.2\%$ has disappeared instead of 27.2%. In aq. acid soln., then, the reaction between HNO_2 and N_2H_4 takes place according to the 3 following equations: (1) $HNO_2 + N_2H_4 = NH_3 + N_2O + H_2O$; (2) $HNO_2 + N_2H_4 = HN_3 + 2H_2O$; (3) $HNO_2 + HN_3 = N_2 + N_2O + H_2O$. Strong acids favor (2) but the velocity of (3) also increases with increasing H ion concn. To obtain the max. yield of HN_3 , a strongly dissociated acid must be used but its concn. must not be too great. As it is the undissociated $N_2H_4NO_2$ which decomps. according to (1), the concn. of the N_2H_4 salt must not be too great, but an excess of N_2H_4 is desirable to keep down (3) by mass action. Although S. and P. have not attempted to det. the greatest possible yield of HN_3 , they report a series of expts. in which the max. yield (59.6%) was obtained from 27.6 g. N_2H_4Cl (97.6% pure, with 1.52% NH_4Cl) in 400 cc. of 25% H_3PO_4 treated drop by drop with 1.35 g. $NaNO_2$ in 400 cc. H_2O .

CHAS. A. ROUILLER.

Hydrazine and its inorganic derivatives. III. The sulfates of hydrazine, with especial consideration of their double salts. FRITZ SOMMER AND KURT WEISE. Berlin. *Z. anorg. allgem. Chem.* 94, 51-91(1916).—In general, the salt deriv. in which N_2H_4 functions as a mono-acid base are the ones ordinarily obtained, but the reverse is true of the sulfates, $N_2H_4SO_4$ being the ordinary sulfate, and $(N_2H_4)_2SO_4$ being but little known. The monohydrate of the latter compd. is readily obtained in quantity by treat-

ing the former with excess BaCO_3 , removing the excess Ba with H_2SO_4 , evapg. the filtered soln., and cooling, when it seps. as large, flat, birefractive, hexagonal tablets, stable in the air, insol. in EtOH. It is far more sol. in H_2O than either $(\text{NH}_4)_2\text{SO}_4$ or $(\text{N}_2\text{H}_5)_2\text{SO}_4$; following are the soly. detns., expressed as g. $(\text{N}_2\text{H}_5)_2\text{SO}_4$ in 100 g. soln.: 25°, 66.91; 35°, 71.28; 45°, 78.54; 50°, 82.35; 55°, 83.40; 60°, 84.72; a break in the curve corresponds to the transition of the monohydrate to the anhydrous salt, which takes place at 47.30°, as detd. by thermometric and dilatometric measurements. Anhydrous $(\text{N}_2\text{H}_5)_2\text{SO}_4$ forms long, colorless prisms, m. 118.9°. The following double salts were easily obtained by double decompn. and concn. over H_2SO_4 : $\text{Li}_2\text{SO}_4 \cdot (\text{N}_2\text{H}_5)_2\text{SO}_4$, large colorless prisms; $\text{MgSO}_4 \cdot (\text{N}_2\text{H}_5)_2\text{SO}_4 \cdot 4\text{H}_2\text{O}$, clear prisms; $\text{CaSO}_4 \cdot (\text{N}_2\text{H}_5)_2\text{SO}_4$, colorless 4-sided tablets; $(\text{N}_2\text{H}_5)_2\text{Al}(\text{SO}_4)_3 \cdot 12\text{H}_2\text{O}$, large, colorless octahedra, 100 g. satd. soln. at 25° contains 24.266 g.; $(\text{N}_2\text{H}_5)_2\text{Cr}(\text{SO}_4)_3 \cdot 12\text{H}_2\text{O}$, well formed violet octahedra. *Hydrasinealotriquo nickel sulfate*, $\text{Ni}(\text{N}_2\text{H}_4)(\text{H}_2\text{O})_2\text{SO}_4$, was obtained from NiSO_4 and $\text{NiSO}_4 \cdot (\text{N}_2\text{H}_4)_2$ as flat, deep blue, 6-sided tablets, stable in air, insol. in EtOH, loses H_2O above 100°, decompd. by boiling H_2O . The above salts are in general analogous to the ammonium double salts. Double salts of the type $\text{M}^{++}\text{SO}_4 \cdot (\text{N}_2\text{H}_5)_2\text{SO}_4$ have been described in the literature; several of these were prepd. and the conclusion is drawn that they are internal complex

salts of the compn. $\begin{array}{c} \text{NH}_2\text{NH}_2 \\ \diagup \\ \text{M}^{++} \\ \diagdown \\ \text{NH}_2\text{NH}_2 \end{array} \begin{array}{c} \text{SO}_4 \\ \diagdown \\ \text{SO}_4 \end{array}$. $\text{N}_2\text{H}_5\text{SO}_4$ was also prepd. and in general the ob-

servations of Curtius and Jay confirmed. Detns. of the freezing-point lowering showed that, contrary to the observations of previous investigators, $\text{N}_2\text{H}_5\text{SO}_4$ dissociates in soln. into 3 ions, N_2H_5^+ , H^+ and SO_4^- ; this conclusion is confirmed by potential measurements. The soly. of $\text{N}_2\text{H}_5\text{SO}_4$ is greatly decreased by addition of acids; with H_2SO_4 the magnitude of the effect falls off but slightly with increasing concn.; with HCl the soly. is rapidly diminished with small additions, but the effect rapidly falls off; with AcOH the effect is less than with either of the above with small concn., but the slope of the curve remains const. By dissolving $\text{N}_2\text{H}_5\text{SO}_4$ in hot strong H_2SO_4 and cooling, is obtained an acid salt, $\text{N}_2\text{H}_5\text{SO}_4 \cdot \text{H}_2\text{SO}_4$, long, colorless, hygroscopic prisms; and from strong $(\text{NH}_4)_2\text{SO}_4$ solns., $\text{N}_2\text{H}_5\text{SO}_4 \cdot (\text{NH}_4)_2\text{SO}_4$, transparent, colorless crystals.

GEORGE W. MORREY.

Studies on sulfites, thiosulfates and polythionates. III. A. SANDER. *Z. angew. Chem.* 29, I, 11-2, 16(1916); cf. *C. A.* 9, 2042, 2357.—S. has shown that in the reactions between HgCl_2 and the Na and K thiosulfates and polythionates, the HgCl_2 does not act as an oxidizing agent. The reaction that occurs takes place in steps, there being successively formed (1) mercuric thiosulfate or polythionate and (2) HgS . The HgS combines with the excess HgCl_2 to form the complex $\text{Hg}_2\text{S}_2\text{Cl}_2$. These observations support those made by Kessler 67 yrs. ago and controvert those recently advanced by Feld. In detg. the amts. of trithionate and tetrathionate present in a mixt., S. uses an oxidation method by means of which the polythionate in the presence of excess NaOH may be oxidized quant. to sulfate with 0.1 $\text{N H}_2\text{O}_2$ soln. The excess NaOH is then detd. with 0.1 N acid. The number of mols. of NaOH used up depends upon the character of the polythionate. By means of this simple titration method the relative quantities of polythionate present in a mixt. may readily be detd. L. T. FAIRBALL.

Oxides of iron. I. Solid solution in the system $\text{Fe}_3\text{O}_4\text{-Fe}_2\text{O}_3$. R. B. SOSMAN AND J. C. HOSTETTER. *J. Am. Chem. Soc.* 38, 807-33(1916).—The expts. were undertaken as a basis for the study of Fe-bearing silicates at high temps. Measurements of the dissociation pressure of Fe_3O_4 and Fe_2O_3 were made in a special vacuum furnace with a heating tube of Pt-Rh connected to 2 McLeod gages and a Hg manometer

reading to 0.01 mm. Oxides of Fe from various sources were used, and gave practically the same results. Reproducible O pressures can be obtained at a given temp.; equil. is established in a few minutes in the absence of disturbing factors. One of these factors was the reduction of the oxide by Pt, yielding O an alloy of Fe and Pt. Equil. was certainly established in the expts., for the same pressures were attained with rising and falling temps. The oxidation of magnetite gives pressures which are identical with those produced by the dissociation of Fe_2O_3 . The pressure-compn. isotherm for this oxide system at 1200° indicates a continuous solid soln. from Fe_2O_3 to (or very near to) Fe_3O_4 . On account of the opacity of the products it was not possible to show the existence of this solid soln. optically beyond 18% FeO. These results are confirmed by the 1100° isotherm. Over most of the range the pressure of O is between 4 mm. and 1 mm., but it drops rapidly near Fe_3O_4 and rises rapidly near Fe_2O_3 . Since the dissociation results in the formation of a solid soln., the pressure of O and the compn. of the solid phase depend upon the relation of the wt. of the charge to the vol. of the space into which the O dissociates. This accounts for the variety and uncertainty of results heretofore obtained in expts. on the dissociation pressure of Fe_2O_3 .

E. B. MILLARD.

The nomenclature of silicon and boron compounds. A. STOCK. *Ber.* 49, 108-111 (1916).—S. proposes a more flexible nomenclature for the compds. of Si and B than that in present use. It is proposed to designate the hydrides of Si as *silanes*, thus, SiH_4 *monosilane*, Si_2H_6 *disilane*, Si_3H_8 *trisilane*, etc. Further than this it is a natural step to adopt the rules of organic nomenclature, as Si_2H_4 *disilene*, $\text{H}_2\text{Si}:\text{SiH}:\text{SiH}:\text{SiH}_2$ *tetrasiladiene*, etc. Org. compds. in which one or more C atoms are replaced by Si may be designated as "silico" compds.; in case all the C atoms are replaced by Si as "persilico" compds. As, for example, *monosilicopropane* $\text{SiH}_3\text{CH}_2\text{CH}_3$, *persilicopropane* Si_3H_8 . In the case of B compds. similar rules may be applied. "Boro" corresponds to "silico" in compds. similar to the "silico" compds. above.

L. T. FAIRHALL.

Silicon hydrides. I. Hydrides as products of the reaction between magnesium silicide and acids. A. STOCK AND K. SOMIERSKI. *Ber.* 49, 111-57 (1916).—Magnesium silicide was prepd. as a blue cryst. mass dissolving readily in HCl with evolution of gas which was inflammable in contact with air. In this reaction a brownish gray residue is formed which reacts only slowly with the acid, but decomposes quickly on heating, becoming white. From the carefully purified gas several of the silicon hydrides can be sepd. by condensation in liquid air. SiH_4 (b. -112°) can be prepd. in very pure form from the condensation mixt. Si_2H_6 (b. -15°) may be obtained by distn. from the condensed mixt. Careful fractionation failed to reveal the presence of any other hydride between SiH_4 and Si_2H_6 . By fractionally distg. at room temp. the liquid remaining after boiling off the 2 hydrides, SiH_4 and Si_2H_6 , the following hydrides were obtained: *silicon octahydride* Si_8H_8 , *silicon decahydride* Si_4H_{10} , *silicon duodecahydride* Si_3H_{12} and *silicon quatordecahydride* Si_2H_{14} . The authors call these compds. *trisilane*, *tetrasilane*, *pentasilane* and *hexasilane*, resp. (cf. preceding abstract). SiH_4 (m. -185° , d. = 0.68 at this temp.) is a gas having a characteristic odor. It decomposes H_2O , forming SiO_2 and H_2 , but does not visibly react with most reagents. It is somewhat sol. in org. solvents. Si_2H_6 (m. -132.5° , d. as liquid at -25° = 0.686) is a colorless gas having an odor similar to that of SiH_4 . It decomposes H_2O at room temp. and is easily sol. in EtOH , C_6H_6 and CS_2 . Si_3H_8 (m. -117° , d. 0.725) is a colorless liquid inflammable in air. It reacts slowly with H_2O . Si_4H_{10} (m. -93.5° , d. 0.79) is a colorless liquid similar in all its properties to Si_3H_8 . It decomposes at room temp. somewhat quickly. Heat breaks it up into Si and H_2 . Si_4H_{12} and Si_2H_{14} could be obtained in very small quantity only. No other liquid silicon hydrides could be found by the above method of prepn.

L. T. FAIRHALL.

The combinations of selenium with silver. GIOVANNI PELLINI. Univ. Palermo. *Gass. chim. ital.* 45, I, 533-9(1915).—The compds. of Se and Ag have been frequently studied. Naumannite, Ag_2Se occurs in nature and is found as an isomorphous mixt. with Ag_2S as agularite. Berzelius and Margottet obtained Ag_2Se synthetically by passing Se vapors over red hot Ag in a N_2 atm. Berzelius and Fabre obtained it by the action of H_2Se on AgNO_3 and Senderson thus: $4\text{AgNO}_3 + 3\text{Se} + 3\text{H}_2\text{O} \longrightarrow 2\text{Ag}_2\text{Se} + \text{H}_2\text{SeO}_3 + 4\text{HNO}_3$; in the sealed tube, $6\text{AgNO}_3 + 3\text{Se} \longrightarrow 2\text{Ag}_2\text{Se} + \text{Ag}_2\text{SeO}_3 + 3\text{N}_2\text{O}_5$. Rossler (*Z. anorg. chem.* 9, 50(1895)) crystd. Ag_2Se from fused Bi. Berzelius obtained Ag_2Se but Fonzes-Diacon threw doubt on its existence. Puschin (*Compt. rend.* 1907, I, 1726) confirmed the existence of Ag_2Se by e. m. f. detns. in the cell $\text{Ag} \mid \frac{1}{2}\text{N AgNO}_3 \mid \text{AgSe}_2$. By thermal analysis, Rossler (*l. c.*) found that Ag_2Se is formed and that 2 liquid layers are formed, 1 of which contains 8 at. % Se. Friedrich and Leroux (*C. A.* 2, 3329) confirmed this. R. found that the selenide m. $834-50^\circ$ and the other alloys show a liquid miscibility break between 5 and 33.2 atom % Se. Pelabon (*Compt. rend.* 43, 294(1906); *C. A.* 4, 10) found the compd. Ag_2Se (m. 880°) and a complete miscibility of Ag with Ag_2Se with eutectic at 25 atom % at 830° . Pelabon found that for alloys with the compn. Ag_2Se with increasing Se concn. the m. p. drops from 880° to 620° and shows a miscibility break; the upper liquid is pure Se and the lower has the compn. AgSe which Guertler (*Metallographie* 1, 954-6) considers not to be a compd. since it decomp. into Se + Ag_2Se on crystn. Since Quercigh and P. (*C. A.* 5, 1884) found the unstable compd. AgTe in the system Ag-Te it seemed desirable to repeat the complete study of this system. 28 alloys were studied in the usual way. From the m. p. of Se (217°) the m. p. curve rises rapidly to 616° at 4-5 atom % Ag and remains const. up to 52 atom % Ag and then rises rapidly again to 897° at 66.6 atom % Ag. With increasing Ag the m. p. drops to 845° at 67-8 atom % Ag to rise to 890° at 68-9% Ag and then rises gradually to the m. p. of pure Ag. Only one compd., Ag_2Se , is formed without decompn. in a way analogous to the compds. Ag_2S and Ag_2Te . The m. p. of the 3 compds. increases from S to Te (Ag_2S m. 842° ; Ag_2Se m. 897° ; Ag_2Te m. 959°). Se does not form a compd. AgSe with Ag similar to that found for Te. The 3 compds. Ag_2S , Ag_2Se and Ag_2Te are polymorphic enantiotropes; the points of transformation are, respectively, 90° and 179° for Ag_2S and 122° and 138° , resp., for the other 2. Ag_2Se shows a miscibility break in the liquid state with Ag and with Se, similarly with other binary systems S-Sb and perhaps Se-Sn. Ag shows a miscibility break with Ag_2S but it was not possible to study the behavior of mixts. richer in S. Ag_2Te does not show any miscibility breaks with its components. E. J. WITZEMANN.

The electrolysis of an aqueous solution of potassium orthothioantimonite and the constitution of this compound. J. H. MULLER. *Bull. soc. chim.* 19, 3-8(1916).—By means of electrolyses, with and without diaphragms, of aq. solns. of K_2SbS_3 , it is shown that only SbS_3 migrates to the anode, thus making clear the mode of ionization of the salt. H. I. S.

Thermal analysis of the system cuprous chloride-cupric chloride. C. SANDONNI. *Atti r. ist. Veneto* 71, II, 553-9(1911).—S. has applied the method of thermal analysis to a study of the system CuCl - CuCl_2 to det., if possible, the presence of complexes between the 2 salts, such as are known to exist in soln. The mixts. of the 2 salts were fused in Jena glass and maintained in an atm. of dry N. The temp. changes were followed by means of a Pt-(Pt + Rh) thermoelement. It was found that mixts. containing less than 40% CuCl_2 remained entirely unaltered (fusion developed no trace of Cl). On the contrary, mixts. containing more than 40% CuCl_2 lost Cl rapidly. The results of thermal analyses indicate the presence of a complex salt of the compn. $2\text{CuCl} \cdot \text{CuCl}_2$, corresponding to 79.5% CuCl .

L. T. FAIRHALL.

The temperature of decomposition of cupric nitrate. LUIGI ROLLA. Univ. Genoa. *Gass. chim. ital.* 45, I, 444-50(1915).—In the study of the catalytic action of various metallic oxides in the oxidation of gaseous NH_3 it is necessary to establish the mechanism of formation and decompn. of the corresponding nitrates. R. has detd. experimentally and calcd. thermodynamically the temp. at which at atm. pressure the reaction $2\text{CuO} + 4\text{NO}_2 + \text{O}_2 \rightarrow 2\text{Cu}(\text{NO}_3)_2$ takes place. The mixt. of $\text{NO}_2 + \text{O}$ obtained by the decompn. of $\text{Pb}(\text{NO}_3)_2$ was allowed to act at various temps. on CuO . The temp. above which CuO does not increase in wt. under these conditions is the pt. of decompn. of anhydrous $\text{Cu}(\text{NO}_3)_2$. Abs. dry $\text{Pb}(\text{NO}_3)_2$ was heated in a horizontal electric furnace in a Jena tube connected with a large test tube, in an upright electric furnace, by way of a manometer. At 240° a number of duplicate expts. showed a slight retention of N_2O_4 but at 250° the wt. of CuO remained const. at atm. pressure. The temp. of decompn. of nitrates may be calcd. by Nernst's theorem: $\log(P_{\text{NO}_2} \cdot P_{\text{O}_2}) = -(2Q/4.571 T) + \Sigma \nu \cdot 1.75 \log T + \Sigma \nu C$ in which P_{NO_2} and P_{O_2} are the partial pressures of NO_2 and O_2 in atms., Q the heat of reaction in small cal., $\Sigma \nu$ the sum of gaseous mols. that are formed in the reaction and C the chem. const. of this gaseous mol. By substituting the values $\Sigma \nu = 5$ and $\Sigma \nu C = 16$ and reducing $Q/4.571 T = 4.41 \log T + 8.5$ (I) is obtained. The value of Q for $\text{Cu}(\text{NO}_3)_2$ is not known. Thomsen detd. the heat evolved in the reaction: $\text{Cu} + \text{O}_2 + \text{N}_2\text{O}_4 + 6\text{H}_2\text{O}$ as 95590 cal. When to this is added 12900 cal. for the heat of dissociation of N_2O_4 into 2NO_2 and 39700 cal. is subtracted for the reaction the heat of formation of $\text{Cu}(\text{NO}_3)_2 \cdot \text{H}_2\text{O}$ is obtained, which, by subtracting the heat of hydration, will give Q . The heat of hydration was detd. Since $\text{Cu}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ loses HNO_3 easily on dehydrating, R. placed it in a H_2SO_4 desiccator containing fuming HNO_3 for a week, then *in vacuo* over CaO and H_2SO_4 and on analysis found it to be $\text{Cu}(\text{NO}_3)_2 \cdot 0.52\text{H}_2\text{O}$ and another specimen as $\text{Cu}(\text{NO}_3)_2 \cdot 0.36\text{H}_2\text{O}$. From these the heat of soln. of anhydrous $\text{Cu}(\text{NO}_3)_2$ was found to be 9488. The heat of soln. of $\text{Cu}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$ is -10710 cal. So that the heat of hydration of $\text{Cu}(\text{NO}_3)_2$ is $10710 + 9488 = 20198$ cal. And thus $Q = 95590 + 12900 - (39700 + 20198)$ or 47592 cal. Substituting 523 ($= 250^\circ$) for T in (I) Q is found to be 48917. The error between the calcd. and experimental value for Q is 2.6%. E. J. WITZEMANN.

Amphoteric metallic hydroxides. III. Chromium hydroxide. J. K. WOOD AND VERA K. BLACK. Univ. Coll., Dundee. *J. Chem. Soc.* 109, 164-71(1916); cf. C. A. 2, 1650; 4, 2242.—Freshly pptd. and well washed $\text{Cr}(\text{OH})_3$ in solns. of NaOH of varying concns. was maintained at 25° . After 3 wks. only a very small amt. of Cr was found in the most concd. soln., but after 3 months a yellow color began to develop in this soln. and later in all the others, the intensity being roughly proportional to the concn. of alkali. This was proved to be due to oxidation to chromate by air. The authors regard this as evidence for acid properties in $\text{Cr}(\text{OH})_3$. As the curve showing $[\text{NaOH}]$ -[salt] is not a straight line, it must be concluded that $\text{Cr}(\text{OH})_3$ behaves as a polybasic acid. Attempts to det. the hydrolysis of violet solns. of CrCl_3 by catalysis of hydrolysis of MeOAc were unsuccessful. Complex AcOH derivs. of Cr appeared to be formed. Attempts to det. the soly. of the base in HCl of varying concn. were equally without result. A. R. M.

Stannous and lead alkali double halides. F. RIMBACH AND F. FLECK. Bonn. *Z. anorg. allgem. Chem.* 94, 139-56(1916).—Double salts were prepd. at temps. inside their transition interval by crystn. from the incongruently satd. soln. obtained by adding the components in the desired proportions to insufficient H_2O for complete soln. and sepg. the liquid phase in equil. with double salt and 1 component. The transition temp. was detd. by means of soly. detns.; in all cases studied the double salt becomes stable on increase in temp. The transition temp. for $\text{NH}_4\text{SnCl}_4 \cdot \text{H}_2\text{O}$ is about 20° ; from 16° expressed in g. anhydrous salt per 100 g. soln., is represented

by the formula $P = 57.534 + 0.3598t$. The transition temp. of $\text{KSnCl}_4 \cdot \text{H}_2\text{O}$ is below 3.2° ; from 3.2 to 71° , $P = 23.186 + 0.83063t$; the transition temp. of $\text{NH}_4\text{SnBr}_4 \cdot \text{H}_2\text{O}$ is 50° , of $\text{KSnBr}_4 \cdot \text{H}_2\text{O}$, 45° . $(\text{NH}_4)_2\text{SnCl}_4 \cdot \text{H}_2\text{O}$ is stable in contact with H_2O over a large range of temp.; from 1.6 to 79° , $P = 27.479 + 0.5816t$. The transition temp. of $\text{K}_2\text{SnCl}_4 \cdot 2\text{H}_2\text{O}$ is about 35° ; from 35.6 to 77.3 , $P = 26.705 + 0.4829t$. The transition temp. of $(\text{NH}_4)_2\text{SnBr}_4 \cdot \text{H}_2\text{O}$ is 80° . Contrary to statements in the literature, compds. of the type M_2SnCl_6 exist; the following were prepd. by the above method: *Stannous tetraammonium chloride*, $(\text{NH}_4)_4\text{SnCl}_6 \cdot \text{H}_2\text{O}$, transition temp. slightly above 70° ; *stannous tetrapotassium chloride*, transition temp. about 70° ; *stannous tetraammonium bromide*, transition temp. about 92° ; *stannous tetrapotassium bromide*, transition temp. about 70° . *Lead tetraammonium chloride*, $(\text{NH}_4)_4\text{PbCl}_6 \cdot \text{H}_2\text{O}$ was obtained with difficulty; its transition temp. could not be detd. Attempts to prep. similar compds. with KCl and RbCl failed.

GEORGE W. MORRY.

New series of platinum compounds analogous to Cossa's salts. L. CHUGAEV AND V. LEBEDINSKII. Petrograd. *Compt. rend.* 162, 43-5 (1916).—The mother liquors from the action of CH_3CN on K_2PtCl_4 yielded another compd. as sol. as K_2PtCl_4 and like it pptd. by the chloride of Reiset's first base. This compd. was sepd. from the co-pptd. salt of Magnus by extg. with hot water acidulated with HCl . The filtrate on cooling yielded square plates, orange, strikingly resembling the double salt of Cossa, $[\text{Pt}(\text{NH}_3)_4][\text{Pt}(\text{NH}_4\text{Cl})_2]$. Analysis and reactions established that the salt was $[\text{Pt}(\text{NH}_3)_4][\text{PtCl}_4\text{CH}_3\text{CN}]_2$, corresponding to the acid $\text{H}[\text{PtCl}_4\text{CH}_3\text{CN}]$. When heated with HCl the orange salt gives an abundant rose ppt. gradually becoming green; the latter gives all the reactions of the green salt of Magnus; the rose ppt. is the isomeric form described by Jørgensen. Other sol. double salts of the acid $\text{H}[\text{PtCl}_4\text{CH}_3\text{CN}]$ are obtained by treating the double salt with the appropriate chloroplatinite in water slightly acidulated with HCl to avoid hydrolysis. The K salt, $\text{K}[\text{PtCl}_4\text{CH}_3\text{CN}]$, was prepd. It reformed the double salt on addition of the chloride of Reiset's first base; heated with HCl it gives K_2PtCl_4 ; with CH_3CN in neutral soln. it gives the salt of Hofmann and Bugge. The foregoing shows that CH_3CN reacts with sol. chloroplatinites like NH_3 and org. amines.

A. R. MIDDLETON.

Solution of cerium group oxides by certain acids. W. S. CHASE. Cleveland. *J. Ind. Eng. Chem.* 8, 239-40 (1916).—Soln. of these oxides in residues from extrn. of Th from monazite is shown to be much facilitated by addition of small amts. of H_2O_2 . The accelerating effect is equally shown with H_2SO_4 , HNO_3 , or HCl and whether the acids be concd. or quite dilute. AcOH was found unsatisfactory as a solvent and H_2O_2 had no accelerating effect in presence of this acid.

A. R. MIDDLETON.

Gadolinium sodium sulfate. D. W. BISSSELL AND C. JAMES. *J. Am. Chem. Soc.* 38, 873-5 (1916).— Gd material was purified first by crystg. the double Mg nitrates, then the bromates, until the least sol. portion gave a pure white oxide. The bromate was then converted into oxalate, then to sulfate, and recrystd. The soly. in dil. solns. of Na_2SO_4 of this $\text{Gd}_2(\text{SO}_4)_3$ at 25° was then detd. by rotating the solid with the soln. in a thermostat for several months. 100 g. H_2O dissolve 2.15 parts of $\text{Cd}_2(\text{SO}_4)_3$ in the absence of Na_2SO_4 , but the soly. falls off rapidly in the presence of Na_2SO_4 . When the latter salt is present 1.26 g. per 100 g. H_2O the soly. of the Gd compd. is only 0.17; it falls to 0.05 when there are 7.46 g. Na_2SO_4 per 100 g. H_2O and then remains const. as the Na_2SO_4 is further increased. There is probably only one compd. formed between these 2 salts, namely $\text{Gd}_2(\text{SO}_4)_3 \cdot \text{Na}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$, similar to the K compd. of Benedict (1899).

E. B. MILLARD.

Extraction of beryllium from gadolinite. C. JAMES AND G. A. PERLEY. *J. Am. Chem. Soc.* 38, 875-7 (1916).—Finely powdered gadolinite was treated with hot H_2SO_4

until dense white fumes were evolved. The soln. was allowed to settle until silica, etc., had sepd., then siphoned off and treated with hot $\text{H}_2\text{C}_2\text{O}_4$ and allowed to stand 12 hrs. After filtering, KBrO_3 was added to oxidize the $\text{H}_2\text{C}_2\text{O}_4$ and the Fe and Be were pptd. together by adding first a small quantity of NH_4OH , then NaOH until the odor of NH_3 was quite strong. Enough H_2SO_4 or HCl was added to the ppt. to dissolve about $\frac{2}{3}$ of it, and then NaOH was slowly added until a small portion of the filtered liquid gave a light colored ppt. with NH_3 , showing that most of the Fe was pptd. After removing the small amt. of Fe remaining, the Be was pptd. as basic carbonate with Na_2CO_3 . If the material is very rich in Be, the first complete pptn. with NaOH may be omitted and a partial pptn. carried out after removing the rare earths and oxidizing the Fe. The sepn. of Be and Al will be described in a future paper. E. B. M.

Beryllium nitride. FR. FICHTER AND EMIL BRUNNER. Basel. *Z. anorg. allgem. Chem.* 93, 84-94(1915).—Impure Be was prepd. by electrolysis of a molten mixt. of BeF_2 and NaF ; it was purified by pressing into cylinders and heating to 1450° in an atm. of H, when the pure metal oozed out of the cylinder in drops. The cylinder was supported on a MgO or an Al_2O_3 support; if the temp. was raised to 1900° the Be reacted with the MgO , and the Mg condensed in a cooler portion of the tube. At 153° in a H atm. at 5 mm. pressure, Be loses weight by volatilization to the extent of $\frac{1}{2}$, its weight in 30 min. Heated in N, or better, in NH_3 to 1000° , Be takes up N with formation of Be_3N_2 ; no compd. containing both N and H appears to be formed. Be_3N_2 sublimes readily; heated rapidly in N it melts at 2200° , and dissociates at a slightly higher temp. Be_2C reacts rapidly at 1000° with NH_3 or at 1250° with N with formation of Be_3N_2 and sepn. of C; a mixt. of BeO and C does not react until about 1900° .

GEORGE W. MORREY.

Isomorphism between sodium nitrate and potassium nitrate (AMADORI) 2. Properties of silicates of the system $2\text{FeO} \cdot \text{SiO}_2 + 2\text{CaO} \cdot \text{SiO}_2$ (SÉLIVANOV) 9.

7. ANALYTICAL CHEMISTRY.

E. G. R. ARDAGH.

Simplified quantitative micro-elementary analysis of organic substances. J. V. DUBSKY. Zürich. *Chem. Ztg.* 40, 201-3(1916).—D. claims to have so simplified and improved Pregl's methods (*C. A.* 9, 1730) that micro-analyses may be made by anyone experienced in macro-analysis. The app. for the detn. of N, C and H is described, with cuts, and detailed directions for operating are given. The app. and manipulation are substantially the same as P.'s.

J. H. MOORE.

Succinic acid as a standard. C. A. PETERS AND V. SAUCHELLI. *Am. J. Sci.* 41, 244-8(1916).—The authors were unable to duplicate the work of Phelps and Hubbard (*C. A.* 1, 1832) who found that succinic acid might be used as a standard for volumetric work against NH_4OH with cochineal as an indicator. In parallel detns. using (1) the electro-titrametric method of Suchtelen and Stano (cf. *C. A.* 8, 3400), (2) the HCl titration with Me orange as indicator, and (3) the method of Phelps and Hubbard, they obtained for the normality of a soln. of NH_4OH the values 0.1240, 0.1224 and 0.1313, resp.

H. L. OLIN.

Reagents for use in gas analysis. IV. Phosphorus in solution. R. P. ANDERSON AND W. BIEDERMAN. *J. Ind. Eng. Chem.* 8, 135-6(1916).—In the abstract of this paper appearing in *C. A.* 10, 728 the second author's name was omitted through an error.

E. J. C.

Color standards and colorimetric assays. H. V. ARNY AND C. H. RING. *J. Ind. Eng. Chem.* 8, 309-17(1916).—Practically every tint desired in colorimetric work can be obtained from either the "Co-Fe-Cu," the "Co-Cro-Cu," or the "Cro-manganate" blends. (Cf. *C. A.* 8, 2540; 9, 2492; 10, 804.) The following detns. are dealt with in detail: NH_3 (Nessler), nitrates, nitrites, vanillin, uric acid, salicylic acid and phosphates. H. M. LANCASTER.

A simple and rapid assay of lead. G. TOROSSIAN. *J. Ind. Eng. Chem.* 8, 331 (1916).—By the action of Al and HCl, the Pb in many compds. is reduced to metallic Pb, which may be dried and weighed. Results obtained in 9 detns. of Pb in $\text{Pb}(\text{OAc})_2$ varying from 54.19 to 55.26% (theoretical, 54.61%), show the method to be suited to those requiring rapid and approx. detns. H. M. LANCASTER.

The reduction of pentavalent to trivalent arsenic by cuprous chloride and the determination of arsenic by distillation as arsenic trichloride. R. C. ROARK AND C. C. McDONNELL. *J. Ind. Eng. Chem.* 8, 327-31(1916).—Ferrous salts effect only incomplete reduction of As^{V} to As^{III} in HCl solns. Apparent contradictions of this statement have arisen from (a) Cu or Cu salts present as impurities, CuCl being formed. (b) As present in small amts., (c) As present as the free metal, or as arsenite and not as arsenate. In HCl solns. CuCl effectively reduces As^{V} to As^{III} , and the AsCl_3 is completely sepd. from Sb, Pb, Cu, Zn, Fe and Ca by distn. H. M. LANCASTER.

The general applicability of the paper pulp filter to quantitative analysis. S. J. JODIDI AND E. H. KELLOGG. *J. Ind. Eng. Chem.* 8, 317-9(1916); cf. *C. A.* 10, 730.—In the quant. manipulation of BaSO_4 , AgCl , K_2PtCl_6 and $(\text{NH}_4)_2\text{PtCl}_6$ considerable time and labor can be saved by the use of paper pulp. The results are as accurate as those obtained with standard filter paper. H. M. LANCASTER.

An accurate end point in the volumetric determination of sulfur in steel. H. ZSCHIEGNER. *J. Ind. Eng. Chem.* 8, 324(1916).—In titrating H_2S with I and starch, the end point is sharp, and results do not vary more than 0.001%, if use is made of a special titrating vessel consisting of a white porcelain beaker 7 cm. in diam. $\times$ 16 cm. deep with a thin disk of hard black rubber or celluloid, 2 cm. diam. cemented to the inside of the bottom. An ordinary beaker, covered on the outside with black and white enamels, is a satisfactory substitute. H. M. LANCASTER.

Determination of sulfur in zinc blende. H. KOELSCH. *Chem. Ztg.* 40, 174 (1916).—Fuse 0.625 g. blende or 1.25 g. roasted blende with 15 g. Na_2O_2 in a 25 cc. Fe crucible over a strong flame, swirling carefully in the flame after fusion begins till it ends, put the slightly warm crucible in 150 cc. H_2O in a 300 cc. beaker, cover, let the contents dissolve, wash the crucible, transfer the soln. and the insol. residue to a 250 cc. flask, add 10 cc. concd. HCl, cool, fill, filter through a dry filter, acidify 200 cc. with HCl and ppt. S with BaCl_2 . It is not necessary to remove Fe from the soln. before pptg. for control work. The results check with those by fusing with $\text{Na}_2\text{CO}_3\text{-KClO}_3$ mixt. J. H. MOORE.

The reduction test for tungsten. M. L. HARTMANN. *Pahasapa Quart. (S. Dak. School of Mines)* 5, 23-6(1916).—W minerals fused with Na_2CO_3 give sol. Na_2WO_4 which when acidified with HCl or H_2SO_4 in the cold yields a white flocculent ppt. varying in compn. from $\text{WO}(\text{OH})_4$ to $\text{WO}_2(\text{OH})_2$. On ignition this yields the yellow oxide WO_3 , which on the addition of strong reducing agents becomes bright blue by the formation of a suspension of lower oxides—a qualitative test for W. As a result of his study of the method H. recommends the following procedure: Boil 0.2 g. of the ore with HCl (d. 1.20) until one-half the acid is evaporated. Dil. with an equal vol. of H_2O , add a piece of metallic Sn and heat. If this test fails to produce the blue color, fuse a 0.5 g. sample with 4 g. Na_2CO_3 , take up the mass with boiling H_2O in the crucible, add

an equal vol. of HCl and proceed as before. The method is applicable to material with 2% W or less.

H. L. OLIN.

Determination of carbon in steels and irons by direct combustion in oxygen at high temperatures. J. R. CAIN AND H. E. CLEAVES. Bur. Standards, *Tech. Paper* 69, 10 pp.(1916).—An amplification of a preliminary paper by the same authors (cf. C. A. 8, 3403). A method has been devised for the detn. of C in steels and irons by direct combustion in O at 950 to 1100°, finishing above 1450°, so that the Fe oxides are kept fused for several mins., in order to give the best possible chance for liberating all the C. This method was tested by analyzing various types of plain C and alloy steel standards of the Bureau and some of the pig-Fe standards, the C results obtained averaging about 0.01% above the certificate analysis.

F. W. SMITHER.

Rapid method for the estimation of copper and iron. GRAHAM EDGAR. *J. Am. Chem. Soc.* 38, 884-7(1916).—The method is a modification of the Volhard method (*Z. anal. Chem.* 18, 285(1879)), and is based on the following steps: (1) Cu is pptd. as CuSCN and Fe reduced to the ferrous state by the action of SO₂ and standard NH₄SCN soln., (2) excess SO₂ is removed by boiling in a current of CO₂. The soln. is cooled and filtered, (3) the filtrate is treated with an excess of standard AgNO₃ soln. and is then titrated for Fe with KMnO₄ soln., (4) Cu is detd. by titrating the excess Ag in the soln. with NH₄SCN. Details are given for the process.

E. B. MILLARD.

Some qualitative tests for gum arabic and its quantitative determination. C. E. WATERS AND J. B. TUTTLE. Bur. Standards, *Tech. Paper* No. 67, 15 pp.(1916).—The object of this paper is to bring together the most important methods that have been published, with more or less discussion of each, and to present a new procedure for the detn. of gum arabic. It was found that Pb(OAc)₂.PbO gives the most characteristic reaction. Mixts. of neutral FeCl₃ and alc., and of CuSO₄ and NaOH are of value as confirmatory tests. Dextrin and gum ghatti, which is in many respects similar to gum arabic, behave toward these reagents quite differently from the latter gum and from one another. Heating with KOH, color reactions with phenols and a number of other reagents were found to give indications of no value. After numerous trials of CuSO₄ and alkali, as well as of modifications of Fehling soln., W. and T. propose the following as a satisfactory quant. method: Dissolve 50 g. of Cu(OAc)₂ in H₂O, add an excess of NH₄OH and dil. to 1 l. using H₂O and alc. in such proportions that the final soln. contains 50% of alc. For each detn. pipet 50 cc. of the gum arabic soln. (=0.25 g. gum) into a 250-cc. beaker, add 50 cc. of alc., and then 25 cc. of the Cu reagent, with const. stirring. Let the ppt. settle, filter on a tared paper, wash with 50% alc. containing NH₄OH, then with 75%, and finally 95% alc.; dry to const. wt. at 105°, ignite in a porcelain crucible, and weigh the ash. The amt. of ash deducted from the wt. of the original ppt. gives the "net gum arabic." The amt. of moisture in the gum originally taken for analysis must be allowed for, and is detd. by drying in a current of H at 105°. The percentages of gum found in a series of 18 detns. averaged 99.5%, the extreme values being 96.6 and 103.3%.

F. W. SMITHER.

Investigation of the antimony spot. Its behavior towards hypochlorite. W. VAUBEL AND A. KNOCKE. Darmstadt. *Chem. Ztg.* 40, 209-10(1916).—In the hypochlorite test to distinguish between As and Sb in spots from the Marsh app. the Sb spot is sometimes dissolved. To det. the cause of this, tests were made on spots from tartar emetic; it was found that while fresh solns. of NaOCl, KOCl and Ca(OCl)₂ did not dissolve the spots they were quickly dissolved by an old hypochlorite soln. Expts. showed that this was due to the presence of NaClO₂ in the old soln., formed by the reaction $2\text{NaOCl} + \text{H}_2\text{O} \rightarrow \text{NaClO}_2 + \text{NaCl}$, but that when the old soln. of sp. gr. 1.052 was diluted with water the reaction was very slight. Old Sb spots were not dissolved even

by the old soln. An examn. of the Sb deposit made by heating the exit tube of the Marsh app. showed it to consist of (1) steel gray metallic Sb, insol. in old hypochlorite soln.; (2) velvet black Sb mirror, probably SbH_3 or Sb in monomolecular form, sol. in old soln. Spots on the porcelain dish consist of (3) a light gray deposit, apparently Sb_2O_3 , perhaps also Sb_2O_3 , sol. in HCl ; (4) a deposit identical with (2); (5) a brownish black portion resembling the As spot, sol. in HCl but insol., or only very slightly sol. in the old soln., probably an allotropic modification of Sb; (6) gray streaks, apparently metallic Sb. Spots on the dish disappear more or less completely on standing a few days, the constituent (5) being most persistent, thus explaining the insolubility of old Sb spots even in the old soln. Hence only fresh hypochlorite solns. should be used in making this test. J. H. MOORE.

Reappearance of the blue color in iodine titrations. H. DUBOVIČ. *Kv. Magyar Természettudományi társulat, Budapest*, Mar. 13, 1915; *Chem. Ztg.* 39, 585(1915).—An address in which the causes of the reappearance of the blue color in I titrations are discussed. The most frequent cause is the presence of NO_2 either in the air or in the water. Another cause is the presence of free or combined Br, which reacts more slowly on $\text{Na}_2\text{S}_2\text{O}_3$ than I and in a different manner. Finally, very small amts. of I react on starch not instantaneously, but after some time. E. H.

8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

EDGAR T. WHERRY.

Bibliography of North American geology for 1911. JOHN M. NICKLES. U. S. Geol. Survey, *Bull.* 524, 162 pp.(1912); for 1912, *Bull.* 545, 192 pp.(1913); for 1913, *Bull.* 584, 183 pp.(1914); for 1914, *Bull.* 617, 167 pp.(1915); cf. *C. A.* 6, 53.—This series of bulletins contains author and subject indexes, with brief abstracts, of publications on geology and related subjects, including mineralogical and geological chem. Lists of analyses of minerals and rocks appearing in these publications are given. E. T. W.

Diffusion between crystals in the solid state at ordinary temperatures and its importance in mineral formation. F. QUERCIGH. *Rend. accad. sci. fis. nat. Napoli* [5] 21, 18-9(1915).—It was shown that even at ordinary temps. there is a marked diffusion between crystals in the solid state with the formation of a simple [isomorphous] solid soln. The diffusion of iodyrite in miersite and in marshite, and of HgBr_2 into HgCl_2 were studied. In this way an example of a new method of mineral synthesis was demonstrated: i. e., synthesis by simple diffusion in the solid state. The photomicrographs show this effect clearly. E. J. WITZEMANN.

A peculiar intergrowth of phosphate and silicate minerals. EDGAR T. WHERRY. U. S. Nat. Museum. *J. Wash. Acad. Sci.* 6, 105-8(1916).—A green and white substance associated with variscite in fissure veins in metamorphosed slate near Manhattan, Nevada, consists of a green glassy mass, traversed by numerous sub-parallel wavy white lamellas, varying from 1 to less than 0.05 mm. in thickness. Both minerals are amorphous, showing only traces of doubly refracting material. Analysis by J. E. Whitfield of as pure a specimen of the green material as could be obtained by hand picking, but containing sub-microscopic white lamellas, gave: CaO 6.30, CuO 1.25, MgO 0.80, Al_2O_3 25.90, Fe_2O_3 2.14, P_2O_5 24.76, SiO_2 7.32, H_2O below 100° 21.90, above 100° 9.20, sum 99.57. A small sample of the white lamellas containing perhaps $1/3$ of its wt. of green material was analyzed by E. T. W. with the following results: $\text{CaO} + \text{CuO}$ 9.0, $\text{Al}_2\text{O}_3 + \text{Fe}_2\text{O}_3$ 23.3, MgO 0.5, P_2O_5 12.1, SiO_2 30.0, H_2O below 100° 10.4, above 100° 14.8, sum 100.1. On comparison with the known Al phosphate minerals the former

was found to resemble vashegyite most closely, and is probably an impure form of that species. The white mineral is a zeolite related to laubanite, but amorphous. "The material studied is regarded as a colloidal vashegyite traversed by rhythmically pptd. laminae of a Ca-Al silicate of probably zeolitic nature." L. W. RIGGS.

Some mining districts in northeastern California and northwestern Nevada. JAMES M. HELL. U. S. Geol. Survey, *Bull.* 594, 200 pp.(1915).—Includes discussions of the origins of deposits of Au, Ag-Pb, Cu and Sb ores. E. T. W.

Geology and mineral resources of the Kenai Peninsula, Alaska. G. C. MARTIN, B. L. JOHNSON AND U. S. GRANT. U. S. Geol. Survey, *Bull.* 587, 243 pp.(1915).—This bulletin includes descriptions of beds of coal, with analyses, and of deposits of Au, Ag, Cu and minor metals. The origin of some of these deposits is discussed. E. T. W.

Gold quartz replacements in intrusive rock. J. F. McLENNAN. *Mining Eng. World* 44, 389-92(1916).—M. describes the geology and topography of the northern Sierra Nevada and Klamath Mountains. As a typical example is chosen the region of the Feather River. It is pointed out how the dikes and sheets which course the Paleozoic slate undergo variable changes commensurable with the scope of rock subdivision and mineralogical make-up. Thus the more fractured and permeable (Leucophyre vs. Diorite) rock is more readily affected by the "twofold results of circulating solns.; rock alteration, and later, after the descending waters becoming chemically effective through properties collected in their descent, complete reduction of the invaded rock and through substitution, laying down mineral substances collected in their travels." These replacements are not uniform in compn., varying from Au-bearing quartz, to worthless quartz, to sulfides or sulf-arsenides. C. BRAMSON.

Cambrian manganese deposits of Conception and Trinity Bays, Newfoundland. N. C. DALE. Princeton Univ. *Proc. Am. Phil. Soc.* 54, 371-456(1915).—The general geographic and geologic relations of the Mn deposits of S. E. Newfoundland are described, and detailed descriptions of these localities are given, as well as of other Mn deposits of somewhat similar character in Wales, Saxony and Arkansas. Recalcd. analyses are shown in the following table, in which A to K represent Newfoundland specimens, and L to N samples from Elbingerode, Saxony. (G and H, not being Mn ores, are omitted.)

	MnCO ₃	MnSiO ₃	MnO ₂	CaCO ₃	MgCO ₃	Ca-(PO ₄) ₂	SiO ₂	Fe ₂ O ₃	BaSO ₄	H ₂ O	Clay	Total
A.....	44.39		8.08	20.11	4.21			3.36		0.86	18.24	99.2

N.....	76.13	8.92		4.00	2.44		2.16	0.37			5.98	100.00

These analyses are discussed at length and the genesis of the Mn ores summarized as follows: The ultimate source of the Mn was the Mn-bearing silicates of pre-Cambrian igneous and metamorphic rocks east and west of the Cambrian sea. The Mn-bearing silicates went into soln. as sol. bicarbonates, which under favorable conditions were oxidized to oxides. The Mn was transported chiefly as bicarbonate, and to a less ex-

tent as suspended particles of oxides, by pre-Cambrian drainage systems to Cambrian basins. A concn. of the salts of Mn in the sea water immediately overlying the deposited muds, and the liberation of CO_2 , caused a pptn. of MnCO_3 or Mn oxides. "While the main contribution of the Mn came from the pre-Cambrian drainage area in soln., undoubtedly the deposited muds supplied a minor portion." L. W. RIGGS.

High grade manganese ores of Brazil. J. T. SINGEWALD, JR. AND B. L. MILLER. *Iron Age* 97, 417-20(1916).—The geology and history of the manganese deposits in Brazil are given and their importance in the industries pointed out. Detailed descriptions of a few districts are given, and mention is made of the cost of mining, av. analysis, output, and shipment facilities. C. BRAMSON.

Pebble phosphates of Florida. E. H. SELLARDS. *Flo. State Geol. Surv., Ann. rept.* 7, 29-116(1915); *Am. J. Sci.* 41, 299(1916).—A geologic study of the origins of the pebble phosphates. The variation of the thickness and continuity of the deposits is attributed to the irregularity of the erosion surface upon which the pebbles were deposited, and to the constantly changing depth of water and force of wave action of the advancing sea. The variation in phosphate content appears to result from the irregular sorting action of the water, from varying phosphate content of the supply and from secondary enrichment being more complete in some places than in others. L. W. RIGGS.

Geology and coal resources of North Park, Colorado. A. L. BEEKLY. U. S. Geol. Survey, *Bull.* 596, 121 pp.(1915).—Analyses of samples of the coals of this region from 7 different mines are tabulated. The coal is to be classed as subbituminous E. T. W.

Summation of chemical analyses of igneous rocks. H. H. ROBINSON. Peabody Museum, New Haven. *Am. J. Sci.* 41, 257-75(1916).—The object of this paper was to discuss the subject of summation in a general way as well as in individual cases, and to det. if the departures from the mean value were distributed in any definite and orderly manner. The 3391 analyses of the Washington and Washington-Roth tables formed a basis of study. For details the original article should be consulted. L. W. R.

Petrographic description of several basalts from Patagonia, western Antarctica and the southern Sandwich Islands. OLOF BÄCKSTRÖM. *Bull. Geol. Inst. Univ. Upsala* 13, 115-82(1915).—A large number of specimens are described, analyses being given. The classifications of the rocks in the Osann and C. I. P. W. systems are worked out, and their relations discussed. E. T. W.

Analysis of slate and dike. E. E. WHITE. *Eng. Mining J.* 101, 433-4(1916).—Since it is often impossible to differentiate between the slate and dike in hand specimens, as well as in thin sections, W. has analyzed a number of known slates and known dikes of the Marquette Range, using the results to build up a table of limiting values and factors. The dikes are characterized by high ignition loss, high ratio of Fe^{+} to total Fe, and low insol. residue + Fe oxides. The slates are characterized by low ignition loss, low ratio of Fe^{+} to total Fe, and high insol. residue + Fe oxides. If any one of these 3 factors indicates a different material from the other 2, the sample is considered indeterminate (this occurred in only 3 samples out of 83 analyzed). Insol. residue is detd. by digesting with HCl and evapg. to dryness twice, then adding more HCl, filtering, washing, igniting, and weighing the residue. Tables are given showing results of analysis of 83 samples. Each mine or locality must be taken as a unit and new tables of limits prepd. by analyzing known samples, as the limits reported apply only to the Marquette Range. F. W. SMITH.

Weathering in the podzol

Northland (T)

9. METALLURGY AND METALLOGRAPHY.

WILLIAM BRADY, WILLIAM T. HALL.

Aluminium dust. G. H. CLEVINGER. *Mining Sci. Press* 112, 118(1916).—A representative analysis of a good grade of Al dust is: Al 91.20, Al_2O_3 5.80, SiO_2 1.30, Si 0.40, C 0.23, H_2O 1.07%. N may also be present. Al dust is used chiefly in the cyanide process, in thermite welding and in explosives. L. P. WEBBERT.

Calculations with reference to the use of carbon in modern American blast furnaces. HENRY P. HOWLAND. *Bull. Am. Inst. Mining Eng.* 1916, 627-50.—H. describes methods for calcg. the % C gasified at the tuyères, the vol. of air consumed per unit of coke, and the relation between air, coke, and Fe output, and also for analyzing the work done by the C in the furnace with a view to answering the question of causes of high and low coke consumption. He concludes that the explanation does not lie in differences in the % C gasified at the tuyères, in differences in the air-coke ratio, nor in C contents of the coke, but in variations in coke quality which det. the speed of oxidation at the tuyères. A quickly burning coke made from coal low in ash and high in volatile matter allows a max. concn. of heat in the hearth, which is consistent with high efficiency in fuel consumption. Concn. of heat is further effected by low wind velocity and large hearth area. H. L. OLIN.

Modern American blast-furnace practice. R. V. MCKAY. *Year Book Am. Iron and Steel Inst.* 1914, 85-101.—A detailed account with tables, curves, analytical data, etc., of the various steps followed in obtaining the present very satisfactory results in smelting Mayari (Cuban) ore. F. W. SMITHER.

Modern American blast furnace practice. E. S. COOK. *Year Book Am. Iron and Steel Inst.* 1914, 102-11.—A review of the development of the lines of the modern blast furnace of the East, as illustrated by Warwick furnace No. 2 at Pottstown, Pa. C. sums up as follows: (1) The Edgar Thomason furnace, which did the best work about 1900, using Lake Superior ores and making steel works Fe, proved the most satisfactory furnace at that time for using the various ores of the East on merchant grades of Fe. (2) The development in the East has been along the lines of larger hearths and lower boshes, the same as the development in the West. Somewhat steeper boshes seem desirable. (3) The large furnace, which at first was thought only suitable for making basic Fe, has since been found to make all the grades of merchant Fe (foundry, Bessemer, malleable, and low P) of a satisfactory quality, and with as low fuel consumption as the small furnace. (4) Various difficult materials can be used up to a certain percentage and good work and long life can be got out of a furnace, provided care is taken to see that the stock distribution and the air distribution are correct, and attention given to proper uniformity of operation. F. W. SMITHER.

Modern American blast-furnace practice. H. A. BRASSERT. *Year Book Am. Iron and Steel Inst.* 1914, 15-69; cf. *C. A.* 8, 2864.—A comprehensive review and discussion with drawings, curves, tables, analytical data, etc. Results obtained at the South Works of the Ill. Steel Co. and at Gary are reported. F. W. SMITHER.

Modern American blast-furnace practice. A. J. BOYNTON. *Year Book Am. Iron and Steel Inst.* 1914, 76-84.—A discussion of a paper by Brassert (cf. preceding abstract), and of results obtained at Lorain, O. F. W. SMITHER.

Treatment of blast-furnace flue dust. B. G. KLUGH. *Year Book Am. Iron and Steel Inst.* 1913, 335-48; cuts.—A study of the microscopic structure of the products of the various processes. "A comparison of the products of the various processes in favor of the process employing the least degree of heat-agglomerated material is the constituent of heat-agglomerated ma-

terials which retards the reducibility of such products by enveloping the Fe oxide and hermetically sealing it against the action of the furnace gases. The presence of this objectionable constituent is due to the high temp. employed in the agglomerating process. Agglomeration may be effected at such temps. and with such control of the time element as to produce an agglomerate entirely free from this silicate. Where the latter conditions are attained, the incident porosity of the product, consisting of intercommunicating channels from $\frac{1}{4}$ -in. down to microscopic size, contributes materially to the ideal reducing requirements of the blast-furnace material. An agglomerate which embodies the characteristics of freedom from the sealing constituents of fused silicates and at the same time has a permeability allowing free action of the gases on an infinitely large area is essentially one of max. reducibility and hence of greatest value as a blast-furnace stock."

F. W. SMITHER.

Treatment of blast-furnace flue dust. E. B. CLARK. *Year Book Am. Iron and Steel Inst.* 1913, 314-26.—A review and discussion of processes. F. W. S.

Treatment of blast-furnace flue dust. J. W. DOUGHERTY. *Year Book Am. Iron and Steel Inst.* 1913, 327-34.—A discussion of a paper by Clark (cf. preceding abstract), together with a suggested new method (explained with illustrations) for utilizing flue dust. F. W. SMITHER.

The operation of the blast furnace. J. E. JOHNSON, JR. *Met. Chem. Eng.* 14, 266-8(1916); cf. C. A. 10, 876.—J. gives curves indicating the progressive changes in compn., temp., and pressure of the ascending gas column based on data gathered from the work of various observers. H. L. OLIN.

The use of titaniferous ore in the blast furnace. F. E. BACHMAN. *Year Book Am. Iron and Steel Inst.* 1914, 371-419.—A detailed account of preliminary expts. and of exptl. runs made in the blast furnace at Port Henry, N. Y., using concentrates from the titaniferous ore of Essex Co., N. Y. Drawings photomicrographs, curves, analyses, and tests are given in detail. B. concludes that: Titaniferous concentrates are reduced in the furnace with no greater and probably with less expenditure of heat, and consequently of fuel, than non-titaniferous magnetites, and as a greater proportion of their O is removed by the action of CO than is the case with non-titaniferous magnetites, a lower fuel consumption for the reduction of the Fe may be expected. The slower driving of the furnace for the same wind blown seems to be explicable only on the assumption that more C was burned in the hearth and less in the upper portions of the furnace. With proper concn. Sandford ore should be produced containing Fe from 58 to 60%, and from 9 to 10% TiO_2 . The wt. of slag produced per ton of Fe from an ore of this compn. will be slightly greater than that produced from the av. magnetic concentrate containing 62 to 63% Fe. This additional slag production will about counterbalance the reduced fuel consumption necessary for the reduction of their Fe contents. The slags produced will be of much greater fluidity than those produced when TiO_2 is not present. The operation of the furnace above the tuyère level will be more uniform and there will be less tendency to hang and slip. The Fe produced will contain less S, its Si content will be lower by an amt. equal to 0.5 of the Ti content. With TiO_2 in the slag in excess of 6% the production of high Si iron (Fe containing over 2% Si) will be more difficult. The titaniferous ore being low in SiO_2 is not adapted for the production of high-Si iron. At least until further investigation is made, there is likely to be a tendency to periodical "dirty hearth" conditions in the working of the ore, but they are readily stopped by the removal of titaniferous ore from the mixt. for short periods. F. W. SMITHER.

Laboratory method for determining the capacities of slime-settling tanks. H. S. COE AND G. H. CLEVENGER. *Bull. Am. Inst. Mining Eng.* 1916, 597-625.—In

slime settling 4 distinct zones are recognized, *vis.*, (D) that portion of the pulp wherein the flocs have settled so that they rest upon one another; (C) the transition zone in which the percentage of solids decreases from the bottom where the flocs enter zone (D), to zone (B) where the consistency of the flocculated pulp is the same, as that of the original pulp; and (A) the zone of clear water or soln. The critical settling point is the top of zone (D) just as zone (C) disappears. For calcg. the capacity of a layer of flocculated pulp of any consistency to discharge its solids, the authors propose the formula $C = KR/(F - D)$, where C = capacity in lbs. of solids per sq. ft. per hr., R = rate of settling in feet per hr., F = ratio of fluid to solids in the pulp tested, D = ratio of fluid to solids in the discharge required, and $K = 62.35$, wt. of 1 cu. ft. of water in lbs. The max. capacity of a continuous thickener is, therefore, equal to the minimum value of C for any of its zones. Comparative tests made on vessels 1 to 10 feet deep showed that the critical point is first reached by the surface of the pulp in the most shallow vessel but that the rates of settling in layers of like consistency are the same for vessels of all depths. The tank area A required for thickening 1 ton of solids per day is found by applying the formula $A = 2000(F - D)/24KR$, where D is the fluid-solid ratio in the thickest pulp that can be economically obtained. To find the required depth compute the capacity of the thickening zone which is to contain a supply of solids equal to the total capacity of the tank for the time required to thicken the pulp to the density required in the discharge, add an allowance for the lost space due to the pitch of the drag in the thickener and in addition 2-3 feet for depth of feed and for storage capacity.

H. L. OLIN.

The Liberty Bell methods of precipitate refining. A. J. WEINIG. *Bull. Am. Inst. Mining Eng.* 1916, 651-62.—The cyanide ppt. from this plant varies widely in compn. and its purification requires special care. The method pursued embodies the principle of the addition of an oxidizer and the proper proportionment of fluxes, MnO_2 , KNO_3 , $NaNO_3$, Na_2CO_3 , SiO_2 and $Na_2B_4O_7$, to carry off the oxidized impurities as metallic bases in a fluid slag. The ppt. from the press is mixed with the computed flux while wet, loaded into cast-iron pans, and heated to redness in a cast-iron muffle furnace. The sintered mass makes an excellent charge for crucible melting and a rate of 1300 oz. bullion per hr. with a 65% Au-Ag ppt. is common.

H. L. OLIN.

Cyanidation of flotation concentrate. E. M. HAMILTON. *Mining Sci. Press* 112, 365-6(1916).—H. reports a lab. test on a Calif. Au ore assaying 0.57 oz. Au and a little Ag. The ore was ground to pass an 80-mesh sieve for flotation and yielded a concentrate assaying 9.66 oz. Au and 9.85 oz. Ag. A sample of this concentrate, without filtering or regrinding, was treated by bottle agitation for 72 hrs. with cyanide soln. at 0.2% KCN and at a ratio of 5:1. No preliminary treatment of any kind was given and no reagents were added except CaO and NaCN; the soln. was not changed during treatment, and at the conclusion of agitation the sample was filtered and washed on the filter in the usual way. Extraction: Au, 97%; Ag, 64%. H. believes that given an ore that presents no *a priori* obstacle to cyanidation, the concentrate recovered therefrom by flotation will give no more difficulty in cyanidation than a concentrate from the same ore recovered by any other means.

F. W. SMITHER.

Universal flotation theory. C. T. DURELL. *Met. Chem. Eng.* 14, 251-6(1916).—A discussion of the principles underlying various processes of flotation, including the Delpat, the Minerals Separation, the De Bavay, the Callow, and the liquid-jet types. All processes and kinds of flotation may be satisfactorily explained by gas occlusion. Although oil aids flotation (1) by increasing the surface tension, (2) by decreasing the adhesive force of water for metallic particles by forming films around them and (3) by increasing the cohesive force of particles for each other by means of the film, there is no universal theory that considers oil necessary.

H. L. OLIN.

Flotation concentration at Anaconda, Mont. FREDERICK LAIST AND ALBERT E. WIGGIN. *Bull. Am. Inst. Mining Eng.* 1916, 549-81.—Flotation treatment of slime and mill tailing was tested on a large scale at the Washoe plant with the use of a standard-type Minerals Separation machine treating round table feed. The following agents were used either alone or in combinations: turpentine, crude oil, cresylic acid, stove oil, tar oil, Carolina oil of tar, argols, sludge acid, fuel oil, wood creosote and H_2SO_4 . The best combination for the treatment of slime was found to be H_2SO_4 , sludge acid kerosene, wood creosote and stove oil. The recovery by flotation treatment of round table tailings is no higher than that from direct flotation of slime and the retention of the round tables would, therefore, not be economical. In direct treatment the resulting tailings assayed less than 0.30% Cu with a concentrate carrying not more than 40% insol. The tests proved, furthermore, that the best circuit density for the slime pulp is 12% solids and its optimum temp. 21° and that the presence of acid is essential. The peripheral speed of the agitators should not exceed 1300 ft. per min. Results of tests on mill tailing ground through 60 mesh showed again that sludge acid kerosene and H_2SO_4 made the best combination. Tailings assayed not more than 0.10 Cu and the concentrate carried less than 30% insol. The temp. of the pulp should be 21° and while the presence of acid is beneficial it is not so important as in slime treatment. Compared with the Minerals Separation machine the Callow pneumatic is more sensitive and needs more attention but on the other hand requires fewer repairs. With mill tailing ground through 60 mesh the use of the agitator is unnecessary if the oil is added before the grinding and power costs are therefore lower. H. L. OLIN.

Recovery of white metal from drosses. A. BREGMAN. *Metal Ind.* 14, 103-6 (1916).—The different kinds of drosses are classified according to compn. as follows: (1) Solder—Pb and Sn, (2) tin, (3) lead, (4) hard—Pb, Sb and Sn, (5) Babbitt—Pb, Sb, Sn and Cu. In smelting it is essential not to mix the different kinds. The furnace employed is of the simplest reverberatory type, either coal, gas or oil fired. Detailed directions are given for sweating and smelting, with methods of overcoming difficulties which inhere in the process. Too thick a slag is caused by too much SiO_2 in the dross. This is remedied by the addition of $NaHSO_4$, or of scrap iron. If too much oxide is left in the furnace after the tap, coal, preferably anthracite, should be added. Drosses containing a low % of metal, high % of SiO_2 or residues from sweating rough pigs are found to be refractory. L. W. RIGGS.

Mineral production of the United States in 1914. A summary. H. D. McCASKEY. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. I, 64 pp. (separate A, published February 10, 1916). E. J. C.

The production of platinum and allied metals in 1914. JAMES M. HILL. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. I, 333-52 (separate, published Oct. 18, 1915). E. J. C.

A development of practical substitutes for platinum and its alloys with special reference to alloys of tungsten and molybdenum. FRANK A. FAHRENWALD. Univ. Michigan. *Bull. Am. Inst. Mining Eng.* 1916, 103-49.—A substitute for Pt should melt well above 1200°, should not be easily attacked by chemicals nor by O, should be strong and fairly pliable, should have a low coeff. of expansion, should alloy well with Au, Ag and similar metals and their solders, and should be cheaper than Pt. A consideration of the periodic law indicates that a Pt substitute can hardly be expected except with alloys of the elements Cr, Mn, Fe, Co, Ni, Cu, Ag, Pd, Au, Mo, and W. Each of these 11 elements was combined in varying proportions with each of the other 10, giving 55 series of binary alloys which were examd. with regard to their suitability as Pt substitutes. Behavior under the hammer, or when drawn through draw plates, and treatment with acids and alkalies was sufficient to show whether any particular specimen should be discarded at once. Expts. with the metals having m. p. within the limits of ordinary fusion methods showed that metals or alloys outside of the precious metal groups are unsuitable as substitutes for Pt. Au and Ag alloys with Pd are excellent substitutes for Pt in its softer forms and, although not so resistant chemically as Pt, will fulfil all requirements when the conditions are not too rigid. Except with regard to ease of oxidation and difficulty with soldering, pure, ductile W and, to a lesser degree, Mo meet all the specifications of a practical substitute for Pt and its alloys. The defects can be overcome by coating with a precious metal or alloy, the resulting metal being in some respects superior to Pt and its alloys. This material has met with commercial demand and has replaced already some of the best Pt-Ir alloys. The theoretical and practical considerations involved in the manuf. of wrought W and Mo are discussed at length. Wrought W and Mo were produced on a lab. scale but the attempted production of alloys of W with Au and with Pd was not successful; on the other hand the alloys of the W-Mo series were produced in wrought form. These operations were governed by metallographic control and their success indicates the possibility of a similar method in the treatment of such metals as Ir, Ta, Rh, Os, etc., in combination with one another or with Mo in the hope of producing alloys superior to any now available.

W. T. H.

The relation of ductility to elongation. H. FRIEDMANN. *Machinery* 22, 508-9 (1916).—No strict proportional relationship exists between ductility and elongation and deductions from local distribution of lengthening give better results. A high value of local elongation corresponds to a reduction of area at the point of fracture and the % reduction bears a close relation to ductility. Diagrams of local lengthening are given. The more marked the elevation near the point of fracture, the more ductile the metal, and the straighter and more uniform the line the more brittle the metal. The av. elongation measured by mean ordinate of the diagram is not as important as the general character of the curve. Ductility is judged approx. from the outline of the curve for the broken test-bar. The outline is of less distinct character than the elongation diagram, for the former is proportional to the square root, and the latter to the full value of the area.

W. H. BOYNTON.

The preparation, fusibility and some other properties of silicates of the system $2\text{FeO} \cdot \text{SiO}_2 + 2\text{CaO} \cdot \text{SiO}_2$. B. SĖLIVANOV. *Rev. Soc. Russe Metal.* [2] 1915, 328; *Rev. Metal.* 12, 309-18.—The method of prepn. consisted in heating weighed quantities of FeO, SiO_2 and CaO in a Pt boat to a certain temp. for a given time. The fusion mixt. was protected from oxidation by heating it in an atm. of purified N. The mass was allowed to cool, withdrawn from the furnace and in case fusion had not occurred, heated again for the same time at a higher temp. As a result of heating, the FeO forms Fe and Fe_3O_4 to some extent. Expts. show that in monosilicate slags of the type $(\text{FeO} \cdot \text{CaO})\text{SiO}_2$ the oxide Fe_3O_4 acts as an acid. FeO and Fe_3O_4 furthermore easily unite to form the magnetic oxide Fe_3O_4 . The magnetic permeability of the system slowly increases with the temp. but decreases rapidly after attaining a max. In the slag obtained no complete sepn. of the salts of Ca and Fe from the silica could be made, even by boiling with *aqua regia* followed by evapn. The slags dissolved completely only in HF. The amt. of Fe that passed into soln. on boiling with dil. H_2SO_4 (10%) was detd. by titration with KMnO_4 . In the case of silicates containing 60% $2\text{CaO} \cdot \text{SiO}_2$ the Fe dissolved entirely. Slags containing less than 60% showed a lower solubility of Fe in the acid. Detns. of the density of a number of slags were made. The density diminishes about 0.03 for each increase of 1% in SiO_2 content. Expts. were made to show the reducing action of H on the slag. For this purpose, the latter was placed in a Pt boat and subjected to the action of H, the temp. being controlled by means of a thermoelement. The results indicated a lower temp. of reduction than found by Kohlmeier for the ferrates $\text{CaO} \cdot \text{Fe}_3\text{O}_4$.

L. T. FAIRHALL.

Magnetic studies of mechanical deformation in certain ferromagnetic metals and alloys. H. HANEMANN AND PAUL D. MERICA. *Bull. Am. Inst. Mining Eng.* 1915, 2371-85.—To determine whether relations exist between the physical and magnetic constant of soft Fe simultaneous magnetic and mechanical measurements were made in a tensile-testing machine. It was found that the permeability of Fe is independent of the previous elastic history of the metal provided the alternations or cycles of stress have been within the elastic limit and the number of alternations has been small. A close and nearly linear relation exists between the elastic limit of soft Fe and the values of the stress at which the permeability maxima occur as the material is elongated. The magnetic method indicates the maximum stress to which annealed Fe has been subjected provided the stress has been above the elastic limit and thus is applicable to the study of the previous mechanical history of such Fe. The permeability of annealed Fe is not affected by stress applications under the elastic limit. The effect of initial stresses upon the form of the induction-stress curves was detd. in the case of the material as received, before annealing and after quenching in water.

W. T. HALL.

Recrystallization of cold-worked alpha brass on annealing. C. H. MATHEWSON AND ARTHUR PHILLIPS. Yale Univ. *Bull. Am. Inst. Mining Eng.* 1916, 1-50.—

Strips of brass (70 Cu, 30 Zn) were cut from sheets of metal which had been reduced by cold rolling of thoroughly annealed metal and these strips were subjected to annealing expts. in order to det. (1) the general direction and magnitude of changes accomplished by heating below an effective annealing temp., (2) the time required to produce a measurable degree of softening at the different temps., (3) the microscopic aspects of strain hardening and recrystn., (4) the relations between temp. and time of annealing, degree of deformation and structural alteration in alpha brass and (5) to compare the ordinary physical properties and size of grain considered as functions of the annealing temp. for a fixed annealing period. To produce a drop of 3 points in scleroscope hardness with test pieces which had been reduced 40% by cold rolling, 294 hrs. were required at 225°, 189 hrs. at 240°, 46 hrs. at 255°, 5.25 hrs. at 275°, 2.5 hrs. at 300° and only 18 min. at 325°. After a reduction of 2% by rolling, annealing does not produce sufficient change of structure to be noticeable under the microscope. After a reduction of 4% or more, annealing produces a noticeable recrystn. and refinement of the grain. As the degree of reduction increases, the microscope reveals the structural change at successively lower annealing temps. until with 40% reduction, annealing for 30 min. at 275-300° gives a distinct visible change under 1000 diameters magnification. Assuming that a drop in hardness is due to recrystn., the expts. show that with reductions of 50, 25, 15 and 2% there is a comparatively limited range of temp. where the recrystn. process is active but when the reduction was 12, 8 and 4%, recrystn. took place throughout a wide range of temp. Probably the smallest reduction serves to develop a few widely sep'd. inner surfaces resolving the original grain into comparatively few fragmental units which break down, for the most part, only at an annealing temp. not far below the effective temp. for the grain of normal size. Medium reductions (4-12%) develop many inner surfaces of varying sizes, the smaller of which are affected by annealing at a relatively low temp. and the larger ones only at a high temp. Heavy reductions (more than 12%) develop a great many inner surfaces of uniformly small size which break down quickly at a relatively low annealing temp. The comparison of the physical properties and the number of grains per unit area of section showed that the size of the grain is by no means the only factor that affects the physical properties. The curve representing hardness and tensile strength bore no close relation to the number of grains but, on the other hand, the curve representing reduction of area in the tensile test showed a max. in the temp. region corresponding to a rapid change in the number of grains. As regards method of testing hardness, the Brinell ball test and the Ludwig cone test are no more sensitive than the scleroscope test and their only advantage lies in the fact that the respective results are more easily recalcd. in the terms of other properties.

W. T. HALL.

A transformation of copper. H. HERRENSCHMIDT. *Bull. soc. ind. Rouen* 43, 141(1915).—A yellow metal is produced by a thermal reduction using CuO , V_2O_5 , Al powder and Cu bars.

MILES R. MOFFATT.

The hardening of copper. L. GUILLET. *Rev. metal.* 12, 819-25(1915).—G. points out the fact that the hardness of Cu as defined by the Brinell hardness test is inexact. The size of the steel sphere and the pressure employed are factors which affect the hardness value considerably. When the hardness of the Cu is relatively low, the value as defined by this test attains a relatively high value. Of 2 samples of Cu that have the same hardness number, one is safe in deducing that they are in the same state of hardness only when this value is less than 100. The microstructure of the metal is a more valuable index of hardness.

L. T. FAIRHALL.

Discussion of certain phenomena in the sprouting of silver. W. STAHL. *Metall u. Erz* 12, 501-4(1915).—Ag pptd. by Fe from sulfate soln. frequently sprouts after melting. This has been ascribed to SO_2 from decompn. of basic sulfates. It has been

shown that Ag melted in an atm. of SO_2 will not sprout. The reaction in this case is probably $4\text{Ag} + 2\text{SO}_2 \rightleftharpoons \text{Ag}_2\text{SO}_4 + \text{Ag}_2\text{S}$. The 2 compds. formed fuse together into a liquid slag leaving the surface of the metal bright. In the presence of O the reaction is probably $4\text{Ag} + 2\text{SO}_2 + 4\text{O} \rightleftharpoons 2\text{Ag}_2\text{SO}_4$. The Ag_2SO_4 easily melts and seps. from the metal. It seems, therefore, that SO_2 cannot be the cause of the sprouting. At the high temps. obtained in refining Ag the following reaction may take place: $\text{Ag}_2\text{SO}_4 = 2\text{Ag} + \text{SO}_2 + 2\text{O}$. The O becomes absorbed in the metal either physically or chemically and is released when the metal solidifies, producing the sprouting.

C. R. H.

Tempering in hot water. E. HITZEL. *Rev. metal.* 12, 584-6(1915).—Credit has been given to Langley and Metcalf for discovering in 1892 the effects of tempering in hot water. It is pointed out that H. Caron (in 1872-3) made valuable expts. along the same lines.

D. B.

Metallography of steel for United States naval ordnance. HAROLD E. COOK. *Bull. Am. Inst. Mining Eng.* 1916, 375-400.—The paper states the inspection requirements of the Bureau of Ordnance, the specifications governing the inspection, and the physical and chem. properties of the steel used in the construction of ordnance for the navy. It is suggested that the word *metallography* should signify not only the macroscopic and microscopic examn., but also the study of the relation of the internal structure of metals and alloys to their compn. and to their physical and other properties.

W. T. H.

"Ghost lines" in large steel forgings. J. O. ARNOLD. *Engineering* 100, 542-4; *Iron Coal Trades Rev.* 91, 660(1915).—In big ingots there is usually more or less segregation of the mobile elements, C, S and P, to a series of centers. Photomicrographs are shown which exhibit nodular segregation areas of (1) an isomorphous mixture of $x\text{Fe}_3\text{C}$ - $y\text{Mn}_3\text{C}$; (2) dissolved Fe_3P ; (3) irregular globules of MnS. In a forging the elongated segregation is in turning operations jumped by the tool, leaving in faint relief a white line called the "ghost." Contrary to general belief, the ghosts freeze first at many degrees above the f. p. of the main mass.

H. L. OLIN.

Determination of gases in steel. P. GORRENS AND J. PAQUET. *Iron Age* 97, 720-1(1916); see C. A. 9, 1741.

E. J. C.

The gases contained in liquid steels. L. BARADUC-MULLER. *Rev. metal.* 12, 804-8(1915).—Ingots of steel were melted and the gases contained in the liquid steel pumped off and analyzed. The steel has submitted to metallographic examn. and chem. analysis before and after removing the contained gases. It was also submitted to mechanical tests. The expts. outlined are of a preliminary nature. In one case the quantity of gas pumped out of 550 kg. of liquid steel amounted to 54.2% by vol. Of this hydrogen is the greatest constituent. The mechanical properties of the steel appear to be improved by the removal of dissolved gas. The expts. carried out serve as a preliminary investigation pending the installation of app. for treating ingots of steel of 1200 kg. under greater pressures.

L. T. FAIRHALL.

The preparation of pure iron and iron carbon alloys. J. R. CAIN, E. SCHRAMM AND H. E. CLEAVES. *J. Ind. Eng. Chem.* 8, 217-24(1916); Bur. Standards, *Sci. Paper* No. 266; *Bull. Bur. Standards* 13, 1-26(1916).—Some of the previous work on the Fe-C diagram is unsatisfactory because of the impurity of the materials. To form the basis of a redetn. of the diagram at the Bureau of Standards, a series of Fe-C alloys, with not over 0.04% of impurities has been prepared by melting electrolytic Fe with sugar carbon in magnesia crucibles. The electrolytic Fe was prepd. from ingot iron anodes in a chloride bath with or without the use of porous cups. The Fe was melted with C in a vacuum furnace, using crucibles of especially pure MgO .

E. S.

The magnetic properties of some iron alloys melted in *vacuo*. T. D. YEWSEN. *Proc. Am. Inst. Elec. Eng.* 34, 2455-95(1915); cf. C. A. 9, 906, 1892, 2037.—Y. deals with Fe-B and Fe-Si alloys which have been made from pure materials, using doubly refined electrolytic Fe as a base, and fused *in vacuo*. B was found to have a slightly beneficial effect if used in small amts., but if any measurable amt. combined with the Fe it produced pronounced detrimental results upon the magnetic properties. Weiss' alloy Fe₃Co was also prepd. and it was found that it had a satn. value 13% higher than that of pure Fe, or 3% higher than hitherto found. It is brittle but fairly strong. In the Si series the 2 best alloys for magnetic purposes were obtained with about 0.15% and 3.4% Si after annealing at 1100°. The values for max. permeability for both of these are above 50,000 and the hysteresis loss for B_{max.} = 10,000 and B_{max.} = 15,000 are about 300 and 1000 ergs per cu. cm. per cycle, respectively. This hysteresis loss is 1/3 and 1/5 of the corresponding loss for commercial Si steel. The mechanical properties were also carefully detd. and curves of results given. A so-called "critical point" of non-forgeability was found at 2.5-2.6% Si. The upper limit is 7-8% Si. The sp. elec. resistance increases about 13 microhms for the first % Si, and 11 microhms for each additional % Si added. A large number of photomicrographs are given.

W. E. RUDER.

The action of boiling acetic, propionic and butyric acids on aluminium, with a note on the action of formic and some higher acids. R. SELIGMAN AND P. WILLIAMS. *J. Soc. Chem. Ind.* 35, 88-93(1916).—The main factor in the corrosion of Al, according to the expts. carried out by S. and W., is not the presence or absence of air. The question of acid concn. is all important, however. In the case of acetic acid, the rate of dissolution falls as the acid concn. increases, so that 99% acid has only 1/10 the action that a 90% acid has. The removal of the last 0.05% of water, however, raises the rate of dissolution 100-fold. The acetate formed by the action of the dehydrated acid on Al is a cryst. substance differing from the acetate prepd. from less concd. acids. Boiling butyric acid of 99% strength has practically no effect on Al. A more concd. acid, however, attacks the metal in a manner similar in all respects to the action of acetic acid. Similar effects were observed in the case of propionic acid. Boiling formic acid of 77% strength attacks Al very rapidly. Mixts. of palmitic, stearic and oleic acids do not attack the metal below 270°, but the metal is invariably attacked when the temp. rises above 300°. Two views are given to account for the action of these acids (1) that with acids of low concn. a gelatinous film of basic acetate coats the metal, whereas with acids of high concn. a cryst. coating is formed which does not protect the metal, and (2) with acids of low concn. a film of oxide protects the metal, whereas in the absence of H₂O no film is produced, leaving the metal susceptible to attack.

L. T. FAIRHALL.

The action of certain chlorinated hydrocarbons on some metals in the presence of moisture. S. G. SASTRY. *J. Soc. Chem. Ind.* 35, 94-5(1916).—Thin strips of metal (mild steel, wrought iron, Ni, Cu, Al, Pb) were heated with the chlorinated hydrocarbons (CCl₄, C₂H₂Cl₄, C₂HCl₃, C₂H₂Cl₃, C₂HCl₂) under a reflux condenser for 10 hrs. and the influence of the solvent found by weighing the strips before and after heating. The losses observed were greatest in the case of CCl₄, C₂H₂Cl₄ and C₂HCl₃. With C₂H₂Cl₂ no action whatsoever was observed and in the case of C₂HCl₂ the action was extremely slight.

C. G. F.

The composition of some German shells. J. E. STEAD. *Iron Age* 97, 536-7(1916).—Shells in large numbers were thrown on the northeast coast of England on Dec. 16, 1914. Fragments of these shells have been collected and analysed. The

armor-piercing shells were easily detected by the presence of Ni and Cr. Such shell material contained about 91.86% Fe, 0.50-0.84% C, 0.38% Mn, 0.40% Si, 0.03% S, 0.03% P, 3.1% Ni and 3.35% Cr. Most of the fragments were small but the fractures indicated material of very high tenacity. The analysis of these shells corresponds with the analyses of similar material made in other countries. The analyses of the high explosive shells, however, showed a very wide range in chem. compn. The max. and min. amts. of each element were: 0.39-1.12% C, 0.38-1.40% Mn, 0.08-0.60% Si, 0.027-0.083% S, 0.028-0.105% P. Such material is of less uniform quality than that corresponding to English specifications. The steel is of relatively high tenacity and much more liable to break by shock than English steel. The presence of considerable N in one of the toughest and best fragments leads to the conclusion that N is not harmful and that basic Bessemer steel is suitable provided sufficient Si and Mn are present to ensure soundness. If steels with 0.07 and 0.1% P did not burst in the gun, it seems probable that great freedom from P is not as important as has been thought.

W. T. H.

The chemistry of the iron war coins. RICHARD LUCAS. *Gera. Z. physik. chem. Unterricht* 29, 29-30 (1916).—The coins are Siemens-Martin steel galvanized by heating in closed vessels with Zn dust to 260-315°.

J. H. MOORE.

Heat treatment of chains. G. S. TAYLOR. *Iron Age* 97, 713 (1916). The metal of a chain deteriorates with use but the tenacity can be maintained by periodic annealing so that accidents are avoidable. The various annealing methods employed in English works are described.

W. T. H.

Nick and break test in rail inspection. ROBERT W. HUNT AND C. W. GEMMET, JR. *Iron Age* 97, 722-6 (1916).—Evidence is cited to show that the nick and break test is reliable as a protection against the acceptance of rails having pipes, laps or any interior mechanical defects. The test made on every ingot is a protection to the buyer and is accomplished with a minimum expense on the part of the seller.

W. T. H.

The corrosion of high chromium steels. ROBERT HADFIELD. *Iron Age* 97, 202-3 (1916).—The special alloy known as stainless steel contains about 0.3% C, 0.01% Si, 0.12% Mn, 12.7% Cr, 0.45% Co and 86.6% Fe. This steel does not show satisfactory resistance to corrosion in the 10% H₂SO₄ test. It is doubtful, therefore, whether high Cr steels are suitable for resisting corrosion in such media as sea water. On the other hand, an alloy with 9.18% Cr and 0.71% C resists corrosion very well.

W. T. H.

Autogenous welding of steel tubing. ANON. *Iron Age* 97, 135 8 (1916). A new welding process is described in which continuous oxy-acetylene welding machines are used.

W. T. H.

The alloys of manganese and gold. N. PARRAVANO with U. PRENAT. Univ. Padova and Rome. *Gazz. chim. Ital.* 45, 1, 293 303 (1915). An earlier paper (C. A. 9, 1454) on Zn-Mn furnished a new example of the similarity of behavior of various metals that exists between Mn and Fe, Co and Ni. The system Zn-Mn shows the compds. MnZn₂ and MnZn₃; with Zn-Fe there is FeZn₂ and FeZn₃. In order to extend the knowledge of these relationships, the alloys of Mn-Au were studied. Tammann (C. A. 1, 1953, summarized the work on the behavior of the Cu, Ag, Au group on Mn, Co and Ni and found a marked regularity in the variations of the one series with the other. Cu forms a continuous series of mixed crystals with Mn, with Fe the series shows a break between 2.5 and 4% Cu, with Co the break is from 10 to 14% Cu; with Ni there is complete miscibility in the whole alloy but the capacity of Mn to form mixed crystals is less than in Fe. Ag behaves like Cu with Mn, Fe, Co and Ni. Au shows complete miscibility with Fe, Co and Ni and interpenetrates and miscibility in

Au-Fe between 20 and 82% Fe, in **Au-Co** between 6 and 96.5% CO and in **Au-Ni** between 8 and 80% Ni. Through analogy with Ag and Cu one could expect complete liquid and solid miscibility in **Au-Mn**, more extended than in **Au-Fe**. It was found that Mn dissolves in the solid state in Au up to 10.5% and Au in Mn up to 25%. Of these solubilities the one is less and the other greater than the values for **Au-Fe**. The fusion diagram is more complicated than any of the above, for it shows a definite compd. **AuMn**, that can dissolve Au or Mn in the solid state; it shows a liquid break between 50 and 57.5% of Mn and it also shows complex transformations of an indefinite nature in the solid state. This behavior removes Mn and Au from any close analogies with the above elements. The expts. were done in the usual manner. The fusions were made in Berlin porcelain crucibles up to 45% Mn and in magnesia crucibles above 45% Mn.

The exptl. detns. between 100 and 55% Au are not difficult; at less concns. of Au the detns. of crit. points are involved with marked supercoolings. For alloys between 100 and 60% Au the points on the f. p. curve were detd. 3 times in each alloy, while between 57.5 and 0% Au the detns. were made at least 6 times on 2 specimens of each alloy. The diagram of state was thus detd. with much difficulty. At 990° there is an arrest for the solid break between 10.5 and 14% Mn. At 1140° and at 1080° there are also true arrests, the duration of which could not be accurately detd. On adding Mn the m. p. of Au drops to 990° at 10.5% and seps. mixed crystals which may be interpreted as follows: (1) There is a m. p. curve of mixed crystals with a minimum or (2) the horizontal eutectic at 990° extends a little to one side of the minimum. Similar relations have been found for **Pd-Pb** between **Pd₃Pb** and **Pd** (*Z. anorg. Chem.* 52, 355 (1907)) and in **Au-Cd** between **AuCd** and **Au** (*Saldau, C. A.* 9, 779). This point was discussed at length and left undecided. On increasing the Mn content beyond 10% the m. p. rises and reaches a max. at 1225° at 21.8% Mn. Between 10 and 14% Mn there is a primary and a secondary solidification at 990°, resulting from 2 constituents, a primary and a secondary eutectic. On increasing the Mn content again the m. p. drops regularly to 1080° at 46% Mn. Between 21.8 and 30% the alloys solidify in a single interval of temp. and are homogeneous; those solidifying between 30 and 46 solidify in 2 layers and have a heterogeneous structure, a primary constituent and a eutectic. The mixed crystals that sep. at about 1080° are about 30% Mn. The max. at 21.8% Mn corresponds to the compd. **AuMn**. From 46% Mn on the m. p. rises irregularly to that of Mn; between 50 and 57.5% Mn the curve is broken by a horizontal line due to partial liquid miscibility. The mixts. in this region are sepd. in 2 liquid layers in the liquid state. It was not possible to det. the cooling curves accurately above 75% Mn. On roasting the 80 and 90% Mn alloys they assume a homogeneous structure of coarse crystals after a few hrs. at 1000–50°. The 70% Mn alloy gives on first cooling a primary constituent and a eutectic; after roasting as above a small amt. of the eutectic remained. This alloy is thus near the limit of solid miscibility. The 75% Mn alloy treated thus became homogeneous and so the concn. of a satd. soln. of Au in Mn was fixed at 25% Au. The alloys from 30 to 90% Mn undergo a transformation ranging between 700° and 550°, which is accompanied by strong supercooling and weak thermal effects, but which could not be precisely detd. This transformation is accompanied by a considerable increase of vol. such that the crucible was frequently burst. Alloys between 45 and 70% Mn roasted 20 hrs. at 500° showed that the coarse crystals are reduced to minute cryst. aggregates but no conclusions as to the nature of the reaction were drawn. The alloys between 14 and 30%

Mn are composed of a phase that may vary in compn. in a continuous manner between these limits and that is clearly sepd. from the solids nearly at the middle of the 2 eutectic intervals. The m. p. curve with a max. at 21.8% Mn and the homogeneous structure have led to the admission that a chem. compd., AuMn, is formed. Kurnakov (C. A. 4, 435; 8, 1080, 2089) showed that a phase of variable compn. in which a definite compd. may be present ought to have at an invariable compn. a discontinuity in the curve representing the property. If this discontinuity is lacking the max. on the m. p. curve ought to be interpreted as an irrational max. that is characteristic of pairs of solid solns. and the solid phase ought to be considered a compd. of variable compn. In accordance with this idea the significance of the point at 21.8% Mn was studied by detg. the hardness diagram for alloys from 0 to 35% Mn in the app. of Meneghini (C. A. 9, 1453). The results show that with increasing Mn the hardness of Au gradually but not linearly increases up to about 10% Mn, i. e., the limit of miscibility in the solid state. From 10 to 14% Mn it increases linearly in accordance with the heterogeneous nature of the alloy for this interval. From 14 to 35% it at first increases to a max. at 15% and then diminishes to a minimum at 21.8% Mn. It then rises again and finally varies at a nonlinear arrest near the upper limits of satn. of Mn. The minimum on the hardness curve corresponds exactly with the max. on the m. p. curve and thus contains the compd. AuMn.

E. J. WITZEMANN.

Blistering of gold alloys. H. D. COLEMAN. *Metal Ind.* 14, 118(1916).—When high grade Au, 999 + fine, and pure electrolytic Cu are used and the melt is kept covered with charcoal, there should be no blister troubles if the metal is not poured too hot. The annealing temp. should usually be about 650°. High grade ingots which are void of ring and lack malleability are often helped by heating with 0.025% of Cu-Cl₂ + 2H₂O.

Influence of frequency of alternating or infrequently reversed current on electrolytic corrosion (McCOLLUM) 4. Earth resistance and its relation to electrolysis of underground structures (McCOLLUM) 4.

Soldering. J. LAVINE. *Brit.*, 22,356, Nov. 11, 1914. In gold soldering, particularly Ni or Ni alloys, Fe or Fe alloys, or for dental purposes, the gold solder is formed during the process of soldering. The parts to be joined are first united by Ag solder, and Au is then applied to the joint and heated to m. p. so that it may alloy with the Ag alloy.

Non-oxidizing heating of iron. W. MÖLLHOFF. *Aust.*, 70,920, Jan. 10, 1916. Continuous heating of Fe and metal articles in a gas-tight, closed, undivided chamber filled during the heating with reducing (combustible) gases. Before, as well as during the charging of the furnace, incombustible indifferent gases are introduced into the heating chamber, for the purpose of forcing out the combustible gases, whereupon, after closing the furnace, combustible gases are introduced, with expulsion of the indifferent gases.

Crucible melting furnace. V. MASEK. Aust., 70,741, Dec. 27, 1915. A pre-heating crucible is disposed over the melting crucible, with a space between the two crucibles to allow passage of the heating gases.

Open-hearth furnaces. J. WARD and A. P. TOWNSEND. Brit., 22,789, Nov. 20, 1914. The furnace is heated by the combustion of liquid fuel in two stages, the first stage of partial combustion with regeneratively heated air takes place in the gas-producing chamber, and the combustion is completed in the melting chamber by further supplies of heated air.

Concentrating ores. MINERALS SEPARATION and DE BAVAY'S PROCESSES AUSTRALIA PROPRIETARY, LTD. Brit., 22,145, Nov. 6, 1914. Mixed sulfides are sepd. by subjecting ores, concentrates, tailings, slimes, etc., to a froth-flotation process in H_2O to which a permanganate of an alkali metal has been added without a frothing agent, whereby a concentrate relatively rich in certain sulfides is obtained, leaving a residue relatively rich in other sulfides which may be recovered by known processes. Cf. C. A. 9, 2220.

Tin, terne, and like plates. D. R. JAMES. Brit., 22,587, Nov. 16, 1914. Sn, terne, and other plates coated with metal on one side only are produced by passing the plates in pairs, back to back, through the coating app. Cf. C. A. 9, 2638.

Decorating aluminium surfaces. F. SCHÖNBACH and M. TISCHER. Aust., 70,914, Jan. 10, 1916. See Ger., 280,940, C. A. 9, 1540.

Refining nickel. L. P. BURROWS. Can., 165,916, Nov. 9, 1915. Desulfurizing, reducing and refining Ni by applying the gas or gases derived from H_2O , which are produced by suddenly expanding steam, separating the steam without condensation from any H_2O suspension, heating the gaseous product to a high temp. and then subjecting the Ni ore to the action of the resultant gaseous product in a chamber from which atmospheric O is excluded.

Reduction of precious metal ores. W. H. JAMES. Can., 166,137, Nov. 23, 1915. Process of treating refractory precious metal ore, by electrolyzing a soln. of a salt of a mineral acid, withdrawing separately from the electrolytic circuit the portion of the soln. in the vicinity of one of the electrodes, treating the ore therewith until the refractory constituents are dissolved and removing the soln. and with it the refractory constituents, whereby the ore is left amenable to the ordinary cyanide process for the extn. of the precious metal.

Biochemical synthesis of glucosides of alcohols. III. Monoglucosides of polyvalent alcohols. E. BOURQUELOT. *Ann. chim.* 4, 310-79(1915); cf. C. A. 8, 938, 2675, 3180, 3438; 9, 1309, 2521, 2639.—Collective article. LOUIS E. WISE.

Characterization of chloroketones. E. E. BLAISE. *Bull. soc. chim.* 17, 425-8 (1915).—The ketones previously described (cf. C. A. 8, 3777; 9, 786) yielded characteristic semicarbazones. Unsym. Cl ketones of the type $CHCl_3COR$ gave normal or disemicarbazones depending on the amt. of $H_2NCONHNH_2$ used. Those of the type $RCCL_3COR'$ yielded disemicarbazones. In general the latter could be distinguished from the normal compds. by their marked insoly. in org. solvents (other than AcOH and

LOUIS E. WISE.

(excluding HCO_2H).

LOUIS E. WISE.

Alkaloids of the Calabar bean. IV. Partial synthesis of eserine and geneserine. MAX POLONOVSKI AND CHARLES NITZBERG. *Bull. soc. chim.* 19, 27-37(1916); cf. *C. A.* 9, 3222.—Eseroline (A) and geneseroline (B) were readily obtained by the hydrolysis of eserine (C) and geneserine (D), resp., in the presence of 50% H_2SO_4 . By heating 0.5 g. of (A) in 10 cc. benzine with 0.22 g. MeCNO in 10 cc. benzine in a sealed tube at 100° for 4 hrs., P. and N. obtained an isomer of (C), *isoeserine* (E), $C_{11}H_{17}O_4N$, cryst., m. 195-6°; $[\alpha]_D$ in 95% alc. -236°, neutral, sol. in aq. NaOH, forming a *picrate* m. 170°, but no methiodide, and yielding $BaCO_3$ and $MeNH_2$ when treated with $Ba(OH)_2$ (but much more slowly than in the case of (C)). (E) appears to be a substituted urea deriv. of (A), with a $-C_6H_4OH$ group. Attempted esterification of (E) by means of $MeC_4H_9SO_3Et$ in the presence of EtONa led to the formation of an oil (ester?) which was not purified. When a mixt. of 0.5 g. (A) in 20 cc. anhydrous Et_2O and 1.5 g. of 10% MeCNO in benzine was allowed to stand at room temp., an addition product, *eseroline methyl isocyanate* (F), $[C_{11}H_{17}(OH)N]NMeCNO$, powder, softens 102°, m. 110-15°, was obtained. (F) was converted into (E) on heating at 110° or when heated in benzine. (C), m. 106°, was synthesized by treating (A) in anhydrous Et_2O with 0.0005 g. Na and subsequently with 15 g. of 10% MeCNO in benzine. (C) was shown to be identical with natural eserine; its salicylate, m. 181°; benzoate, m. 116°.

(B), 0.5 g. in 20 cc. anhydrous Et_2O , when treated with Na and subsequently with 0.15 g. MeCNO , yielded (D), m. $126-7^\circ$, identical with the natural product. (B), unlike (A), yields no products analogous to (E) or (F). When (A) in benzene was heated with 2 mols. MeCNO in a sealed tube in the absence of Na, a mixt. of (E), (C) and an uncrystallizable oil, probably a urea urethan, $\text{C}_{13}\text{H}_{18}\text{N}(\text{OCONHMe})\text{CONHMe}$, was obtained. The latter was probably identical with an oil, a by-product formed in the synthesis of (E), and could not be obtained under other exptl. conditions which P. and N. have described in detail.

LOUIS E. WISSE.

True homologs of glycerol. Heptanetriol. J. L. HAMONET. *Compt. rend.* 162, 225-6(1916).—Up to the present no true homologs of glycerol (type formula $[\text{HOCH}_2(\text{CH}_2)_n]\text{CHOH}$, have been described. Attempts to prepare 1,3,5-pentanetriol were unsuccessful. $\text{MeO}(\text{CH}_2)_3\text{MgI}$ when acted upon by HCO_2Et and the product hydrolyzed by H_2O gave rise to 1,7-dimethoxy-4-heptanol (A), $[\text{MeO}(\text{CH}_2)_3]\text{CHOH}$, b. $246-8^\circ$, d_{18} 0.969, which could be readily converted into 1,4,7-heptanetriol, $[\text{HOCH}_2(\text{CH}_2)_3]\text{CHOH}$ (B), bitter, viscous liquid, b. $230-2^\circ$, d_{18} 1.075, by treatment with HI. A less satisfactory method of converting (A) into (B) involved the use of HBr, which first yielded $[\text{CH}_2\text{Br}(\text{CH}_2)_3]\text{CHOH}$ (C) or $[\text{CH}_2\text{Br}(\text{CH}_2)_3]\text{CHBr}$ (D) (depending on the temp. of the reaction), which in turn were transformed into the corresponding di- and triacetins. The latter yielded (B) on hydrolysis. Attempts to hydrolyze (C) or (D) by boiling with H_2O led to the formation of $\text{HOCH}_2(\text{CH}_2)_3\text{CH}_2\text{CH}_2\text{CH}_2\text{CH}_2\text{O}$

LOUIS E. WISSE.

Nitro derivatives of o-toluic acid. MAX MAYER. *Wien. J. prakt. Chem.* 92, 137-73(1915).—These derivs. have been prepd. from the corresponding nitrotoluidines by the Sandmeyer reaction with subsequent hydrolysis of the resulting nitriles. 5-Nitro-2-toluenitrile (a), from 5-nitro-2-toluidine (b), by decomp. the diazonium chloride with $\text{KCu}(\text{CN})_2$ at 70° , seps. from alc. in yellow needles, which an. $113-15^\circ$, sublime on slow heating, and can be steam distd. only with difficulty. By concd. KOH (a) is readily hydrolyzed with the formation of 5-nitro-2-toluic acid, which corresponds in all respects to the "γ-nitrotoluic acid" of Jacobsen (cf. *Ber.* 17, 162). (a) is not reduced to the corresponding NH_2 compd. by either $\text{Sn} + \text{HCl}$, $\text{NH}_3 + \text{H}_2\text{S}$, $\text{Zn} + \text{HCl}$, $\text{SnCl}_2 + \text{HCl}$ or $\text{Zn} + \text{AcOH}$ (cf. Beilstein and Kreisler, *Ann.* 144, 175), which behavior may be considered according to M. as a case of steric hindrance. The Me group of (a) cannot be oxidized to CO_2H without the simultaneous hydrolysis of the CN group; although many oxidizing agents were employed 5-nitro-o-phthalic acid ("β-nitrophthalic acid") was always formed (cf. *Ann.* 208, 229). 3-Nitro-2-toluenitrile (c), from 10 g. 3-nitro-2-toluidine (d) by diazotization in an excess of glacial AcOH with 10 cc. HCl (d. 1.2) and 5 g. pulverized NaNO_2 at 0° , with subsequent treatment with $\text{KCu}(\text{CN})_2$, at 80° , lustrous branching yellow needles from alc., m. $89-91^\circ$. The following generalities in regard to nitrotoluenitriles may be made: Those compds. in which the NO_2 is adjacent to Me have the lowest m. ps.; those in which the NO_2 is adjacent to CN possess m. ps. midway between those with these groups in the 1:3 and 1:4 positions. When Me and CN are 1:3, the products are colorless; 1:4, yellow; 1:2, either colorless or yellow; and when the Me and NO_2 are 1:3 the products are yellow; 1:4, white; 1:2, usually, but not always, colorless. No uniformity in color is observed when the relative positions of the CN and NO_2 are considered. 3-Nitro-2-toluic acid (e) is formed in 80% yield by hydrolysis of (c) with concd. aq. KOH (preferably) or dil. H_2SO_4 , needles from alc., of indefinite m. p. ($200-210^\circ$), partially subliming and partially decomp. into its anhydride; sodium salt, 2 H_2O , efflorescent monoclinic columnar prisms from H_2O ; potassium salt, needles from alc.; ammonium salt, hexagonal leaves from H_2O , which lose NH_3 on standing; silver salt, small tables

from H_2O ; *lead salt*, slender rhombic needles from H_2O ; *copper salt*, bluish green rectangular tables from alc.; *magnesium salt*, efflorescent cubical crystals containing several (?) mols. H_2O ; *barium salt*, 3 H_2O , large prisms from H_2O ; *calcium salt*, H_2O , radiating leaves; *zinc salt*, wart-like formations from H_2O ; *neutral aluminium salt*, cryst. crust from H_2O or alc. (e) is not esterified by treatment with MeOH or EtOH in the presence of HCl; with Me_2SO_4 , the *methyl ester* is obtained in small yield, needles, m. $72-5^\circ$, but with Et_2SO_4 , no Et ester is formed. Both (c) and (e) are oxidized by boiling alk. $KMnO_4$ to " α -nitrophthalic acid" (Beilstein and Kurbatow, *Ann.* 202, 217, and Miller, *Ann.* 208, 237). 3-Amino-2-toluic acid (f), from (e) by reduction with Sn and HCl, is so unstable, breaking up into CO_2 and *m*-toluidine, that it cannot be isolated; its formation in soln., however, was demonstrated by conversion into 3-hydroxy-2-toluic acid. The diazotized soln. of (f) may be converted by $KCu(CN)_2$ into *vic*-methyl-*o*-phthalic acid, while an aq. soln., evapd. *in vacuo* treated with Ac_2O + AcONa and then with $KMnO_4$, and finally hydrolyzed, gives *vic*-amino-*o*-phthalic acid. On standing 2 weeks, (e), which m. $200-210^\circ$ and is rather easily sol. in H_2O when freshly prepd., apparently passes into a structural isomer, difficultly sol. in cold H_2O and m. $180-5^\circ$ (decompn.). This 2nd form on heating reverts to the sol. form. The isomers do not differ chemically and M. suggests the following structures: $MeC_6H_4(NO_2)CO_2H$ (the sol. form) and $MeC_6H_4.CO.O.N.O.OH$. NORMAN A. SHEPARD.

Dimolecular nitriles. E. VON MEYER. Dresden. *J. prakt. Chem.* 62, 174-93 (1915); cf. C. A. 8, 3045. I. The action of dinitriles on ketones. With KURT WAGNER. (Preliminary report on work interrupted by the death of W.).—The behavior of dinitriles, $RC(:NH)CH_2CN$, towards ketones is exactly analogous to their behavior towards aldehydes (cf. Mohr, *J. prakt. Chem.* 56, 125 (1897); Klemstück, C. A. 3, 1747). One mol. of the ketone reacts with 2 mols. of the dinitrile in the presence of 1 mol. HCl in alc. at 5° , when allowed to stand for several days, forming derivs. of dihydropyridine. The behavior of AcMe, AcEt, AcPr, $AcCH_2Ph$, Et_4CO , cyclohexanone and methylcyclohexanone toward $MeC(:NH)CH_2CN$; AcMe, AcEt, AcPr, AcBu, $AcCH_2Ph$, Et_4CO , AcPh, cyclohexanone, methylcyclohexanone and $(AcH)_3$ toward $PhC(:NH)CH_2CN$; and AcMe, AcEt, AcPr, $AcCH_2Ph$, Et_4CO , cyclohexanone and methylcyclohexanone toward *p*- $MeC_6H_4C(:NH)CH_2CN$ has been investigated and the % yields of the dihydropyridines recorded, but all exptl. data are reserved for a future communication. The yields with the last dinitrile are especially good. The CN groups in the dihydropyridines formed cannot be hydrolyzed to the corresponding acids; all the dihydropyridine derivs. obtained from ketones containing Ac,

$MeCR.C(CN):CR.NH.CR:CCN$, on oxidation with CrO_3 in AcOH, lose the H of the NH and the radical R, forming 4-methylpyridine derivs. II. New dinitriles; derivatives of benzoacetodinitrile. With ELIS. SPRECKLE. The dinitriles obtained from the Cl derivs. of PhCN have been investigated in order to ascertain the effect of the Cl on the chem. behavior of the products. *o*-Chlorobenzoacetodinitrile (a), $ClC_6H_4C(:NH)CH_2CN$, from 26 g. *o*- ClC_6H_4CN and 17 g. MeCN in C_6H_6 with 9 g. Na, stout cubical crystals from 50% alc., m. $106-7^\circ$, is readily hydrolyzed on warming in 70% alc. with HCl to *o*-chlorophenyl cyanomethyl ketone (b), cubes from alc. m. 101° ; benzal derivative, $ClC_6H_4COC(:CHPh)CN$, leaflets, m. 90° . 1-Phenyl-4-*o*-chlorophenyl-2-

iminopyrazolone, $ClC_6H_4C:N.NPh.C(:NH).CH_3$, by the action of $PhNH.NH_2.AcOH$ in alc. on (a), needles of reddish tint, m. 137° . Treated with BzH in alc. and one mol. HCl, (a) gives 2,6-di-*o*-chlorophenyl-4-phenyl-3,5-dicyano-1,4-dihydropyridine,

$PhCH.C(CN):C(C_6H_4Cl).NH.C(C_6H_4Cl):C.CN$, crystals from alc., m. 260° . *p*-Chloro-

benzoacetodinitrile (c), yellow needles, m. 144°, is converted by HCl into *p*-chlorophenyl cyanomethyl ketone (d), light yellow needles, m. 127°; benzal derivative, needles, m. 125°. With PhNHNH₂.AcOH (c) gives 1-phenyl-4-*p*-chlorophenyl-2-iminopyrazolone, needles, m. 185°, and with BzH + HCl, 2,6-di-*p*-chlorophenyl-4-phenyl-3,5-dicyano-1,4-dihydropyridine, needles, m. 233°. *m*-Chlorobenzoacetodinitrile (e), stout prisms, m. 86°, gives *m*-chlorophenyl cyanomethyl ketone (f), leaves, m. 81°, on hydrolysis; benzal derivative, needles, m. 118°. (b), (d) and (f) all give PhCH:NNHPh when treated with PhNHNH₂. 1-Phenyl-4-*m*-chlorophenyl-2-iminopyrazolone, colorless crystals, m. 108°. 2,6-Di-*m*-chlorophenyl-4-phenyl-3,5-dicyano-1,4-dihydropyridine, needles, m. 248°. The yields of (a), (c) and (e) are approx. 70% of the theoretical quantity. *p*-Ethoxybenzoacetodinitrile (g), from *p*-EtOC₆H₄CN and MeCN in 94% yield, leaves, m. 136.5°. *p*-Ethoxyphenyl cyanomethyl ketone, crystals, m. 123°. 1-Phenyl-4-ethoxyphenyl-2-iminopyrazolone, prisms from alc., m. 188°. 4-Ethoxyphenyl-2-iminoisox-

azolone, EtOC₆H₄C:N.O.C(:NH).CH₃, from (g) and NH₂OH, needles, m. 127°. 2,6-Diethoxyphenyl-3,5-dicyano-4-phenyl-1,4-dihydropyridine, crystals, m. 194°. 2,6-Diethoxyphenyl-3,5-dicyano-4-methylethyl-1,4-dihydropyridine, from (g) and AcEt, slender filaments, m. 116°. *p*-Dimethylaminobenzoacetodinitrile (h), light yellow leaves, m. 210°. *p*-Dimethylaminophenyl cyanomethyl ketone, leaves, m. 166°. III. Hydrazine derivatives of acetodinitrile. With ELIS. SPRECKLES. When MeC(:NH)CH₂CN (i) is treated with N₂H₄, the corresponding pyrazolone is not formed, but three isomeric substances C₆H₁₀N₄, previously designated [A], [B], and [C] (cf. *J. prakt. Chem.* 52, 97). On reinvestigation, M. and S. were able to obtain but 2 of these products, [A] and [C]. They now consider the course of the reaction as follows: NCCH₂CMe: - NNH₂ + NH₂CMe:CHCN → NCCH₂CMe:NNHCMe:CHCN + NH₃ → (A) (I or II) → (C) (III or IV). [A], on diazotation and coupling with *m*-HOC₆H₄OH (l),

gives a reddish yellow dye, indicating the presence of free NH₂ (II). On the other hand treatment of [A] with HNO₃, in the absence of HCl, gives a red ppt., probably the isonitroso derivative, which is sol. in NaOH and m. 167° (decompn.), indicating -CH₂(I). With Ac₂O a monoacetyl derivative, needles, m. 140°, is formed and with PhNCO a phenylurea derivative, clusters of needles from alc., m. 188°, is produced. [C] may be diazotized, giving a brown dyestuff with (l), but it does not form an isonitroso deriv. The monoacetyl derivative, needles from alc., m. 106°; the phenylurea, needles from alc., m. 137°. IV. *N*-Halogen derivatives of dinitriles. With ELIS. SPRECKLES. Iodoacetodinitrile, m. 85°, is pptd. when (i) is treated with I in KI at room temp.; when warmed with HCl, it decomps. into NH₃, ICl and AcCH₂CN (cf. *J. prakt. Chem.* 52, 85). When *N*-chloroacetodinitrile is treated with PhNH₂ in dil. AcOH, a chlorophenylacetodinitrile, to which is provisionally assigned the structure MeC(:CHCN)NCiPh, is produced. This substance is to receive further investigation. V. *N*-Aryl derivatives of dinitriles. With ELIS. SPRECKLES. *N*-Phenylbenzoacetodinitrile (j), which Schumacher was unable to prep. from PhC(:NH)CH₂CN in aq. soln. (cf. *C. A.* 3, 1747), is formed when this dinitrile is treated with PhNH₂.AcOH in alc. at 120-30°, light yellow crystals from alc. + Et₂O, m. 187°. *N*-Phenyl-*p*-toluacetodinitrile, yellow crystals, m. 189°. *N*-*p*-Dimethylaminophenylacetodinitrile, light reddish leaves, m. 151°. *N*-

p-Methoxyphenylacetodinitrile (*k*), reddish needles, m. 123°. The reaction proceeds differently with *o*-NH₂C₆H₄OMe and will be further investigated. (*j*) in cold AcOH with HNO₃ gives 2 products, one, probably the *isonitroso derivative*, MeC(:NPh)C(:NOH)CN, a bright yellow ppt. sol. in NaOH, and the other, a brick-red powder, insol. in NaOH, m. 270°, which probably has the structure MeC(:NPh)C(CN):N.CH-(CN)CMe:NPh. Only one product is obtained in the action of HNO₃ on (*k*), the *isonitroso derivative*, needles, m. 155°.

NORMAN A. SHEPARD.

Trimethylgallic aldehyde and syringaic aldehyde. F. MAUTHNER WITH G. SZÖNYI. Univ. Budapest. *J. prakt. Chem.* 92, 194-201(1915).—Trimethylgallic aldehyde (*a*) undergoes a normal transformation with MeMgI, yielding, on hydrolysis of the addition product, 3,4,5-trimethoxyphenylmethylethylcarbinol (*b*), b₁₁ 179-80°, in 65% yield; a C₆H₆ soln. of (*a*) is employed, owing to the difficult soly. of (*a*) in Et₂O. With CrO₃, (*b*) gives 3,4,5-(MeO)₃C₆H₂COMe (*c*) (cf. Mauthner, *C. A.* 5, 281). 3,4,5-Trimethoxyphenylethylcarbinol (*d*), b₁₁ 184-5°, obtained under similar conditions from (*a*) and EtMgI, gives, on oxidation with K₂Cr₂O₇ + H₂SO₄ below 60°, 3,4,5-trimethoxyphenyl ethyl ketone, which was identified by conversion into its *p*-nitrophenylhydrazone, reddish brown needles from alc., m. 170-1°, by warming in 50% AcOH with *p*-NO₂-C₆H₄NHNH₂. 3',4',5',3,4,5-Hexamethoxychalcone, (MeO)₆C₆H₂COCH:CHC₆H₄(OMe)₂, from (*a*) and (*c*) in NaOH, light yellow needles, m. 128-9°. Acetoveratrol condenses in like manner with (*a*), forming 4',5',3,4,5-pentamethoxychalcone, bright yellow leaves, m. 131-2°, which give a blood-red color with concd. H₂SO₄. 3,4,5-Trimethoxynitrostyrolene, in 80% yield from (*a*) and MeNO₂ in alc. at -5° with alc. KOH, yellow leaves, m. 119-20°, which also produce a red color in concd. H₂SO₄. Syringaic aldehyde (*e*) with MeNO₂ gives 4-hydroxy-3,5-dimethoxynitrostyrolene, yellow leaves, m. 115-6°, producing a violet color with concd. H₂SO₄. 2.6 g. (*e*) intimately mixed with 2.6 g. BzNHCH₂CO₂H and 1.5 g. anhydrous AcONa and then heated for 2 hrs. at 100° with 6.5 cc. Ac₂O gives 3,5-dimethoxy-4-acetoxy- α -benzoyliminocinnamic anhydride, lemon-yellow needles, m. 212-3°, producing a red color with concd. H₂SO₄.

NORMAN A. SHEPARD.

Oxidation of phenolic substances. ADOLF JOLLES. Wien. *J. prakt. Chem.* 92, 202-7(1915).—J. has investigated the chem. nature of the products obtained when indoxyllic acid (*a*) and certain phenols are jointly oxidized, in order to det. the mechanism of the reaction between urine indican and thymol (*b*) in the presence of FeCl₃ (cf. *C. A.* 8, 722), which gives a violet product. When 30 g. (*a*), freed from resin by soln. in hot H₂O and filtration and kept in soln. by the addition of a small amt. of AcOH, is treated with 25 g. (*b*) in AcOH, the mixt. poured into FeCl₃.HCl soln. (110 g. in 300 cc. concd. acid) and finally poured into concd. Na₂CO₃, 4-cymol-2-indolindolignone (*c*) seps. as a reddish brown mass mixed with Fe(OH)₃. This is dried, freed from (*b*) by extrn. with ligroin and then extrd. from the Fe(OH)₃ with Et₂O. The residue after removal of the Et₂O is crystd. from PhNO₂ when (*c*) seps. in red pointed prisms, m. 218-20° (decompn.). (*c*) forms a violet soln. in org. solvents with HCl, the color reverting to red on washing out the acid. It dissolves in alkali, giving a yellow soln., from which it may be pptd. unaltered by acids. On hydrolysis with 10% NaOH, *o*-NH₂C₆H₄CO₂H is obtained and though *p*-thymotinic aldehyde could not be isolated in the mother liquors, J. believes it to be present and therefore assumes the "indolignoid" structure C₆H₄.CO CH:C(C₆H₇).CO for (*c*) (cf. Friedländer, *C. A.* 2, 2679). This

structure is supported by the fact that (*a*) will dye neither mordanted nor unmordanted animal or vegetable fibers, a thing hardly to be expected of an "indigoid" substance. (*c*) is obtained in purer form when (*a*) is replaced by *N*-acetindoxyl and the

reaction allowed to proceed in the cold for 5 days; *hydrochloric acid salt*, brownish black prisms. When α -naphthol is used instead of (b) and the reaction mass boiled with dil. Na_2CO_3 , the alk. soln. contains 4-naphthalene-2-indolindolignone which is pptd. by acids, while the residue contains 2-naphthalene-2-indolindigo (cf. Bezdzik and Friedländer, *C. A.* 2, 2680).

NORMAN A. SHEPARD.

The so-called benzeneazoanthranol and its methyl ether. G. CHARRIER. Univ. Torino. *Gazz. chim. ital.* 45, I, 502-16(1915); *Atti accad. sci. Torino* 50, 779-94(1915). —It is known that while the ethers of the hydroxyazo compds. were considered as *O*-ethers (i. e., derivs. of the enolic form), the corresponding hydroxyazo compds. keto-enol desmotropes were assigned the enol formulas of the true hydroxyazo compds. by some and the ketonic form of quinonehydrazone by others. The *N*-ethers obtained by the action of *asym*-alkylarylhydrazines on the quinones are considered as derived from the ketonic form while recent work seems to show that the free hydroxyazo compds. have the enolic form and may easily undergo a rearrangement to give the keto form. In such cases of isomerism in which there is an equil. (between an enolic and ketonic form) which can be displaced with great velocity from practically a zero concn. of the one to a zero concn. of the other isomer it is logical to admit that one cannot det. the constitution of the compd. by reactions such as alkylation. The enolic formula now generally assigned to the free stable hydroxyazo compds. shows that in this class of compds. the aromatic grouping is more stable than the quinonic, and in this form the enol H or metallic substituent is replaced with the alkyl to give the ether, so that the formation of an *O*-ether gives grounds for assigning the enol form to the compd. undergoing esterification, while the formation of an *N*-ether would support the presence of the hydroxyazo compd. in the keto form. If, as Meyer and Zahm (*C. A.* 7, 1873) suggest for the so-called benzeneazoanthranol, the alkylation takes place by addition and subsequent elimination of the group thus:

it seems logical to admit that by an analogous mechanism the *N*-ethers of this and other hydroxyazo compd. could be formed. The *N*-ethers are also distinguished from the *O*-ethers by their scission reactions, by being less intensely colored and by being hydrolyzed by dil. acids into the *asym*-alkylarylhydrazine and quinone, while the *O*-ethers are sapond. more or less easily to give the hydroxyazo compd. from which they were formed. The *O*-ethers are strongly basic (not so the *N*-ethers) and give with 2 mols. of a monobasic acid salts which undergo an important splitting reaction. The hydrochlorides heated give the alkyl chloride + hydroxyazo compd.; the nitrates give diazonium nitrate + nitrophenol, in which the diazo group is displaced by NO_2 . By the latter reaction it is possible to det. with much probability whether a keto-enol desmotope of this group should have the enol or keto formula. The general form of reaction for the enol is: $\text{ArN:NArOH}(\text{OR}, \text{NH}_2, \text{NR}_2) + \text{HNO}_2 - \text{H}_2\text{O} \rightarrow \text{NO}_2\text{ArOH}(\text{OR}, \text{NH}_2, \text{NR}_2) + \text{Ar}'\text{N}(\text{NO}_2):\text{N}$. The keto or quinonehydrazone has been found in some cases to give: $\text{O:Ar:NNHAr}'(\text{HNO}_2, \text{H}_2\text{O}) \rightarrow \text{O:Ar:O} + \text{Ar}'\text{NHNH}_2$. HNO_2 in Et_2O acting on the Me ether of phenylazoanthranol (a), gave anthraquinone + $\text{PhNMe.NH}_2.\text{HNO}_2$. (a), which may be obtained by the action of PhN_2Cl on the Na salt of anthranol, by the action of PhNHNH_2 on dibromo- or monobromoanthrone, was obtained by M. and Z. by methylating the supposed hydroxyazo compd. or by the

action of PhNMeNH_2 on dibromoanthrone and was shown to be a *N*-Me ether. But M. and Z., contrary to the opinion of Kaufler and S. (*C. A.* 1, 1280), considered the parent hydroxyazo compd. as an enol (I) and explain the formation of the *N*-ether by the addition reaction given above. This so-called benzeneazoanthranol (*b*) although it gives an *O*-Bz deriv. (derived from the OH form), different from that obtained from PhNBzNH_2 + dibromoanthrone (the *N*-Bz deriv. of the keto form), reacts with HNO_3 in Et_2O to give anthraquinone and $\text{PhNHNH}_2 \cdot \text{HNO}_3$, *i. e.*, products similar to those obtained from its Me ether (*N*-ether). If (*b*) were the azo deriv. (I) it would give

nitroanthranol as well as $\text{PhN}(:\text{N})\text{NO}_2$ which also arises in the above reaction by the action of HNO_3 on the $\text{PhNHNH}_2 \cdot \text{HNO}_3$ formed. The diazo scission of the nitrates is not a reaction that can escape the objections that a tautomeric change takes place, so that no absolute conclusions about the constitution can be drawn; still, the results with numerous hydroxyazo and aminoazo compds. that react as if they contain the azo group show this striking reaction without exception. The copulation of the diazonium salt with Na anthranolate gives a labile intermediate product as yellow flocks (K. and S.) that is probably the diazonium salt of anthranol and this in NaOH-EtOH gives the salt of anthraquinonephenylhydrazone (II), which reacts with Me_2SO_4 to give a *N*-ether or with BzCl a *N*-acyl deriv. which under the conditions is transformed into the *O*-acyl deriv. M. and Z. noted that the *O*-Bz deriv. is much more colored (red) than the parent supposed hydroxyazo compd. It is known that substituting H in this OH diminishes the color. This C. considers another argument for considering the parent compd. a quinonehydrazone which undergoes a tautomeric change in this reaction. It is concluded that (*b*) is *anthraquinonephenylhydrazone* (*c*). (*c*) was prepd. according to K. and S. By the action of HNO_3 in Et_2O (*c*) was always decompd. into anthraquinone and PhNHNH_2 but the latter was more or less completely oxidized, depending on the conditions, to $\text{PhN}(\text{NO}_2):\text{N}$. About 1 g. of (*c*) in 10 cc. Et_2O cooled with a freezing mixt. and treated with 20% of a 50% $\text{Et}_2\text{O-HNO}_3$ soln. were dild. in a few mins. with Et_2O to ppt. anthraquinone (0.6 g.). The filtrate treated with H_2O gave a soln. which with alk. β -naphthol soln. gave a slight reaction for $\text{PhN}(\text{NO}_2):\text{N}$. At higher temps. the quantity of the latter product formed increases. That PhNHNH_2 is easily oxidized to $\text{PhN}(\text{NO}_2):\text{N}$ in the presence of anthraquinone was shown by sep. expts. The *methyl ether* of (*c*) was obtained by the action of Me_2SO_4 on (*c*) in 30% NaOH + some EtOH . The Me ether treated in Et_2O with HNO_3 - Et_2O at room temp. seps. anthraquinone (m. 284-5°). The filtrate treated with H_2O , then neutralized with 30% NaOH and extd. with Et_2O gave a mixt. of bases from which PhNMeNH_2 was sepd. by prepg. its BzH deriv. (m. 102-3°). Only a little $\text{PhN}(\text{NO}_2):\text{N}$ is formed. If the temp. is kept down during the reaction not a trace of $\text{PhN}(\text{NO}_2):\text{N}$ is formed but a yellow-red cryst. compd. seps. This compd. $\text{C}_{21}\text{H}_{18}\text{N}_2\text{O}_3$ is nearly insol. in EtOH and Et_2O but crysts. from CHCl_3 as orange-red leaves with a gold reflex, m. 240-1° (decompn.), sol. in concd. H_2SO_4 with a red-brown color but is repptd. on dild.; it is insol. in alk. hydroxides even in the presence of EtOH or Me_2CO which indicates that it is a deriv. of the ether (*c*). Hydrolyzed by boiling concd. HCl it gives anthraquinone (m. 283-5°). The acid filtrate treated with NH_4OH seps. a base, $\text{C}_7\text{H}_8\text{N}_2\text{O}_4$,

as yellow needles, m. 142° , which is probably $O_2NC_6H_4NMeNH_2$. The position of the NO_2 has not yet been detd. for lack of material. This hydrolysis shows that the NO_2 deriv. (m. $240-1^{\circ}$) is (III). The formation of this compd. containing NO_2 in the aromatic nucleus by the action of HNO_3 on (c) is a new proof of the greater resistance offered by the quinonic group to the action of HNO_3 as compared with the aromatic nucleus.

E. J. WITZEMANN.

The transformation of the nitrates of arylhydrazines into aryldiazonium nitrates through the action of nitric acid. G. CHARRIER. Univ. Torino. *Gazz. chim. ital.* 45, I, 516-28(1915); *Atti accad. sci. Torino* 50, 589-605(1915).—In the preceding paper it was shown that HNO_3 in Et_2O acting on anthraquinonephenylhydrazine gives anthraquinone + $PhNHNH_2$ and more or less $PhN(NO_2):N$. Later in repeating this test with arylhydrazine nitrates (i. e., in the absence of quinone), a small amt. of $PhN(NO_2):N$ was formed but the reaction is different in the absence of anthraquinone. C. has studied the influence of anthraquinone on this reaction and decided that it is due simply to an acceleration of the reaction. Equimol. amts. of other quinones (*p*-benzoquinone, thymoquinone, 1,2-naphthoquinone, phenanthrenequinone and acenaphthenequinone), acting on $PhNHNH_2.HNO_3$, *o*-, *m*-, *p*- $CH_3C_6H_4NHNH_2.HNO_3$ and the nitrates of *asym-m*-xylylhydrazine, *s*-pseudocumylhydrazine and *p*-anisyl- and *p*-phenetylhydrazine were studied. These expts. make it possible to det. whether the formation of aryldiazonium nitrates is connected with diazo scission, i. e., whether the 1st effect of the quinone on arylhydrazines is an oxidation of this into diazonium nitrate, accompanied by a contemporary reduction of the quinone to phenol and then the formation of the hydroxyazo compd. nitrate, which then by diazo scission could easily give the aryldiazonium nitrate. *p*-Benzoquinone oxidizes $PhNHNH_2$ with the evolution of N, oxidizes *asym*-alkylphenylhydrazine to tetrazones, reacts with *o*-nitro- and *o,p*-dinitrophenylhydrazine to give *p*-hydroxyazo compds. Thymoquinone gives arylhydrazones with arylhydrazines; β -naphthoquinone and phenanthrenequinone give *o*-hydroxyazo compds.; of anthraquinone and acenaphthenequinone the former does not react directly with $PhNHNH_2$ and the latter forms arylhydrazones with arylhydrazines (C. A. 5, 877). The transformation of arylhydrazine nitrates into aryldiazonium nitrates with HNO_3 in Et_2O proceeds differently in the presence or absence of quinones. The quinones negatively catalyze the effect of the HNO_3 , but nitrous vapors are always evolved. When the quinones are excluded the reaction is violent and red gases are rapidly evolved, due no doubt to the oxidation of arylhydrazine by HNO_3 . Such actions may be written thus: $ArNHNH_2.HNO_3 + 2HNO_3 \longrightarrow N_2O_5 + 3H_2O + Ar(NO_2):N$ or $2ArNHNH_2.HNO_3 + 2HNO_3 \longrightarrow 2ArN(NO_2):N + 5H_2O + N_2O$, etc. Further the arylhydrazines can react with the diazonium salts thus: $PhN_2NO_3 + PhNHNH_2.HNO_3 \longrightarrow PhN_2$ (diazobenzeneimide) + $PhNH_2.HNO_3$ and the latter may react to give so-called "buzylenic" derivs., $PhN:NNPhNH_2$ or $PhN(:N)NPhNH_2$. In the presence of quinones HNO_3 acts on arylhydrazines with almost no gas evolution. With β -naphthoquinone and thymoquinone the primary product is the hydroxyazo compd. nitrate which by diazo scission gives the diazonium nitrate and $O_2NC_6H_4OH$. With anthraquinone the effect on the reaction is relatively slight and nitroanthranol was not found, which was as expected since the arylhydrazine of anthraquinone is decompd. by HNO_3 into anthraquinone and arylhydrazine and the latter is readily oxidized to aryldiazonium nitrate. *p*-Benzoquinone, phenanthrenequinone and acenaphthenequinone have no effect on the action of HNO_3 on arylhydrazine. The action of HNO_3 in Et_2O on arylhydrazine nitrates and β -naphthoquinone and thymoquinone with the primary formation of 2-arylaazo-1-naphthol and 6-arylaazothymol nitrates is a new confirmation of the theory on the mechanism of the Population that admits the intermediate formation of hydroxyazo compds.

(C. A. 8, 81; 9, 1316) and that permits as possible the formation of hydroxyazo compds. from quinones and arylhydrazines. The formation of hydroxyazo compds. from quinone and arylhydrazines may be considered as possible not through an intramol. change of the quinone hydrazone first formed but by oxidation of the arylhydrazine salt to the diazonium salt by the quinone which is thus reduced to phenol, and copulation of the diazonium salt with phenol with the intermediate production of the hydroxyazo salt compd. according to the scheme previously proposed (C. A. 9, 1316). Attempts to isolate arylhydrazine nitrates containing 2 equivs. of HNO_3 (like $\text{PhNHNH}_2 \cdot 2\text{HF}$) failed. Contrary to statements in the literature arylhydrazine nitrates are quite stable. Some new ones were prepared. 2.16 g. PhNHNH_2 dissolved in 120 cc. CHCl_3 , cooled, treated gradually with 40 cc. of Et_2O containing 20 cc. HNO_3 and heated on a bath under a condenser sepd. $\text{PhNHNH}_2 \cdot \text{HNO}_3$ which redissolves with the evolution of red fumes. The liquid shaken with H_2O gives a soln. which with β -naphthol ppts. phenylazo- β -naphthol, showing the presence of much $\text{PhN}(\text{NO}_2):\text{N}$. The other hydrazines mentioned above similarly treated gave much nitrous vapors and the corresponding diazonium salts as shown by their derivs. with β -naphthol. 6.48 g. *p*-benzoquinone in 240 cc. CHCl_3 treated gradually with 120 cc. of the HNO_3 - Et_2O mixt. and heated on the H_2O bath developed no red vapors and gave a negative test for $\text{PhN}(\text{NO}_2):\text{N}$. Similar results were obtained with *p*-tolylhydrazine and *asym-m*-xylylhydrazine. The *p*-benzoquinone prevents the existence of aryl diazonium nitrate. Using an equiv. amt. of thymoquinone the above was repeated. White crystals of $\text{PhN}(\text{NO}_2):\text{N}$ sepd. which in alk. soln. with β -naphthol ppts. phenylazo- β -naphthol. The Et_2O - CHCl_3 soln. was washed with 5% NaOH ; the ext. gave on adding H_2SO_4 a ppt. of 6-nitrothymol (*a*), m. $140-2^\circ$. But (*a*) is formed normally in the diazo scission of 6-phenylazothymol nitrate so that the reaction must be thus: $\text{thymol} + \text{PhN}(\text{H} \cdot \text{NO}_2)\text{HNH}_2 \cdot \text{HNO}_3 \rightarrow (\text{I}) \rightarrow (\text{a}) + \text{PhN}(\text{NO}_2):\text{N} + \text{H}_2\text{O}$. A mol. equiv. amt.

of β -naphthoquinone similarly treated and warmed gently became wine-red (2 phenylazo-1-naphthol nitrate) and then the color diminished and white $\text{PhN}(\text{NO}_2):\text{N}$ sepd. as was shown by the β -naphthol test. The Et_2O - CHCl_3 soln. treated as above gave 2-nitro-1-naphthol, m. $127-8^\circ$. In this case the intermediate formation of 2-phenylazo-1-naphthol was observed. The reaction is similar to the preceding. Similar results were obtained by using equiv. amts. of *o*- and *p*- $\text{MeC}_6\text{H}_4\text{NHNH}_2$, *asym-m*-xylylhydrazine and *s*-pseudocumylhydrazine instead of PhNHNH_2 . Treating 2.16 g. $\text{PhNHNH}_2 + 4.16$ g. anthraquinone with 120 cc. CHCl_3 and 60 cc. of Et_2O - HNO_3 mixt. on the H_2O bath evolved a trace of nitrous gas, and gave on dilg. with Et_2O unchanged anthraquinone and a little $\text{PhN}(\text{NO}_2):\text{N}$ but no nitroanthrol nor its tautomer nitroanthrone. With the other hydrazines analogous results were obtained. Under similar conditions PhNHNH_2 with phenanthrenequinone or acenaphthenequinone a trace of $\text{PhN}(\text{NO}_2):\text{N}$ was formed and the tumultuous reaction in the absence of the quinones is impeded by mol. amts. of the quinones. Small amts. of the quinone are without effect in all these cases. A dil. Et_2O soln. of PhNHNH_2 acting on Et_2O - HNO_3 seps. phenylhydrazine nitrate, $\text{PhNHNH}_2 \cdot \text{HNO}_3$, fine white needles, m. $145-6^\circ$, decomp. $185-90^\circ$. *o*-Tolylhydrazine nitrate, large white leaves, m. $98-100^\circ$; *m*-compound, white needles, m. $145-7^\circ$ (contract); *p*-compound, shining white leaves, m. $152-3^\circ$; *asym-m*-xylylhydrazine nitrate, splendid white laminas, m. $146-7^\circ$ (decompn.); *o*-anisylhydrazine nitrate, gel-

atinous mass, very sol. in H_2O , m. 108° (decompn.); *p-anisylhydrazine nitrate*, colorless prismatic needles, discolors in the light, m. $95-6^\circ$ (decompn.); *p-phenetylhydrazine nitrate*, white leaves, become rose-colored in the light and air, m. $107-8^\circ$ (decompn.).

E. J. WITZEMANN.

Thiosaccharin. ANNA MANNESSIER. Univ. Pavia. *Gazz. chim. ital.* **45**, I, 540-52 (1915).—In preceding papers (*C. A.* **5**, 1090; **9**, 72, 73) it was shown that P_2S_5 acting on the CO group in camphorimide, $C_8H_{14}(CO)_2NH$, and chlorocamphorimide, $C_8H_{13}Cl(CO)_2NH$, give thiocamphorimide, $C_8H_{14}(CS)_2NH$, and thiochlorocamphorimide $C_8H_{13}Cl(CS)_2NH$, resp. M. has studied the action of P_2S_5 on an imide derived from a group different from the 2 preceding, i. e., saccharin, in order to obtain the thio deriv. When a mixt. of saccharin and P_2S_5 is heated to 220° a good yield of thiosaccharin (*a*) is obtained as intense yellow crystals, m. 180° . The constitutional

formula was demonstrated by the action of hydrolyzing agents: $C_4H_4 \begin{array}{c} \diagup CS \diagdown \\ \diagdown SO_2 \diagup \end{array} NH +$

$H_2O \longrightarrow C_4H_4 \begin{array}{c} \diagup CO \diagdown \\ \diagdown SO_2 \diagup \end{array} NH + H_2S$. Prolonged boiling with H_2O evolves H_2S and on

cooling seps. crystals of saccharin. Alk. carbonates give a yellow soln. with (*a*) in the cold which, acidified, seps. (*a*) unchanged; when boiled, however, the color is intensified and on acidifying H_2S is evolved and a mixt. of saccharin + (*a*) ppts. Alk. hydroxides give with (*a*) in the cold an orange-yellow soln. which when acidified evolves H_2S and seps. a mixt. of saccharin and (*a*); when heated the alk. mixt. is decolorized slowly. The cool decolorized soln. acidified with H_2SO_4 seps. crystals of $HO_2CC_4H_4SO_2NH_2$ slowly. Thus the action of alkalis on (*a*) takes place in 2 stages: (*a*) $\longrightarrow$ saccharin $\longrightarrow HO_2CC_4H_4SO_2NH_2$. The last is also formed by the action of NaOH on saccharin (Wilson, *Chem. Zentr.* **1904**, I, 276). In either hot or cold NH_4OH (*a*) dissolves with a yellow coloration and ppts. (*a*) unchanged on acidifying. Dil. HCl does not dissolve (*a*) in the cold, but dissolves it slowly on prolonged heating, giving a yellow soln. and evolving H_2S ; finally decoloration becomes complete. Evapd. on the H_2O bath a sirup is obtained from which $HO_2CC_4H_4SO_2NH_2$ seps. (The same result is obtained on boiling saccharin with HCl (Krannich, *Ber.* **33**, 3485).) In this case (*a*) $\longrightarrow$ saccharin $\longrightarrow HO_2CC_4H_4SO_2NH_2$. (*a*) like saccharin behaves like an acid owing to the presence of imide H between 2 negative groups. Using NH_4 thiosaccharinate, which was isolated and analyzed, salts of heavy alk. and alkaline earth metals were prepd. Attempts to obtain other derivs. of (*a*) by substituting the imide H with different radicals failed in general because of its easy transformation into saccharin, the derivs. of which were obtained. MeI reacting with (*a*) in EtOH in the presence of KOH in the hot is completely transformed into saccharin. Boiling (*a*) with dry C_6H_6 in the presence of Me_2SO_4 gives a mixt. of *methylthiosaccharin* with much saccharin. Acetylation of (*a*) with Ac_2O gives acetylsaccharin. (*a*) treated with C_4H_9N in the cold gave *pyridine thiosaccharate* with the evolution of heat and a trace of H_2S . This salt is sol. in excess of C_4H_9N and on boiling eliminates H_2S ; on dilg. with H_2O was pptd. a small amt. of a yellow-brown, basic N compd., m. 260° , which is to be studied further. Concd. HNO_3 reacts on (*a*) in the cold, giving a NO_2 deriv., of which the study was not completed because of the lack of accurate knowledge about NO_2 derivs. of saccharin. (*a*) is not the only possible product of the action of P_2S_5 on saccharin; a small amt. of an intensely red compd. free from N, m. 98° , was sepd.; this may become the principal product of the reaction when the conditions are properly changed as will be shown in another paper. *Prepn. of (a)*: Equimol. amts. of finely triturated saccharin and P_2S_5 were heated slowly in a metal bath. At 180° H_2S is evolved and a light sublimate

seps. on the walls of the vessel. The browning proceeds from the edge toward the center and at 220° is complete and the mass is transformed into a yellow liquid. If it is desired to obtain a large yield of (a) no further rise in temp. is permissible. If the mass resolidifies a small deflagration and a violent instantaneous reaction take place and the N-free red compd. is the principal product. The product obtained by heating up to 220° is repeatedly extd. by boiling with C_6H_6 and on distg. off the C_6H_6 (a) is sepd. Using 2 g. saccharin at a time the yield may be 90%. (a) may be crystd. from most org. solvents. The red compd. is sol. in the same solvents and its formation must be avoided in order to obtain pure (a) easily. (a) is bitter and mixed with an equal amt. of saccharin has a mild taste. An excess of (a) treated in the cold with concd. NH_4OH , then filtered and the NH_4OH allowed to evap., sepd. *ammonium thiosaccharinate*, C_6H_4  $N.NH_4$, as yellow needles, sol. in H_2O . The NH_4 salt treated with

$Cu(OAc)_2$ gave a brown, with $Pb(OAc)_2$ a white, with $FeCl_3$ a yellow, with salts of the alk. earths white, with salts of the alk. metals straw-yellow ppts. With $AgNO_3$ the NH_4 salt ppts. the yellow *silver salt*, m. 250.5° , blackens in the light; $HgCl_2$ ppts. the *mercury salt* as a white cheesy ppt. that blackens in the light; the NH_4 salt treated with concd. $NaCl$ soln. ppts. the *sodium salt* as straw-yellow scales. 2 g. (a) dissolved in C_6H_6 boiled with 3.8 g. dry Me_2SO_4 under a condenser for 3 hrs. darkened and on cool-

ing sepd. *methylthiosaccharin* C_6H_4  NMe , as colorless prismatic needles; re-

crystd. from $EtOH$ and then C_6H_6 it m. 221° . A further quantity was sepd. by adding dry Et_2O . It is insipid to the taste. The yield is small. Much saccharin is formed and some (a) is recovered unchanged.

E. J. WITZEMANN.

The aromatic nitro derivatives: solubility of some nitro derivatives of toluene and of benzene in the solid state. IV. MICHELE GIUA. Univ. Milan. *Gass. chim. ital.* 45, I, 557-66(1915).—In a preceding paper (*C. A.* 10, 598) in examg. some binary mixts. of NO_2 derivs. of $PhMe$ that form the "oil of drainage" obtained in the prepn. of 2,4- $(NO_2)_2C_6H_3Me$, G. observed the formation of addition compds. completely dissociated in the liquid state. This result together with the contradictory behavior of NO_2 derivs. toward various solvents has compelled G. to continue the study of other NO_2 derivs. of $PhMe$ and C_6H_6 . In the nitration of many NO_2 compds. it often happens when 2 or 3 compds. are formed simultaneously that the purification by fractional crystn. is long and laborious. Thus in nitrating $m-O_2NC_6H_4Me$ to obtain the di- NO_2 deriv. the oily product contains at least 3 di- NO_2 derivs. that are difficult to sep. by ordinary means. Beilstein and Kuhlberg (*Ann.* 155, 25(1870)) sepd. the γ -isomer (3,4- $(O_2N)_2C_6H_3Me$, m. 60°) which Häussermann and Grell (*Ber.* 27, 2220(1894)) could not sep. but which together with the 3,5-deriv., was sepd. as the benzoic acid derivs. after oxidation. The union in such a mixt. is more intimate than the purely physical one of mixing. Of the binary systems reported here only that between α - and γ -trinitrotoluene is a clear case of the formation of a compd. dissociated in the liquid state. In this system because of the slowness in the formation of the compd. there is a metastable field that persists up to the intersection of the 2 arms of the curve, which does not correspond to the eutectic mixt., since the system shows 2 eutectic points considerably above the f. p. of this pt. of intersection. The part of the curve that belongs to the compd. lies nearly parallel to the axis of abscissas, is without a pronounced max. and extends through an interval of about 15% in the concn. (i. e., from 30 to 45% of the γ -deriv.). 3 other systems, $p-O_2NC_6H_4Me$ -2,6- $(O_2N)_2C_6H_3Me$, $p-O_2NC_6H_4Me$ -2,4,6- $(O_2N)_3C_6H_2Me$ and 2,4,6- $(O_2N)_3C_6H_2Me$ -1,3- $(O_2N)_2C_6H_4$, show the same char-

acteristic curve but the line parallel to the axis of abscissas is much more limited. It was not possible to det. by thermal analysis what compn. corresponds to the compd. The existence of a region, however limited, parallel to the axis of abscissas, arguing thermodynamically, is to be ascribed to the formation of an addition compd. The curves for the system, $p\text{-O}_2\text{NC}_6\text{H}_4\text{Me-1,3-C}_6\text{H}_4(\text{NO}_2)_2$, $2,4\text{-(O}_2\text{N)}_2\text{C}_6\text{H}_3\text{Me-1,3-C}_6\text{H}_4\text{-(NO}_2)_2$, $p\text{-O}_2\text{NC}_6\text{H}_4\text{Me-NHPh}_2$ show a simple eutectic. The latter system is of interest in the explanation of the behavior of NO_2 derivs. toward NHPh_2 . Many NO_2 derivs. as $p\text{-O}_2\text{NC}_6\text{H}_4\text{Me}$, the nitrotoluenes, the dinitrotoluenes, $1,3\text{-C}_6\text{H}_4(\text{NO}_2)_2$, tetranitromethylaniline, hexanitrodiphenylamine and various nitrobenzoic acids give in the hot, with NHPh_2 even in dil. solns., a red-yellow coloration which disappears slowly with cooling. This behavior suggested the possibility of the existence of such association compds. with NHPh_2 , but the fact that the system $p\text{-O}_2\text{NC}_6\text{H}_4\text{Ph}_2\text{-NHPh}_2$ behaves normally in every way excludes an interdependence between this coloration and a hypothetical compd. The study of this part relating to the NHPh_2 system will be continued. For 5 systems the f. p. method was used and the thermic method for the 2 others. 10 g. of the mixt. was used in each expt. The curves and numerical data are given in the original. The system α - and γ -trinitrotoluene shows the formation of an addition compd. between 3 mols. of the α - and 2 mols. of the γ -derivs. The eutectic between the α -deriv. and the compd. lies at 56.75° ; that with the γ -deriv. and the compd. at 58.2° . With $p\text{-O}_2\text{NC}_6\text{H}_4\text{Me-2,6-O}_2\text{NC}_6\text{H}_3\text{Me}$ for 3 mols. of the 1st and 2 of the 2nd the m. p. of the compd. (compn. not detd.) and that of the eutectic between the compd. and the 1st coincide. With $p\text{-O}_2\text{NC}_6\text{H}_4\text{Me-(O}_2\text{N)}_2\text{C}_6\text{H}_3\text{Me}$ the parallel part of the curve covers 5% in compn. and corresponds to a compd. between 3 mols. of the 1st and 2 of the 2nd, as in the preceding system. With $\alpha\text{-(O}_2\text{N)}_2\text{C}_6\text{H}_3\text{Me-1,3-C}_6\text{H}_4(\text{NO}_2)_2$ an addition compd. between 1 mol. of each is formed which is dissociated into its components in the liquid state. The system $p\text{-O}_2\text{NC}_6\text{H}_4\text{Me-1,3-C}_6\text{H}_4(\text{NO}_2)_2$ shows a eutectic with 2 f. ps., the final f. p. being 29.5° ; the system $2,4\text{-O}_2\text{NC}_6\text{H}_3\text{Me-1,3-C}_6\text{H}_4(\text{NO}_2)_2$ shows a eutectic with 2 f. ps., the latter one being at 42.9° . The system $p\text{-O}_2\text{NC}_6\text{H}_4\text{Me-NHPh}_2$ shows a eutectic that f. 18.5° . Very small amts. of the 1st compd. give the rose-yellow color characteristic of the system. Cf. C. A. 9, 1479, 2089.

E. J. WITZEMANN.

Mixtures of explosive nitrates and the nitration of toluene. MICHELE GRUA. Milan. *Gazz. chim. ital.* 45, II, 32-44(1915).—Picric acid has long been used in explosives as the Na or NH_4 salt in mixts. with other NO_2 derivs. These mixts. always have a lower m. p. than either component and are used primarily in order to avoid certain grave inconveniences in the fusion and compression of pure $\text{C}_6\text{H}_3(\text{NO}_2)_3\text{OH}$. Thus Girard states that the following mixts. are used as explosives: (1) the mixt. 1 mol. $\text{C}_6\text{H}_3(\text{NO}_2)_3\text{OH}$ (m. 122°) + 1 mol. nitronaphthalene (m. 61°), m. 49° ; (2) a similar mixt. with dinitrotoluene (m. 71°) m. 47° ; (3) with trinitrocresol (m. 107°), m. 70° ; 2 mols. $\text{C}_6\text{H}_3(\text{NO}_2)_3\text{OH}$ + 1 mol. trinitrocresol, m. 78° . The latter mixt. is called "Kresylite" and the cresol deriv. renders the picric acid less dangerous and more resistant to shock. With the substitution of trinitrotoluene (a), for picric acid the use of the former in mixts. also was largely extended. Thus "plastrotyl" of Bichel (*Ger. Pat.* 193213 (1906)) is a resinous mixt. of tri-, mono- and dinitrotoluene; plastic trinitrotoluene (Rudeloff, *Ger. Pat.* 201306(1906)) for grenades and torpedoes is a mixt. of (a), dinitrotoluene gelatinized with collodion cotton, KClO_3 and $\text{Pb}(\text{NO}_3)_2$; "macarite" is a mixt. of 4 mols. of (a) and 7 mols. $\text{Pb}(\text{NO}_3)_2$; "yonckite" (Dautriche, C. A. 8, 1208) is a mixt. of 20% (a), 20% NH_4ClO_4 , 27% NaNO_3 and 6% $\text{Pb}(\text{NO}_3)_2$; "ammonal" used in the Austrian army and navy is a mechanical mixt. of (d), NH_4NO_3 , C and Al. Nitroaromatic compds. that have recently become important are tetranitromethylaniline (b) or trinitromethylnitroaminobenzene, tetranitroaniline (c)

(Flürscheim, Simon, *Chem. News*, 1910, 218) and hexanitrodiphenylamine (d) or *p*-picrylamine. (b) and (c) are used as detonators in caps. Not much is known about the use of (d). In its acid properties and sensibility it resembles picric acid, but in its explosive power stands between picric acid and (a). Mixts. of (a) and (d) may have practical interest and such mixts. together with some other systems were studied. In mixts. of (a) and (b) ranging from 100% to 48% of (a) the initial f. p. and eutectic temp. indicate the formation of an addition compd. of 3 mols. (a) with 2 mols. of (b) which dissociates at the m. p. The eutectic lies at 65.5–66°. In the system *p*-O₂-NC₆H₄Me–(b) there is a eutectic with 2 f. ps. very close together, a case which is well known. The system (a)–(d) even with small concns. of (d) is strongly canary-yellow in color. The small lowering in the f. p. is attributed to the formation of solid solns. **Nitration of PhMe:** After reviewing the nitration of PhMe G. gives the results of Van der Arend (*Chem. Zentr.* 1908, I, 2092) in which it was shown that the ratio of *o*-, *m*-, and *p*-O₂NC₆H₄Me varies somewhat with the temp. of nitration. In 4 nitrations at –30°, 0°, 30° and 60°, resp., the initial f. p. decreased from 4.1° to –0.8°. The formation of dinitrotoluene is discussed historically. Recently Silks (*Rec. trav. chim.* 27, 208(1907)) found that nitrating *m*-O₂NC₆H₄Me gives 3,4-, 2,3- and 2,5-(O₂N)₂C₆H₃Me, which agrees with the results of Hepp (*Ann.* 215, 366(1882)), Will (*C. A.* 8, 1590) and G. (*C. A.* 9, 2089). Blanksma (*Rec. trav. chim.* 25, 165(1905)) and Will (*C. A.* 8, 1590) have found that 3,5-(O₂N)₂C₆H₃Me cannot be further nitrated. Thus direct nitration of PhMe can only give (α) 2,4,6-, (β) 2,3,4- and (γ) 3,4,6-(O₂N)₃C₆H₂Me and only indirectly through dinitrotoluidine can the other 3, namely, 3,4,5-, 2,3,5- and 2,3,6-(O₂N)₃C₆H₂Me, be obtained (Körner, Contardi, *C. A.* 9, 1478, 3218). The direct nitration of PhMe to (O₂N)₃C₆H₂Me is of interest from a technical point of view and gives principally 2,4-O₂NC₆H₃Me and considerable of a yellow "oil of drainage" composed of *m*- and *p*-O₂NC₆H₄Me, various dinitro- and at least α- and γ-trinitrotoluene. Nitration expts. were done with mixts. of HNO₃, H₂SO₄ and H₂O in varying proportions used with varying amts. of PhMe. The wt. of the solid product and the oil drained off, the f. p. of the solid, etc., are given in the table (cf. original). The same method of nitration was used for all, i. e., the PhMe was added to the acid-H₂O mixt. a little at a time with constant agitation and the temp. controlled with a thermometer in the mixt. The f. p. of the crude solid product was taken after draining off the oil at 35–40°. The solid product could be further nitrated to (O₂N)₃C₆H₂Me with anhydrous H₂SO₄-HNO₃ mixts. containing 18–30% HNO₃. The results indicate an analogous condition for the di-NO₂ deriv. as that found by V. d. Arend for the com. mononitrotoluene.

E. J. WITZEMANN.

The glucoside of *m*-hydroxybenzaldehyde. G. BARGELLINI AND R. DE FAZI. *Gazz. chim. ital.* 45, II, 10–2(1915).—Jowett (*J. Chem. Soc.* 77, 707) extd. a glucoside different from salicin from the black bark of *Salix discolor* which he called *salinigrin*, white crystals, m. 195°, $[\alpha]_D^{15}$ –87° 3', and which on hydrolysis gave *m*-HOC₆H₄CHO, indicating that the parent compd. is a glucoside of *m*-HOC₆H₄CHO. Since Mauthner (*C. A.* 7, 772) synthesized the glucoside of *o*- and *p*-HOC₆H₄CHO it was thought of interest to obtain the *m*-deriv. This paper is a preliminary report. 4 g. *m*-HOC₆H₄CHO in 30 cc. of *N* NaOH and 30 cc. H₂O and 10 g. acetobromoglucose in 60 cc. Et₂O were agitated for 2–3 days. The liquid, if not alk., was made alk. The Et₂O evapd. in dry air and the semisolid residue crystd. from Me₂CO + H₂O(1:1) sepd. discolored crystals of the *m*-hydroxybenzaldehyde glucoside tetraacetate, m. 103–7°, $[\alpha]_D^{25}$ –43° 22', sol. in cold EtOH, C₆H₆ and Me₂CO. Attempts to hydrolyze this compd. with Ba(OH)₂ under the accepted conditions gave a resinous oil. It is expected that repetition under better conditions will give a deriv. identical with saligrin.

E. J. WITZEMANN.

Azohydroxamic acids. I. G. PONZIO. Univ. Sassari. *Gazz. chim. ital.* **45**, II, 12-29(1915).—The expts. here described were done in order to obtain derivs. of dinitrocarbonyl, O_2NCONO_2 . The analogy between $PhCH(NO_2)_2$ and $CH(NO_2)_3$ appears from their nitronic forms $Ph(NO_2)C:NOOH$ and $(O_2N)_2C:NOOH$. In the same way that the diazonium salt $Ph(NO_2)C:NOON_2Ph$ gave $Ph(NO_2)C:NNHC_6H_4NO_2$ (*C. A.* **2**, 2812; **5**, 693), P. expected $(O_2N)_2C:NO_2NPh$ to rearrange in moist Et_2O to the dinitrocarbonyl-*p*-nitrophenylhydrazine, $(O_2N)_2C:NNHC_6H_4NO_2$, but a product of decompn., *phenylazoformhydroxamic acid* (a), $PhN:NC(:O)NHOH$, was obtained which is the 1st term of a new series of compds. The reaction may be $(O_2N)_2C:NO_2N_2Ph + 2H_2O \longrightarrow (a) + 2HNO_3$. But P. considers that the behavior of this salt is similar to that of the *p*-substituted aryldiazonium salts of $Ph(NO_2)C:NO_2N_2ArX$ ($X = Cl, Br, Me, NO_2$, etc.) which in moist Et_2O rearrange into benzoylarylnitrosohydrazines, $PhC(:O)N(NO_2)N(NO)ArX$, which lose N_2O_2 spontaneously to give benzoylazoaryls, $PhC(:O)N:NArX$, as the final product (*C. A.* **5**, 685, 686; **8**, 2692). Thus analogously $(O_2N)_2C:NO_2N_2Ph$ probably isomerizes into nitrocarbonylphenylnitro-nitrosohydrazine (b), $ON_2CON(NO_2)N(NO)Ph$, which gives nitrocarbonylazophenyl, $O_2NCON:NPh$, and by this reduction gives (a). It is also possible as was shown with the Bz deriv. (*C. A.* **2**, 2812, **5**, 686) that 2 H_2O acting on (b) gives $O_2NC(:O)NHNHPh + HNO_2 + HNO_3$ which explains the formation of the acids, but the oxidation of the hydrazo group of the latter to azo and the reduction of NO_2 to $NHOH$ can not take place with only H in the mol., and ought to be attributed to 2 other reactions. According to Bamberger and Rust (*Ber.* **35**, 45 (1902)) $HCHNOOH$ gives $HC(:O)NHOH$, and thus phenylazonitromethane (c), $PhN:NCHNO_2H$, should give (a) and it would have to be that $PhN(Ac):N$ acting on $CH(NO_2)_3$ would not give a diazonium salt, as was found, but $PhN:NC(NO_2)_3$, which by the action of H_2O would give $PhN:NCH_2NO_2$ and this (c) and, by rearranging, (a). This does not seem logical. It was found that other aryldiazonium salts of $CH(NO_2)_3$ react the same way in moist Et_2O to give $HOHNC(:O)N:NAr$ but P. has limited himself in this paper to the Ph deriv. and the discussion of reasons for attributing formula (a) to it instead of that of the tautomer phenylazoformhydroxamic acid, $PhN:NC(OH):NOH$. The formula (a) explains all the properties of this compd. and above all its transformation into phenylazide, $PhN:N:N$, a reaction which is common to all members of the series and which constitutes a good new method of prepn. of the arylazides, $ArN:N:N$ or $ArN.N:N$. In this

reaction 1 mol. (a) gives $PhN:N:N + CO_2 + H_2$, a reaction which is similar to the prepn. of HN_3 from azodicarbonamide (d): $H_2NCON:NCONH_2 + 2O \longrightarrow HN_3 + 2CO_2 + NH_3$; and of PhN_3 from phenylazocarbonamide, (e): $PhN:NCONH_2 + 2O \longrightarrow PhN:N:N + CO_2 + N_2O$ (*C. A.* **1**, 2479). In the case of (d) P. explains the reaction by admitting that triazenecarboxamide $H_3NCON:NNH_2$ is formed and tautomerizes into cyclotriazane, $H_3NCON.NH.NH$, which is oxidized to the azide.

$H_2NCON.N:N$, and sapond. to give HN_3 . A similar explanation was used for (e).

In (a) as well as (d) and (e) the CO group is eliminated as CO_2 . Urea, (d) and (e) however do not give N_2 , HN_3 and PhN_3 with alkalis alone but only when $NaOCl$ or $NaOBr$ is present which oxidizes carbonyl to CO_2 while with (a) the CO_2 is formed by intramol. oxidation in the presence of alkali alone. There is not enough O however to oxidize the H intramol. so that it is evolved. Thus (a) behaves like a hydroxyurea deriv. Hydroxyurea, according to Conduché (*C. A.* **2**, 658, 999), exists in 2 forms: (1) $H_2NCONHOH$ and (2) $H_2NC(OH):NOH$. (1) gives no color with $FeCl_3$ and gives a HCl salt; (2) gives an intense blue color with $FeCl_3$ and forms metallic salts. Since (a) behaves like (1) this is further confirmation of the formula. These expts. show the

marked difference in the behavior of MeNO_2 , $\text{CH}_2(\text{NO}_2)_2$ and $\text{CH}(\text{NO}_2)_3$ toward PhN_2OAc : $\text{MeNO}_2 \longrightarrow \text{O}_2\text{NCH:NPh}$; $\text{CH}_2(\text{NO}_2)_2 \longrightarrow (\text{O}_2\text{N})_2\text{C}(\text{N:NPh})_2$; and $\text{CH}(\text{NO}_2)_3 \longrightarrow \text{HOHNC}(\text{O})\text{N:NPh}$. A cold satd. aq. soln. of $(\text{NO}_2)_2\text{C:NO}_2\text{K}$ was added gradually with ice cooling to an equimol. amt. of PhN_2OAc in not too dil. aq. soln. A cryst. ppt. (the *phenyldiazonium salt of trinitromethane*) (*f*), $(\text{NO}_2)_2\text{C:NO}_2\text{N}_2\text{Ph}$, seps., which, washed well with H_2O , taken up in Et_2O and pptd. with Me_2CO , seps. as golden yellow crystals that explode easily. It is little sol. in cold and more sol. in hot H_2O ; the yellow soln. decomps. with the evolution of N_2 , but with care most of (*f*) can be recovered by quickly cooling the soln. made at $50-60^\circ$. It is insol. in cold EtOH , Et_2O , CHCl_3 , C_6H_6 , and ligroin but quite sol. in Me_2CO . Boiled with H_2O it evolves nitrous vapors and resinifies; boiled with Et_2O it gives AcH . That (*f*) is $(\text{NO}_2)_2\text{C:NO}_2\text{N}_2\text{Ph}$ and not phenylazotritromethane, $(\text{NO}_2)_3\text{CN:NPh}$, is shown (1) by the action of H_2O which gives $\text{CH}(\text{NO}_2)_3$, PhOH and N_2 quant.; (2) by adding 35% HCl gradually to the compd. while cooling, which gives PhNCl:N and $\text{CH}(\text{NO}_2)_3$, of which the former was recognized by giving phenylazo- β -naphthol with β -naphthol, and the 2nd as the salt of nitron obtained by the action of an aq. soln. of $(\text{NO}_2)_2\text{C:NO}_2\text{K}$ with the AcOH soln. of nitron 1,4-diphenyl-3,5-endanilodihydrotriazole. The *trinitromethane salt of nitron*, $\text{CH}(\text{NO}_2)_3 \cdot \text{C}_{10}\text{H}_{10}\text{N}_4$, is a yellow ppt. which crysts. from EtOH as golden yellow needles, m. 150° (decompn.). P. believes now that the product similarly obtained from $\text{PhCH}(\text{NO}_2)_2$ (C. A. 2, 2812; 5, 693) with PhN_2OAc is $\text{PhC}(\text{NO}_2)_2\text{N:NO}_2\text{N}_2\text{Ph}$, although some of its properties make $\text{PhC}(\text{NO}_2)_2\text{N:NPh}$ more probable; likewise the product obtained with $\text{PhCH}(\text{CN})\text{NO}_2$ must be phenylazophenylcyanonitromethane, $\text{PhC}(\text{CN})(\text{NO}_2)\text{N:NPh}$. When (*f*) is agitated in moist Et_2O in a cold H_2O bath it is gradually dissolved with the evolution of nitrous gases. The Et_2O soln. is carefully washed with a little H_2O and allowed to evap. in the air; (*a*) seps. as splendid white needles, m. $84-5^\circ$, sol. in EtOH , Et_2O , Me_2CO , C_6H_6 and CHCl_3 , sol. in H_2O but more sol. in H_2O containing inorg. acids or AcOH ; it reduces Fehling or $\text{Ag}_2\text{O-NH}_3$ soln. in the cold, sol. in concd. H_2SO_4 and is reprecip. on dilg.; CrO_3 in AcOH oxidizes it completely, but PCl_5 , PCl_3 , $\text{Br-H}_2\text{O}$, Ac_2O and KMnO_4 are without action; it gives no coloration with FeCl_3 or $\text{Cu}(\text{OAc})_2$; decomps. in alk. soln. as described above. Heated in the sealed tube at $175-80^\circ$ with fuming HCl it decomps., giving in part PhN_3 , PhNH_3 and NH_3 . The hydrazo deriv. of (*a*), PhNHNHCONHOH , could not be obtained by reduction. When (*a*) is suspended in abs. EtOH and EtOH-KOH added it dissolves and on acidifying later a yellow oil, which is to be studied further, sepd.; this may be *phenylazoxymethyldroxamic acid*, $\text{PhN:NC}(\text{OH})\text{:NOH}$. Heating (*a*) with HNO_3 (d. 1.52) on the H_2O bath and pouring on ice seps. *p*-nitrophenylazoxymethyldroxamic acid (*g*), $\text{O}_2\text{NC}_6\text{H}_4\text{N:NC}(\text{O})\text{NHOH}$, crysts. from EtOH as yellow needles, m. $165-6^\circ$, little sol. in EtOH and ligroin, more sol. in C_6H_6 and CHCl_3 , sol. in boiling H_2O , more sol. in dil. HNO_3 , sol. unchanged in concd. H_2SO_4 or HNO_3 . Some (*g*) is formed when (*f*) reacts too rapidly in moist Et_2O or if the Et_2O is distd. off on the H_2O bath. In this case the Et_2O residuc is extd. with petr. ether repeatedly in which (*g*) is insol. The formation of (*g*) proves that (*f*) gives rise to HNO_3 in its decompn. Heated with alkalis (*g*) decomps. thus: (*g*) $\longrightarrow$ *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{N}_3 + \text{CO}_2 + \text{H}_2$. The *p*-nitrophenylazide was sepd. by steam distn.; it crysts. from ligroin as yellowish laminas, m. $71-2^\circ$ (Bamberger, Renault, Ber. 30, 2288(1897)).

E. J. WITZEMANN.

The formation of azides. G. PONZIO AND G. CANUTO. Univ. Sassari. *Gazz. chim. ital.* 45, II, 29-31(1915).—It was stated in a preceding paper (C. A. 2, 2812; 5, 685) that acylarylnitrosohydrazines (*a*), $\text{ArN}(\text{NO})\text{NHCOR}$, are transformed by boiling H_2O into acylarylhydrazines, ArNHNHCOR , and HNO_2 . This reaction was generalized by Giovetti (C. A. 5, 694) and consists in replacing NO with H which ought to be favored by the presence of alkalis. But (*a*) heated with 20% NaOH gives $\text{ArN.N:N} +$

RCO_2H . The formation of ArN_2 confirms the position occupied by NO in the acylarylhydrazines and confirms what had been detd. in an indirect way. It also favors the cyclic formula for the arylazides. $\text{PhN}(\text{NO})\text{NHCHO}$ was prepd. according to Wohl (Ber. 33, 2759(1900)). Dissolved in 20% NaOH and distd. with steam it gives PhN_2 and a little PhNH_2 . The latter was eliminated by washing with HCl. The PhN_2 was nitrated (Tilden, J. Chem. Soc. 63, 257(1893)) and transformed into $p\text{-O}_2\text{NC}_6\text{H}_4\text{N}_2$, m. 71° (Bamberger, Renauld, Ber. 30, 2288(1897)). $\text{BrC}_6\text{H}_4\text{N}(\text{NO})\text{NHCHO}$ was prepared according to Giovetti, using 50% HCO_2H acid instead of 5%. This with 20% NaOH and steam distn. gave $p\text{-BrC}_6\text{H}_4\text{N}_2$ and some $p\text{-BrC}_6\text{H}_4\text{NH}_2$. $\text{PhN}(\text{NO})\text{NHAc}$ (Wohl and Schiff, Ber. 35, 1902(1902)) similarly treated gave only PhN_2 . Acetyl-*p*-bromophenylnitrosohydrazine, $p\text{-BrC}_6\text{H}_4\text{N}(\text{NO})\text{NHAc}$, was obtained by adding to $p\text{-BrC}_6\text{H}_4\text{NHNHAc}$ in 2 *N* NaOH the calcd. amt. of NaNO_2 and after cooling in a freezing mixt. acidifying with 2 *N* H_2SO_4 ; it was purified by pptg. from Et_2O with petr. ether and seps. as yellowish laminas, m. $108\text{--}10^\circ$ (decompn.); with concd. H_2SO_4 it gives a wine-red color; boiled with H_2O it evolves nitrous fumes and gives $p\text{-BrC}_6\text{H}_4\text{NHNHAc}$, m. 161° . Treated with 20% NaOH as above it gave $p\text{-BrC}_6\text{H}_4\text{N}_2$. $\text{PhN}(\text{NO})\text{NHBz}$ (Wosvinkel, Ber. 34, 2352(1901)) similarly treated gives PhN_2 . E. J. WITZEMANN.

Spontaneous oxidation in the presence of aldehydes. Isoxazolecaboxylic compounds containing anisic or cinnamic residues. MARIO BETTI AND SERGIO BERLINGOZZI. Univ. Siena. Gass. chim. ital. 45, II, 44-51(1915).—In a preceding paper (C. A. 10, 599, 600) the spontaneous oxidation of the benzylidene deriv. of phenyl- and methylisoxazolone in the presence of BzH was described, by which deriva. of isoxazolecaboxylic acid were obtained. These new expts. were done in order to det. if other aldehydes (anisic and cinnamic) have the same effect. In both cases the typical derivs were formed. B. and B. wished to learn whether under analogous conditions other compds. would undergo the same oxidation. Previously it had been suggested that under the action of $\text{NH}_3\text{-EtOH}$ the oxazolone ring opens to form the intermediate $\text{HON}:\text{CRC}(\text{CONH}_2):\text{CHPh}$ in which the 2 *H* atoms in italics are removed by the action of atm. O_2 favored by the presence of BzH . Attempts were made to see if $\text{HON}:\text{CMeCH}:\text{CHPh}$ (a), which differs by having H for CONH_2 , is transformed into γ -methyl- α -phenylisoxazolone, $\text{N}:\text{CMe.CH}:\text{CPh.O}$, which has been obtained in another way

(l. c.). The (a) was recovered unchanged in all cases. This result raised the supposition that the position in space of the $>\text{NOH}$ may impede the oxidation. In expts. with the *cis* and *trans* isomers of $\text{PhCH}:\text{CHCH}:\text{NOH}$ both were recovered unchanged. This will be taken up again in later papers. The anisalmethylisoxazolone (b), $\text{MeO-C}_6\text{H}_4\text{CH}:\text{C.CO.O.N}:\text{CMe}$ used was prepd. by treating $\text{AcCH}_2\text{CO}_2\text{Et}$ with a mol.

amt. of free NH_4OH and adding the anisaldehyde and boiling a few mins.; (b) seps. as S-yellow refractive crystals, m. 174° . (b) dissolved in cold $\text{NH}_3\text{-EtOH}$, treated with a little BzH and boiled under a condenser for 1 hr., seps. some unchanged (b) on cooling. The filtrate after standing several days imperfectly stoppered and adding $\text{NH}_3\text{-EtOH}$ redissolves the yellow compd. and seps. whitish crystals gradually. The amidomethoxyphenylmethylisoxazolecaboxylic acid (c), $\text{MeOC}_6\text{H}_4\text{C}:\text{C}(\text{CONH}_2)\text{CMe}:\text{N.O}$,

obtained, m. 195° , and is analogous to the other similar derivs. previously obtained. Boiled with NaOH it evolves NH_3 from which the Na salt is crystd. The Na salt with HCl gives the free acid, white ppt., m. 178° , sublimes without decompn. Benzalmethylisoxazolone in $\text{NH}_3\text{-EtOH}$ treated with anisaldehyde as above sepd. at first some (b), m. 174° . This treated again with the reaction mixt. behaved as above and sepd. (c), in a few days; some phenylmethylisoxazolecaboxylamide, m. 256° , was sepd. from the mother liquors. With anisaldehyde the oxidation is slow. Cim-

namalmethylisoxazolone, $\text{MeC:N.O.CO.C:CHCH:CHPh}$, was prepd. from cinnamal-

dehyde + $\text{MeC(:NOH)CH}_2\text{CO}_2\text{Et}$, and treated with $\text{NH}_3\text{-EtOH}$ + BzH gave *phenyl-ethylenemethylisoxazolecarboxamide*, $\text{MeC:N.O.C(CH:CHPh):C.CONH}_2$, pearly crys-

tals, m. $185-6^\circ$; free acid, obtained as above, m. $118-20^\circ$. E. J. WITZEMANN.

Pyrazo-oxazine and oxazo-oxazine. Two new types of bisheterocyclic derivatives with the naphthalinoid bond. MARIO BETTI. *Gazz. chim. ital.* 45, II, 75-81(1915).—Cyclic compds. even quite different in nature but containing —CH:C(OH)— (or $\text{—CH}_2\text{CO—}$) give place frequently to the formation of derivs. similar in structure, in the manner of their synthesis and in physical and chem. properties; e. g., β -naphthol and pyrazolone. The following derivs. which are analogous in structure and methods of formation are known: dinaphthol and dipyrazolone, benzalbinnaphthol and benzalbispyrazolone, methylenedinaphthol and methylenedipyrazolone, methenyldinaphthol and methenyldipyrazolone. Derivs. of other rings like isoxazolone are similar in this respect to β -naphthol. B. has tried the action of derivs. of pyrazolone and isoxazolone on aldehydes and primary amines. Open chain compds. containing —CH:C(OH)— give pyridine derivs. under these conditions by eliminating the enolic OH. With β -naphthol (*Gazz. chim. ital.* 30, *et seq.*) the enolic OH is not eliminated but the O enters a heterocyclic ring to give naphthoxazine (I). Methylphenylpyrazolone and methyl-

isoxazolone give pyrazoxazine (II) and oxazooxazine (III) in this way. In the reaction 1 mol. of the azolone, 2 mols. of the aldehyde and 1 mol. of the amine eliminate 2 H_2O and give (II) or (III). Mixing warm EtOH solns. of methylphenylpyrazolone, BzH and $\beta\text{-C}_{10}\text{H}_7\text{NH}_2$ gives an orange-red liquid from which sep. white crystals of benzalbis[methylphenylpyrazolone] (a), $(\text{MeC:N.NPh.CO.CH})_2\text{:CHPh}$, m. $165-6^\circ$

(Lachowicz, *Monatsh.* 17, 358(1896)). The filtrate on standing a few days seps. 2 kinds of crystals; these pressed and washed with NaOH to remove (a), washed with H_2O , and dissolved in EtOH , give white needles of (b), a deriv. of (II), $\text{C}_{24}\text{H}_{21}\text{ON}_2$, m. 227° , in which $\text{R(1)} = \text{Me}$, R(2) , R(3) , and $\text{R(5)} = \text{Ph}$ and $\text{R(4)} = \text{C}_{10}\text{H}_7$. On long boiling with concd. HCl it gives an incipient decompn. and some BzH . It is sol. in boiling Ac_2O but does not recryst. unchanged. In the synthesis of (I) (*Gazz. chim. ital.* 31, II, 173(1901)) the reaction was found to proceed in 2 stages. Attempts to obtain the intermediates for (II) in EtOH soln. failed. Mixing equimol. amts. of methylphenylpyrazolone and benzalnaphtylamine in C_6H_6 gives an orange-red liquid from which sep. (a) + yellow-rose crystals (m. $140-70^\circ$); the latter were freed from (a) by washing with NaOH . In attempting to purify in EtOH it was decompd. and (b), m. 227° , was pptd., and free pyrazolone and $\text{C}_{10}\text{H}_7\text{NH}_2$ formed. The yellow-rose crystals are probably the intermediate in question although they differ in some respects from the intermediate of (I). Benzalmethylisoxazolone in concd. EtOH soln. treated with BzH and $\beta\text{-C}_{10}\text{H}_7\text{NH}_2$ and boiled a few min. gave a cryst. paste of (c), a deriv. of (III), in which $\text{R(1)} = \text{Me}$, R(2) and $\text{R(4)} = \text{Ph}$ and $\text{R(3)} = \text{C}_{10}\text{H}_7$, white silky needles, m. 257° . (c) is very stable toward chem. reagents. The intermediate addition compd. in C_6H_6 soln. was not obtained. E. J. WITZEMANN.

Sitosterol and stigmasterol. A. HEIDUSCHKA AND H. W. GLOTH. Univ. Munich. *Arch. Pharm.* 253, 415-26(1915).—Sitosterol was first prepd. by Burian (*Monatsh.* 18, 551) from wheat and rye seedlings, later also by Windaus (*C. A.* 1, 1002; 2, 86)

from the fat of the calabar bean. According to W., its compn., as also that of cholesterol, is represented by $C_{27}H_{46}O$, while B. advocated the formula $C_{27}H_{44}O$. B. showed the alc. nature of the O by prepg. the acetate, propionate and benzoate. In addition to W., other chemists as Jaeger (*C. A.* 1, 3060) and Pickard and Yates (Philip, *C. A.* 2, 2487) have noted important differences in the behavior of sitosterol and cholesterol. Stigmasterol was first obtained by Windaus (*Ber.* 39, 4378) from so-called phytosterol of the calabar bean. Its m. p. (as obtained by H. and G., 170°) is considerably higher than that of sitosterol ($136-7^{\circ}$) and it differs also in compn., having the formula $C_{28}H_{48}O$ or $C_{28}H_{46}O$. It adds 2 mols. Br while sitosterol adds only 1 mol. With acid it enters into combination to yield esters. *Sitosteryl salicylate*, $HOC_6H_4CO_2C_{27}H_{46}$, by heating the well triturated components 4 hrs at $160-70^{\circ}$, gelatinous flakes from Et_2O + alc., gradually becoming cryst., m. 147° . *Phenylurethan*, $PhNHCO_2C_{27}H_{46}$, by heating the alc. with $PhNCO$ a few min. at 180° , crystals from Et_2O + pet. ether, m. 174° . Br in excess converts sitosterol at the ordinary temp. into the *bromides*, $C_{27}H_{44}Br_{10}O$, brown powder, m. about 185° , and $C_{27}H_{42}Br_8O$, yellow powder, m. about 120° . Cholestenone, first reported by Diels and Abderhalden (*Ber.* 37, 3099), was obtained in better yield by Windaus (*Ber.* 39, 1518) by oxidizing the Br addition-product of cholesterol with $KMnO_4$ in H_2SO_4 and reducing the resulting ketodibromide with Zn and AcOH to the corresponding ketone. Similar treatment of sitosterol lead to the formation of *sitostenone*, $C_{27}H_{44}O$, crystals from MeOH, m. 82° . *Semicarbazone*, $C_{28}H_{47}ON_3$, crystals sintering 243° , m. 254° (decompn.). The following derivs. of stigmasterol were prepd.: *Palmitate*, $C_{16}H_{32}CO_2C_{28}H_{48}$, crystals of intense silky luster, m. 99° . *Stearate*, silky crystals, m. 101° . *Oleate*, crystals, m. 44° . *Salicylate*, needles, m. 175° . *Cinnamate*, crystals, m. 155° . *Tetrabromide*, $C_{28}H_{46}OBr_4$, by treating the sterol in Et_2O with Br in AcOH, crystals, m. 205° (decompn.).

W. O. E.

The action of alkali and alkaline earth cyanides on sugars. II. E. RUPP AND A. HOGLZLE. Univ. Koenigsberg. *Arch. Pharm.* 253, 404-15(1915).—The exptl. clarification of the interaction between dextrose and K and Ba cyanide solns. resulted in developing a simple method for the prepn. of α -glucoheptonic acid (cf. *C. A.* 8, 1356). Further work along this line has shown that a diminution in the OH ion concn. or decrease in the hydrolysis of KCN brings about a smoother reaction. Thus, a concd. soln. of Zn K cyanide likewise develops with grape sugar copious quantities of NH_3 , the reacting mixt. remaining practically colorless over the space of a week. Pure $Zn(CN)_2$, however, on account of its insoly., shows no tendency to react with dextrose. Heretofore, only the easily sol. Ba salt of α -glucoheptonic acid, $(C_7H_{13}O_6)_2Ba$, was known, hence the opportunity was taken to prep. the difficultly sol. *basic barium salt*, $CH_2OH(CHOH)_4CO_2BaOH$, in the form of warty crystals. In studying the velocity of action and expenditure of CN in solns. containing dextrose and KCN, the observation, interesting both from a chem. and forensic standpoint, was made that weak acid solns. containing dextrose and HCN suffer no greater decrease in cyanogen even after the lapse of weeks than those containing a minimum of alkali within an hour's time. It may be readily understood from the above that HCN in cadavers often disappears with great rapidity down to the merest traces, while, on the other hand, cases are known where the poison could be easily detected after the lapse of weeks and even months. The behavior of mannose towards KCN and $Ba(CN)_2$ is very like that recorded for dextrose (cf. *C. A.* 8, 1356). By means of this reaction the prepn. of mannosecarboxylic acid becomes an easy matter. In the case of levulose, KCN and $Ba(CN)_2$ at first cause liberation of HCN (indicated by a strong odor) which after several hrs is followed by a distinct NH_3 odor. The ketohexose differs in this respect from the aldohexoses, dextrose and mannose, which immediately develop NH_3 . The behavior

of galactose, lactose and maltose, towards the above cyanides was not essentially different from that noted for levulose.

W. O. E.

Some points connected with the representation of the benzene formula. GARRAISE LEBAS. London. *Chem. News* 113, 73-4(1916).—A new formula (I) for

(I)

(II)

C_6H_6 , proposed in a previous article, is discussed in its relations to the centric (Armstrong) and the Kekulé formulas. In combination with the centric, it gives a formula (II) which expresses more than either, and suggests the possibility of the Kekulé formula. But (II) is incomplete; it must be made to express the hypothesis of a difference between the valences of different atoms. The centric formula supposes the forces to be directed inward. They should be represented as directed alternately inward and outward. On this assumption the combination formula can also be modified (III). With the additional assumption of vibrating valences, the centric formula

(III)

(IV)

(V) can be regarded as a phase of the vibration of 2 extreme phases, represented by

(V)

(VI)

alternate Kekulé formulas (IV and VI). (III) involves all three. From a static viewpoint it resembles the field of force shown by 6 magnetic poles arranged in a ring, alternately + and —, the forces directed outwardly from the + poles and inwardly from the — poles. Dynamically, the diagram shows the disposition of the free valences at different phases of the vibration. The possibility of interaction between the valences in the *p*-position, causing the centrally directed valences to resemble those in the diagonal formula of Claus, can be represented by completing the diagonals by dotted lines. (III), though incomplete, is more nearly complete than any other one, and is probably best worth preserving, together with (IV), (V) and (VI). J. F. SMITH.

Glutaconic acid. I. P. E. VERKADÉ. *Proc. Acad. Wetenschappen* 18, 981-92 (1915).—Thorpe (*J. Chem. Soc.* 87, 1669 (1905); *C. A.* 6, 1150-1, 3408-9; 7, 336-7, 1710; 8, 69, 325, 1747) has given a survey of the peculiar structure and isomerism phenomena of the alkyl and aryl derivs. of glutaconic acid and their anhydrides, dicarboxylic esters, etc. With this paper begins the publication of some physico-chem. confirmations of some of the peculiarities of these acids. T. showed that in the glutaconic acid mol., $CO_2H.CH_2.CH:CH.CO_2H$, the α and γ positions

are identical. A true methylene group ($>CH_2-$) is not present in these acids; one of the H atoms is mobile between the α and γ C-atoms: The double bond is "floating." If an acid of the "mobile" class is dehydrated under certain conditions, a hydroxyanhydride is formed, from which, on rehydration, the normal acid is regenerated:

Hence, the normal acid is preceded by a *labile* acid. In some cases the labile acid has been isolated. The labile acid has a double bond, and should show *cis* and *trans* isomerism. This is indeed the case with β -phenyl- α -glutaconic acid (C. A. 8, 69), so that 3 isomers of this acid are known, which powerfully supports T.'s conceptions. The other labile acids are known in only one form, probably the *cis* form. As to the relation of glutaconic acid to this theory: (1) It may be obtained by several different methods: (A) Conrad and Guthzeit (*Ann.* 222, 253(1883); *Ber.* 15, 2841(1882)), m. 130-4°. (B) Pechmann-Blaise (*Ann.* 261, 157(1891); *Ber.* 24, 3250(1891); *Bull. soc. chim.* [3] 29, 1013(1903)). (C) Morgenstern and Zerner (*Sitz. Akad. Wiss., Wien* 119, 589(1910)), m. 129-9.5°. (D) von Pechmann (*Ann.* 264, 301(1891)), m. 132-4°. (E) Büchner (*Ber.* 23, 703(1890); *Ann.* 273, 238(1893)), m. 127-8°. If the identity of these forms were established, one form would appear which was formed under all conditions and must be the most stable. Such differences in stability of *cis* and *trans* isomers are not otherwise known. Further, Perkin and Tattersall (*J. Chem. Soc.* 87, 361(1905)) failed in every attempt to produce an isomer of glutaconic acid. (2) Thorpe's sym. formula is supported by the fact that the known glutaconic acid does not possess all the properties of either the *cis* or *trans* form. (3) For an acid with a floating double bond the reduction velocity should differ from that of an acid with an ordinary double bond. Measurements with glutaconic and aconitic acids (C. A. 7, 591) do in fact show such differences. (4) T. (C. A. 6, 3408) obtained from glutaconic acid a hydroxyanhydride, $\text{CH}:\text{CH}.\text{CO}.\text{O}.\text{C}(\text{OH}):\text{CH}$, which on hydration under

different conditions yields the same acid (m. 137°). Therefore the intermediate labile acid is very unstable. To prove the existence of the labile acids by a physico-chem. process, the hydration of the hydroxyanhydride was observed under various conditions at different temps. *Prepn. of glutaconic acid by different methods*: (A) gave most rapid results, but only a 20% yield, m. 136-8°, without decompn. (B) gave excellent results. The yields are those stated by Blaise; m. p. as in (A). (C) gives glutaconic acid as a secondary product (Fichter and Dreyfus, *Ber.* 33, 1452(1900)); m. p. 135-7°. For the prepn. of large quantities this is the best method; it is cheap and gives relatively high yields. (D) gave an 18% yield, m. 135-7°. (E) (linking $\text{N}_2\text{CH}_2\text{CO}_2\text{Et}$ with $\text{CH}_2:\text{CH}.\text{CO}_2\text{Me}$) yielded (a) *trans*-trimethylene-1,2-dicarboxylic, (b) glutaconic, and (c) *cis*-trimethylene-1,2-dicarboxylic acids. In contrast with (a) and (c), (b) instantly reduces alk. KMnO_4 ; it m. 136-8°. The glutaconic acids obtained by methods (A) to (E) were identical in all respects. This identity is confirmed by the results to be discussed in the communication to follow. In no case could the presence of an isomeric glutaconic acid be detected. *Properties of glutaconic acid*: No anhydride is formed by keeping for months *in vacuo* over P_2O_5 . On evapn. of an aq. soln., a little β -hydroxyglutaric acid is formed, and some resinification occurs. No color is obtained with FeCl_3 in EtOH, but in aq. soln. a brownish red color occurs. No $\text{Fe}(\text{OH})_3$ is deposited on boiling. *Attempt to find a new synthesis of glutaconic acid*: Thorpe and Rogerson (*J. Chem. Soc.* 87, 1685(1905)) obtained β -alkylglutaconic acids by condensation of $\text{NCCHNaCO}_2\text{Et}$ with $\text{AcCH}_2\text{CO}_2\text{Et}$ or its alkyl derivs. $\text{C}_6\text{H}_5\text{N}$ derivs. were often formed also. A similar condensation was tried with $\text{HCOCHNaCO}_2\text{Et}$ and $\text{NCCH}_2\text{CO}_2\text{Et}$ in the hope of obtaining ethyl α -cyanoglutaconate. To a soln. of 60 g. of $\text{HCOCHNaCO}_2\text{Et}$ in 150 cc. of abs. EtOH were added 45 g. of $\text{NCCH}_2\text{CO}_2\text{Et}$ and the whole heated on a H_2O bath 0.5 hr. (until decompn. set in). The yellow gelatinous mixt. was taken up in dil. HCl and shaken with Et_2O , washed with dil. NaOH and H_2O , and the Et_2O

evapd., leaving 30–35 g. of a pale yellow, very thick viscid oil. This ester completely resembled the α -cyanoglutaconic ester obtained by Guthzeit and Eyssen (*C. A.* 4, 901) from isoimidodicarboxylglutaconic ester, and the same ester prepd. with aq. NaOH. It had a bitter taste, gave a carmine color with alc. FeCl_3 , and could not be distd. under any circumstances. Guthzeit and Eyssen could not isolate any hydrolysis product after sapon. with acids or alkalis. In this research tests were made, after sapon. with dil. KOH, KOMe, 10% HCl, concd. H_2SO_4 , and 30% H_2O_2 + KOH, for the presence of glutaconic, malonic and 2,6-dihydroxypyridine-5-carboxylic acids, and for Et 2,6-dihydroxypyridine-5-carboxylate and 2,6-dihydroxypyridine, all of which might be expected. The result was always negative. The acid thus prepd. must then have another structure. An isoimido structure, $\text{EtO}_2\text{CC}:\text{CH}:\text{CH}:\text{C}(\text{OEt})\text{O}:\text{C}:\text{NH}$, is supported by the fact that NH_3 splits off in all

the sapon. methods tried, and by the carmine color shown by all sapon. products when exposed to air, probably indicating the presence of 6-ethoxy- α -pyrone derivs. An effort to condense $\text{HCOCHNaCO}_2\text{Et}$ and malonic ester to isoaconitic ester failed; a simple double decompn. took place, yielding sodiomalonic and free formylacetic esters.

J. F. SMITH.

The composition of the hydrochlorides obtained from formaldoxime. C. H. SLURRGA. *Proc. Akad. Wetenschappen* 18, 1007–12 (1915).—According to Schöll (*Ber.* 24, 579 (1891)), the hydrochloride obtained from formaldoxime has a variable compn. owing to a progressive change during its formation. Dunstan and Bossi declare that it consists of 3 mols. of oxime to 1 mol. of HCl. A study of these contradictory results showed that the primarily formed salt loses HCl readily until it contains 2 mols. of oxime to 1 mol. of HCl; the primary product (recrystd. once from MeOH and then from Et_2O , and freed from Et_2O at 60° by a current of dry air containing HCl), contained 1 mol. of oxime to 1 mol. of HCl. After 2 hrs. *in vacuo* over H_2SO_4 it contained 2 mols. of oxime to 1 mol. of HCl. After repeated recrystns. and drying for weeks *in vacuo* over KOH it contained approx. 3 mols. of oxime to 1 mol. of HCl. The colorless oil from which the primary product crystd., freed from Et_2O by dry air at 60° and dried for weeks *in vacuo* over H_2SO_4 , contained approx. 2 mols. of oxime to 1 mol. of HCl. On distn. under 1 atm. it decompd. at about 110° , as did the solid salts at 130° , with violent evolution of HCl. These results seem to support Schöll's belief that the free acid causes a change in the salt mols. The nature of this change is studied by observing the basicity of the bases of the three salts. For this purpose the velocity consts. (k') of their catalytic influence on the sapon. of EtOAc, and on the inversion of sucrose at 25° , were compared with those of equiv. amts. of HCl (k). The catalytic influence of the neutral oxime salt mols. was compensated in the free acid by the addition of amts. of NaCl corresponding with the nonhydrolyzed portion of the oxime salt. Putting degree of hydrolysis $x = k'/k$, the dissociation const. of the base $k_b = K_w (1 - x)/(N - x^2)$, where k is the ion product of H_2O (1.1×10^{-14} at 25°) and N is the normality of the soln. The salt with 1 mol. of oxime gave values of approx. 24 for the const. $k_b \times 10^{-13}$. The salt with 3 mols. of oxime gave values of approx. 3; for the salt with 2 mols. of oxime, x becomes nearly = 1; k_b is much smaller than for the other two salts. The inversion measurements agreed satisfactorily with those of sapon. These values of k_b indicate that the basicity of the solid salt decreases with decreasing HCl content, and hence that the HCl causes a shifting of atoms which lessens the basicity. This may be due to formamide formation, but is better explained by assuming a cyclic arrangement of 3 oxime mols.; the base of the primarily formed salt then would be:

Of this base 1 mol. can combine with 3 mols. of HCl; its dissociation const. is about $k_b = 23 \times 10^{-12}$. If now a Beckmann rearrangement sets in, the base of the secondarily formed salt would be:

One mol. of this base can combine with only 1 mol. of HCl; its dissociation const. is only $k_b = 3 \times 10^{-12}$. The base of the liquid salt is still weaker. The rearrangement here seems to have passed through the 2nd phase, forming the $>\text{C:O}$ group, and breaking up the cycle. How can (I) and (II) explain the decompn. studied by Dunstan and Bossi? The salt $(\text{CH}_2\text{:NOH})_3\text{HCl}$, heated some hrs. in a sealed tube at 120° in H_2O with an excess of HCl, yielded 2 mixts.: $\text{NH}_2\text{OH} + \text{CH}_2\text{O}$ and $\text{NH}_3 + \text{CH}_2\text{O}$. The higher the HCl concn., the more of the first was formed. An excess of H^+ ion would shift the equil. between the trimol. bases in the direction of (I), which must, according to the structure, yield NH_2OH and CH_2O . The weaker base (II) yields NH_3 and CH_2O . The reduction of the salt $(\text{CH}_2\text{:NOH})_3\text{HCl}$, converting all the N to NH , agrees with the structure of (II), since $-\text{OH}$ attached to N is more readily reduced than when attached to C. A more extended article in *Rec. trav. chim.* will explain the subject further.

J. F. SMITH.

Action of sodium and alkyl halides on aldehydes, ketones, etc. NAGAYOSHI NAGAI, AKIRA OGATA AND KAMETARO TAKATA. *J. Pharm. Soc. Japan* 1916, No. 407, 3-21; cf. Schorigin, *C. A.* 2, 3353.—The reaction on ketones runs smoothly with the formation of approx. 60% of the theoretical amt. of tertiary alc. Camphor forms a compd. of the same chem. compn. as methylborneol but with a lower m. p. ($135-46^\circ$) (cf. Zelinski, *Ber.* 34, 2883). Methylmenthol, m. $105-6^\circ$, and $\text{PhCH}_2\text{CMe}_2\text{OH}$, m. $88-93^\circ$, were prepd. from menthone and PhCH_2Ac , resp. With aldehydes the reaction proceeds less smoothly. Na, EtI and BzH yielded only 31% PhCHEtOH ; piperonal, etc., only 7% piperonaethylcarbinol. PhBr, BzH and Na yielded 46% PhCOH ; BzCl, EtI and Na 40% PhCOEt . On passing a current of CO_2 into PhBr and Na in Et_2O , 7.5% BzOH was formed. An abstr. in German precedes the article.

H. W. DAUDT.

Tetrahydroxybiphenyl from resorcinol melt. OSCAR V. FRIEDRICH. *Arch. Kemi. Min. Geol.* 6, No. 19, 1-20(1915).—As the temp. of fusion of resorcinol with NaOH is increased more biresorcinol and less phloroglucinol is formed. By methylating biresorcinol in Et_2O with CH_3N_3 , biresorcinol di-Me ether, $\text{C}_{12}\text{H}_6(\text{OH})_2(\text{OCH}_3)_2$, m. 76° , is prepd. Crystals from H_2O contain 1.5 mols. H_2O and m. 67° . MeI and Me_2SO_4 yield the tetra-Me ether, m. 108° . Attempts at oxidation of the di-Me ether with KMnO_4 and CrO_3 with a view to forming $(\text{HO})_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ were unsuccessful. Treatment of biresorcinol with fuming HNO_3 resulted in the formation of $(\text{CO}_2\text{H})_2$ and a red NO_2 compd., probably hexanitrobiresorcinol, which is very sol. in Et_2O and explodes at about 230° . Benedick and Julius (*Monatsh.* 5(1884)) prepd. the pure compd. by titration of the Ac deriv. It behaves like an acid, decomp. carbonates with formation of orange-yellow salts. The H_2O soln. is colored deep red by FeCl_3 . It cannot be methylated with Me_2SO_4 . On reduction with Sn and HCl it yields hexaaminobiresorcinol hydrochloride, $\text{C}_{12}(\text{NH}_2)_6(\text{OH})_4\cdot 4\text{HCl}$, colorless, decomp. $180-90^\circ$, very sol. in H_2O , difficultly sol. in alc. The H_2O soln. turns red on heating or on exposure to air. FeCl_3 forms a carmine-red color. The free base could not be isolated on account of its in-

stability in soln. The salt reduces AgNO_3 . Hexanitrobiresorcinol tetra-Me ether is formed by methylating the hexa- NO_2 compd. with CH_3N_3 , yellow needles from alc., m. 208° , sol. in C_6H_6 and Et_2O . Nitration of tetra-Me ether with fuming HNO_3 yields tetranitrobiresorcinol tetra-Me ether, yellow needles from acetone, sol. in AcOEt , no definite m. p., begins to discolor and decomp. at about 220° . When Cl is passed into bireisorcinol in ice-cold AcOH hexachlorobiresorcinol, m. 283° , is formed; rosettes from alc. If the above soln. is not cooled a more energetic reaction takes place with the formation of the decachloro compd., white needles from AcOH , m. $170-7^\circ$. Hexachlorobiresorcinol forms a tetra-Ac compd., with Ac_2O and anhydrous AcONa , needles, m. 229° . With CH_3N_3 the di-Me ether, m. 180° , is formed; with Me_3SO_4 the tetra-Me ether, which crysts. from AcOH , sinters 185° , m. 220° . Hexabromobiresorcinol was prepd. by adding Br to bireisorcinol in AcOH until the color remained permanent (cf. Meyer and Desamari, *C. A.* 3, 2696), crystals from alc.; begin to decomp. 180° but do not m. 320° . The di-Me ether, m. $194-6^\circ$, is prepd. by methylating hexabromobiresorcinol with CH_3N_3 ; the tetra-Me ether, m. 211° , with Me_3SO_4 . Br with bireisorcinol tetra-Et ether forms hexabromobiresorcinol tetra-Et ether, needles from C_6H_6 , m. 288° . In German.

H. W. DAUDT.

Stereochemical investigations. BROR HOLMBERG. *Arkiv. Kemi. Min. Geol.* 6, No. 1, 1-20(1915); cf. E. Biilmann, *Ann.* 339, 351(1905).—Inactive, *l*- and *d*-thiomalic acids were prepd. from the corresponding xanthogensuccinic acids and NH_3 . *i*-Acid, m. $149-50^\circ$. *l*-Acid, m. $152-3^\circ$. For solns. of 1 g. in 20 cc., $[\alpha]_D^{17}$ in acetone -75.8° , in AcOEt -76.5° , in abs. alc. -64.8° , in H_2O 46.7° . *d*-Acid, m. $152-3^\circ$; $[\alpha]_D^{17}$, as above, in acetone 76.1° , in AcOEt 76.5° , in abs. alc. 64.4° . No noticeable conversion of the *l*-acid to the *d*-acid is caused by heating for 6 hrs. on the water bath with 1 *N* H_2SO_4 , 0.25 *N* KOH or 0.25 *N* KSH . When a 0.25 mol. soln. is heated alone a change of 7% takes place and when between 0.25 and 0.75 mol. KOH per equiv. acid is added the change is as high as 60%. KSH with *l*-bromosuccinic acid forms either *d*- or *l*-thiomalic acid depending on the conditions of concn., etc. *l*-Disulfidosuccinic acid, prepd. by oxidation of *l*-thiomalic acid with air in the presence of FeCl_3 , m. $167-8^\circ$. For solns. of 0.5 g. in 10 cc., $[\alpha]_D^{17}$ in abs. alc. -272.9° , in acetone -269.3° , in H_2O 290.5° . *d*-Disulfidosuccinic acid, prepd. in like manner from *d*-thiomalic acid, m. $167-8^\circ$; $[\alpha]$ in abs. alc. 272.8° , in acetone 270.2° . The Ba salt is a white powder. *dl*-Disulfidosuccinic acid was prepd. by mixture of the *l*- and *d*-acids in equal quantity. *i*-Thiomalic on oxidation yields a mixture of *dl*- and mesodisulfidosuccinic acids, which are difficult to sep. An abstr. in German follows the article.

H. W. DAUDT.

The preparation of absolute alcohol. L. W. WINKLER. *Z. angew. Chem.* 29, I, 18(1916).—In order to prep. 100%, NH_3 -free EtOH , 99% EtOH is distd. with Ca filings which are prepd. as follows: First the filings are well sieved to remove most of the Ca nitride. They are then shaken in a flask with CCl_4 and collected on a filter, after which another washing with CCl_4 suffices to remove all the petroleum and most of the remaining nitride. After drying the filings in an atm. of CO_2 until the odor of the CCl_4 is no longer perceptible, they are ready for use. Twenty grams of filings are used for every l. of EtOH to be distd. In order completely to remove the NH_3 from the anhydrous distillate, a few cg. of alizarin are dissolved in a l., and 0.5 g. of dried tartaric acid is dissolved in another 10 cc. The alc. tartaric acid soln. is carefully added to the anhydrous distillate containing the alizarin until the reddish blue color of the latter turns to a clear yellow. After adding a few more drops of the alc. tartaric acid soln. the neutralized soln. is distd. again with precautions to exclude atm. moisture.

E. A. TSCHUDY.

Nitrosohydrazones and their rearrangement. M. BUSCH AND HERM. KUNDER. Univ. Erlangen. *Ber.* 49, 317-34(1916); cf. *C. A.* 10, 328.—B. and K. believe their

work shows beyond doubt that nitrosohydrazones have the nitrosoamine structure, $RN(NO)N:CHR$, and are not C-nitroso compds. $RNHN:C(NO)R$ (Bamberger and Pemsel, *Ber.* 36, 359 (1903)). When $PhNHN:CHPh$ in 20 parts cold $AcOH$ and a little alc. is treated slowly with excess of $NaNO_2$ and then with H_2O , a yellow to brown-yellow viscous oil, $PhN(NO)N:CHPh$, is obtained; it gives the Liebermann reaction, dissolves in concd. H_2SO_4 with blue color and reforms the hydrazone with Zn dust and $AcOH$; if allowed to stand in Et_2O some time, it deposits yellow needles, m. 189° , of $(PhCH:NNPh)_2$, and the filtrate, allowed to stand 1-2 days more and concd., yields red crystals, m. $101-2^\circ$, of $PhNHN:C(NO_2)Ph$; under the influence of ethylates, it rearranges into $PhN:NC(:NOH)Ph$. $PhNMeN:CHPh$, on the other hand, is unchanged by HNO_2 under the above conditions, even after several hrs. *Benzal p-bromophenylnitrosohydrazone*, yellow needles, m. $68-9^\circ$ (foaming), gives the Liebermann reaction, dissolves in H_2SO_4 with green color, yields on standing in C_6H_6 red needles probably consisting of the compd. $BrC_6H_4NHN:C(NO_2)Ph$, while from the Et_2O soln. after standing some time petr. ether ppts. yellow crystals m. 85° , at once resolidify to a blood-red mass and m. again 120° ; not enough was obtained for further study; it may be an isomer of the NO compd. *Benzophenone phenylnitrosohydrazone*, $PhN(NO)N:CPh_2$, obtained almost quant. from 20 g. $PhNHN:CPh_2$ in 250 cc. $AcOH$ slowly treated at $15-20^\circ$ with 10 g. $NaNO_2$ in concd. aq. soln., lemon-yellow crystals, stable for days in the air, decomp. quite rapidly in sealed vessels with evolution of nitrous fumes, seps. from Et_2O -petr. ether in lemon-yellow needles, from Me_2CO-H_2O in lemon-yellow columns, turns brown about 100° , m. 105° (foaming), gives the Liebermann reaction, dissolves in H_2SO_4 with blue to greenish blue color, regenerates the hydrazone with alc. KOH , with Zn dust in cold $AcOH$ or when boiled with C_6H_6 . When, however, the concd. C_6H_6 soln. is allowed to stand 2-3 days at room temp. and treated with petr. ether there is pptd. 70% of $p-O_2NC_6H_4NHN:CPh_2$, light yellow needles or leaflets, m. 154.5° . The same change is smoothly effected in 8-10 parts Et_2O and a few drops of $AcOH$; B. and K. believe that their compd. is identical with Bamberger's $PhN:NC(NO_2)Ph_2$ and that possibly in his synthesis of his compd. from PhN_2X and $PhCH_2NO_2$ (*Ber.* 33, 2055 (1900)), the nitrohydrazone was formed by rearrangement during the purification of the crude product with boiling alc. If HCl gas is passed through the Et_2O soln. of the NO compd. until it just assumes a reddish tinge or it is treated with a little alc. HCl and allowed to stand 15-20 hrs., $o-O_2NC_6H_4NHN:CPh_2$, red needles or prisms from Me_2CO , m. 165° , is formed in addition to the p -compd., from which it is sepd. by means of cold alc. KOH , the o -compd. being almost insol. in this reagent. The p - and o -compds. are also obtained, in 10 and 3.5 g. yield, resp., from 20 g. $PhNHN:CPh_2$ in 350 cc. Et_2O allowed to stand 24 hrs. with 3 cc. N_2O_4 . In alc. the rearrangement of the NO compd. gives, besides the above o - and p - NO_2 compds., 2,4- $(O_2N)_2C_6H_2NHN:CPh_2$, orange-red prisms, m. 231° , also obtained from $PhNHN:CPh_2$ and N_2O_4 when the Et_2O is distd. off before removing the excess of N_2O_4 , when the NO compd. is allowed to rearrange in C_6H_6 in the presence of $AmNO_2$ or when the o - or p - NO_2 compd. in Me_2CO is allowed to stand 10-15 min. with a few drops of concd. HNO_3 . The p - NO_2 compd. with Zn dust and $AcOH$ not much above 20° gives *benzophenone p-aminophenylhydrazone*, faintly yellowish leaflets from C_6H_6 -petr. ether, m. $166-7^\circ$; *hydrochloride*, gray leaflets from alc.- Et_2O , m. $215-6^\circ$, decompd. by boiling H_2O ; *chloroplatinate*, light leather-yellow needles; *acetyl derivative*, brownish needles from C_6H_6 -petr. ether, m. 204° . Diazotization in HCl gives a greenish yellow soln. depositing after a time, especially on warming, dark brown amorphous products, with evolution of N ; coupling with α - $C_{10}H_7NH_2$ yields the dye $Ph_2C:NNHC_6H_4N:-NC_{10}H_7NH_2$, difficultly sol. in boiling alc. with yellow-red color and sepg. in black-brown druses with greenish reflex, rubs to a dark red-brown powder, m. 203° , sol. in

H_2SO_4 with violet-blue color changing to crimson on diln. with H_2O . With BzH the hydrazone gives the *benzal compound*, $\text{Ph}_2\text{C}:\text{NNHC}_6\text{H}_4\text{N}:\text{CHPh}$, pointed needles from alc., m. $138-9^\circ$, hydrolyzed by boiling dil. H_2SO_4 ; with PhNCS in boiling alc. is obtained the *thiourea*, $\text{Ph}_2\text{C}:\text{NNHC}_6\text{H}_4\text{NHC(S)NPh}$, leaflets, m. 180.5° . *Acetophenone phenylnitrosohydrazone*, yellowish needles from Me_2CO , H_2O or C_6H_6 -petr. ether, m. about 82° (decompn.), quite unstable; its solns. evolve nitrous gases on gentle warming; in the air it quickly becomes yellow-green to green, the original color being restored in an NH_3 atm.; in concd. H_2SO_4 it dissolves with pure blue color immediately changing to violet-blue; the Liebermann test gives a beautiful blue color; NaOEt or Zn-AcOH regenerates the hydrazone; the C_6H_6 soln. on standing deposits $p\text{-O}_2\text{NC}_6\text{H}_4\text{-NHN}:\text{CMePh}$, brown- to orange-yellow needles from C_6H_6 -petr. ether, m. $182-3^\circ$. *o*-Substituents in ketone arylhydrazones seem at times to render the formation of NO compds. more difficult but in no case to prevent it. *Acetophenone pseudocumylhydrazone*, needles from alc., m. $140-1^\circ$, treated in the usual way with HNO_3 , gives the *nitroso compound*, unstable felted needles, gives the Liebermann reaction; with proper precautions it can be crystd. from C_6H_6 -petr. ether in yellowish, silky, felted needles, turns brown 50° , m. about 70° (decompn.), but decomps. so quickly, finally yielding a dark brown oil, that it could not be analyzed. *Acetophenone o-iodophenylhydrazone*, prisms from $\text{EtOH-Et}_2\text{O}$, m. 87° ; *nitroso compound*, prepd. in a large vol. of glacial AcOH , yellow needles, turns brown 72° , m. 75° (decompn.), regenerates the hydrazone with Zn-AcOH . *Benzophenone o-anisylhydrazone*, prisms from alc., m. 101° ; *nitroso compound*, pptd. from AcOH by H_2O as a vivid yellow flocculent product quickly boiling up to a resin. *Benzophenone vic-m-xylylhydrazone*, very faintly yellow, silky, flat needles from alc., m. $111-2^\circ$; *nitroso compound*, brownish yellow resinous mass, sol. in H_2SO_4 with green-blue color quickly becoming dark. CHAS. A. ROULLIER.

o-Substituted xyllyltellurium compounds. KARL LEDERER. Brussels. *Ber.* 49, 334-44(1916); cf. *C. A.* 6, 3417.—When the Grignard reagent from 156 g. 2,5- $\text{Me}_2\text{-C}_6\text{H}_3\text{Br}$, 20.7 g. Mg and 500 cc. Et_2O is slowly treated with 60 g. TeBr_3 , boiled 3 hrs., decompd. with ice H_2O , the Et_2O soln. washed with H_2O , freed in CO_2 from Et_2O , $\text{C}_6\text{H}_5\text{Me}_2$ and unchanged $\text{Me}_2\text{C}_6\text{H}_3\text{Br}$, the residue heated 0.5 hr. in CO_2 at 280° with Cu powder and distd. under 34 mm. the greater part b. $260-75^\circ$ and solidifies in the receiver. Crystn. from MeOH or EtOH gives 36.6 g. of *di-p-xylyl telluride*, silky needles, m. 72° . The mother liquors, concd., freed from the remaining telluride with HgCl_2 and from the excess of HgCl_2 with NaOH , leave *di-p-xylyl* as an oil of pleasant odor (Jacobson, *Ber.* 14, 2112(1881), describes it as m. 125°). From 5 g. of the telluride treated in Et_2O with Cl is obtained 6 g. *di-p-xylyltellurium dichloride*, needles from $\text{CHCl}_3\text{-MeOH}$, m. $197-8^\circ$. *Dibromide*, yellow needles from $\text{CHCl}_3\text{-EtOH}$, m. $189-90^\circ$. *Diiodide*, deep red-brown needles with 1 mol. CHCl_3 from $\text{CHCl}_3\text{-alc.}$, without solvent of crystn. from $\text{C}_6\text{H}_6\text{-benzine}$, sinters 156° , m. $161-2^\circ$. *Oxide*, $(\text{Me}_2\text{C}_6\text{H}_3)_2\text{-TeO}$, quant. obtained from 5 g. of the dibromide heated 1 hr. on the H_2O bath with 16 g. NaOH in 100 cc. H_2O , microcryst. powder from C_6H_6 , sinters 223° , m. $225-6^\circ$, very difficultly sol. in H_2O , the soln. being only extremely faintly alk.; on cooling it seps. in needles which do not lose wt. at 150° , so that it apparently seps. as the oxide, not the dihydroxide. When 1.5 g. of the dichloride is boiled with 300 cc. H_2O for some time, the undissolved part dissolved in 150 cc. H_2O and the combined solns. concd. to 300 cc. and cooled, there seps. a cryst. powder, sinters 223° , m. 227° , with 9.18-9.50% Cl ; 1.5 g. of this product, boiled with 500 cc. H_2O , the residue dissolved in 200 cc. H_2O and the combined solns. concd. to 300 cc., yields a powder which sinters 208° , m. 210° , with 6.67-6.82% Cl . The basic chloride, $(\text{Me}_2\text{C}_6\text{H}_3)_2\text{Te(OH)Cl}$ (calcd. Cl , 9.09%) or its anhydride (Cl , 9.56%), is therefore further hydrolyzed. The dibromide behaves similarly; the product obtained by one recrystn. when treated in H_2O with

KI gives the *basic iodide* or its *anhydride* (found 41.18% C, 4.45% H, 25.47% I), red-brown powder, sinters 50°, m. about 70°. *Di-p-xylylmethyltelluronium iodide*, from 2 g. telluride allowed to stand 10 days with 5 g. MeI, sinters 134°, m. 137° (decompn.); *picrate*, needles from alc., scales from H₂O, sinters 166°, m. 170°. *Di-p-xylyl telluride-mercuric chloride double salt*, from the telluride in Et₂O and aq. HgCl₂ columns from alc., contracts 170°, m. 179–80°. *Mercuric bromide salt*, from the components in alc., broad needles from alc. or AcOH, contracts 165°, m. 169–70°. *Mercuric iodide salt*, golden yellow needles, sinters 164°, m. 166–7°. *Di-2,4-xylyl telluride*, yellowish oil, b₁₀ 202–3°, is obtained in 25 g. yield from 156 g. Me₃C₆H₃Br, 20.7 g. Mg and 60 g. TeBr₃, the crude product, b₁₀ 200–30°, being purified by conversion into the dibromide (57 g.), 40 g. of which is slowly added to 50.5 g. MeI, 8.8 Mg and 250 cc. Et₂O, boiled 0.5 hr., decompd. with ice H₂O, treated with dil. HCl and the Et₂O soln. washed, dried and distd. in CO₂. *Telluronium dichloride*, microscopic columns from CHCl₃-MeOH, sinters 185°, m. 187–8°. *Dibromide*, yellow, microscopic, prismatic columns from CHCl₃-alc., sinters 197°, m. 200–1°. *Diiodide*, ruby-red, 4-sided columns from C₆H₆-Et₂O, sinters 179°, m. 181–2°. *Oxide*, sinters 212°, m. 216–7°, very difficultly sol. in H₂O, the soln. being only very faintly alk. The dichloride recrystd. from H₂O gives needles, m. 239–40°, with 50.24% C, 4.61% H, 9.55% Cl, sol. in H₂O with acid reaction and sepg. on cooling as a gelatinous mass which, when air-dried, forms a powder, m. 229–30°, with 6.10% Cl, again forming an acid aq. soln. *Di-o-xylyl telluride-mercuric chloride double salt*, from the telluride in Et₂O and aq. HgCl₂, seps. as a waxy ppt. quickly becoming cryst., sinters 98°, m. 106°, with 11.22% Cl (calcd., 11.64%); from much alc. it seps. in crystals sintering 83°, m. 88°, with 12.76% Cl, and from AcOH in crystals sintering 98°, m. 110°, with 10.89% Cl. *Mercuric bromide salt*, warty forms from alc., quickly disintegrating to a light powder, sinters 95°, m. 99°. *Mercuric iodide salt*, yellow, microscopical, 4-sided plates from alc., sinters 102°, m. 107–8°.

CHAS. A. ROULLER.

Mesityltellurium compounds. KARL LEDERER. Brussels. *Ber.* 49, 345–9(1916); cf. preceding abstr.—*Dimesityl telluride*, obtained in 27.2 g. yield from 97.25 g. MeC₆H₃Br, 10.3 g. Mg (12 hrs. boiling is required completely to dissolve the Mg) and 30 g. TeBr₃ boiled 6 hrs., dild. with 100 cc. C₆H₆, decompd. with ice H₂O, the washed Et₂O soln. freed from Et₂O, C₆H₆, C₆H₅Me₃ and Me₂C₆H₃Br in CO₂, the residue heated 0.5 hr. in CO₂ at 275° with 15 g. Cu powder, distd. under 16 mm. and crystd. from alc., softens 123°, m. 129°. *Telluronium dichloride*, needles from benzine-alc., sinters 177°, m. 178–9°. *Dibromide*, yellow needles from CHCl₃-alc., m. 105–6° (decompn.). *Diiodide*, 4-sided, deep dark red, almost black columns from Et₂O, sinters 108°, m. 111°. *Oxide*, from the dibromide and NH₄OH on the H₂O bath (with NaOH the reaction is very slow), apparently monoclinic columns from benzine, sinters 202°, m. 204–5°, difficultly sol. in H₂O with neutral reaction. The dichloride recrystd. from H₂O gives a substance sintering 223°, m. 237°, yielding on recrystn. a powder m. about 220°, with 6.74% Cl. The product once crystd. gave with KI a yellow ppt. contracting 93°, m. 100°, with 43.03% C, 4.57% H (calcd. for the *basic iodide anhydride*, 43.15, 4.39%, resp.). From 2 g. of the telluride allowed to stand 4 weeks with 6 cc. MeI is obtained, together with much unchanged telluride, only a small amt. of substance containing I, scales, m. 168–9°; if the mixt. is gently boiled 2 days or heated 15 hrs. at 100°, there is no reaction. HgCl₂, HgBr₂, and HgI₂ do not combine with the telluride.

Preliminary communication on mixed lead tetraaryls. KARL LEDERER. Brussels. *Ber.* 49, 349–50(1916); cf. Grüttner, *C. A.* 9, 804.—*Lead diphenyl di-o-tolyl*, needles from alc., sinters 129°, m. 134–5°, is obtained by slowly treating the Grignard reagent from 5.6 g. o-BrC₆H₄Me and 0.8 g. Mg with 5 g. Ph₂PbI₂, heating 0.5 hr. on the H₂O

bath, adding 25 cc. PhMe, decomp. with cold dil. HCl, freeing the Et₂O-PhMe layer from most of the solvents by distn. and from the rest by steam distn. and recrystg. the residue.

CHAS. A. ROULLER.

Crystallized polysaccharides from glycogen. HANS PRINGSHEIM AND STEFANIE LICHTENSTEIN. Univ. Berlin. *Ber.* 49, 364-9(1916); cf. *C. A.* 9, 83.—A Merck glycogen, practically ash-free, was used; it still contained a little albumin which, however, sepd. in dark flocks on sterilizing the aq. solns., that remaining in soln. being removed by protein precipitants. The fermentation with the *Bacillus macerans* is much more difficult than in the case of starch. The degradation products are the same as with starch, the only difference, possibly, being that more β -hexaamylose, as compared with tetraamylose, is formed with glycogen. Two 17.5 g. portions of glycogen in 5% aq. soln. were sterilized and inoculated with a potato culture of the bacillus; after 2 days at 37° the first gas bubbles formed; the gas evolution then increased, so that flocks of protein in the soln. rose to the surface, this stage lasting about a week; the fermentation then decreased and after 4 weeks no more gas was formed. The filtered soln. was now pptd. with colloidal Fe(OH)₃ and the filtrate and washings evapd. to 10 cc. *in vacuo* at 50°; after 24 hrs. in the ice chest, the dextrin β , mixed with a little of the "sludge" (presumably octaamylose), crystd. out; after soln. in 40 cc. H₂O, filtration from the sludge after 24 hrs. and concn., 1.5 g. pure β -hexaamylose was obtained (C 43.55%, H 6.41%, $[\alpha]_D^{20}$ in H₂O 157.8°); it gave the dibromide, orange prisms, and the I compd., red-brown prisms. Treatment of the filtrate from the dextrin β with I-KI yielded the characteristic green needles with metallic luster of the dextrin α I compd. from which, by decompn. in H₂O with Ag₂CO₃, filtration, treatment with H₂S, evapn. of the filtrate to dryness *in vacuo*, heating to boiling with 10 cc. of 96% alc. and diln. with hot H₂O until dissolved, is obtained 0.5 g. of the tetraamylose (C 44.09%, H 6.46%, $[\alpha]_D^{20}$ in H₂O 138.5°), gives the Br compd., light yellow needles. That these products were not formed from the starch in the potato cultures was shown by subjecting 20 g. maltose inoculated with a similar culture to fermentation for several weeks at 37°; although the gas evolution was very slight, the characteristic odor (due to Me₂CO) of *B. macerans* fermentations was recognized. The products worked up as above showed no amylose by the I reaction; the formation of the osazone with Ph-NHNH₂ showed the presence of considerable maltose. This, like the earlier negative expts. with glucose, also meets the objection that the amylose might have been synthesized by the bacillus from lower sugars.

CHAS. A. ROULLER.

Action of methylal on tetrahydropapaverine. AMÉ PICTET AND TSAN Q. CHOU. Univ. Geneva. *Ber.* 49, 370-6(1916); cf. *C. A.* 8, 101.—In order to det. why the condensation of tetrahydropapaverine (a) with MeCH(OEt)₂ takes place between the N atom of the isoquinoline ring and the 6-C atom of the veratryl ring, while the condensation of the similarly constituted veratrylnorhydrohydrastinine with HCH(OMe)₂ takes place at the 2-C atom (*C. A.* 6, 484), 5 g. (a)-HCl in 20 cc. HCl (d. 1.06) on the H₂O bath was treated in the course of 1 hr. with 10 g. HCH(OMe)₂; on cooling was obtained 80-5% of the *hydrochloride*, needles from HCl, m. 213°, of *morcoralydine* (b), C₂₁H₂₈O₄N, leaflets from dil. alc., m. 157-8°, sol. in cold H₂SO₄ without color but turning brown-red on heating, slowly turns yellow in the air or in neutral aq. solns. of its salts. *Picrate*, yellow needles from alc., m. 138°, turns red in the air; *chloroplatinate*, orange-red prisms from alc., blackens on heating and m. about 231°; *mercuric chloride salt*, yellow ppt., m. 158°. The constitution of (b) is analogous to that of the compds. obtained with MeCH(OEt)₂, but it is formed in only 1 (not 2 stereoisomeric) form; attempts to resolve it into its optical components with *o*-bromocamphor-sulfonic acid failed. For its physiol. properties, cf. Mayor and Wiki, *Rev. méd. Suisse romande*, 35, 490(1915), and Aftandilian, *Diss. Geneva*, 1914. Oxidation gives exclu-

sively *m*-hemipinic acid. Heating 0.4 g. (b), 0.8 g. I and 15 cc. alc. 2 hrs. at 100° gives *dehydronorcoralydine iodide* (c), $C_{21}H_{20}O_4NI$, yellow needles from 40% AcOH, m. 252.5°; *nitrate*, from the iodide and $AgNO_3$, prisms from H_2O , m. 261°; *chloride*, from the iodide and $AgCl$ in boiling H_2O , needles, m. 220°; *picrate*, needles from dil. AcOH, m. 255°. Free *quaternary base*, from the chloride and Ag_2O in warm H_2O , amorphous substance from alc.- Et_2O , m. 175°. When the nitrate suspended in $CHCl_3$ or Me_2CO is shaken vigorously with a few drops of concd. KOH, the base seps. with the solvent; short yellow needles, m. 215°, from $CHCl_3$; dark yellow needles, m. 150°, from Me_2CO . The chloride or nitrate forms in 10% KOH a clear reddish soln., which on standing or short warming on the H_2O bath deposits a pulverulent, brown, basic substance (probably corresponding to dehydroberberine), m. about 195° (*hydrochloride*, yellow needles, m. 212°); the alk. filtrate remains clear and doubtless contains the salt (I) but addition of acid at once ppts. *ketodehydronorcoralydine* (II), yellow prisms from

C_6H_6 or xylene, m. 190°, insol. in H_2O , acids and alkalis, gives in H_2SO_4 with 1 drop HNO_3 an intense violet color. (c) boiled 1 day with $MeMgI$ in Et_2O and shaken with HCl gives the *hydrochloride*, m. 120°, of the base (III), yellow crystals from $MeOH$,

m. about 180°, which was obtained in such small amt. that its constitution was detd. merely by converting it with alc. I into dehydrocoralydine iodide, golden yellow needles, m. 263° (picrate, m. 243°).

CHAS. A. ROUILLER.

Introduction of acid radicals into the side benzene rings of anthracene. Preparation of 1-hydroxy-2-anthracoyl-*o*'-benzoic acid. ALFRED SCHAARSCHMIDT, partly with A. REH. Berlin. *Ber.* 49, 381-5(1916); cf. *C. A.* 9, 2255.—It was previously shown that in the introduction of acid residues into anthracene (a), *meso*-derivs. are always formed on account of the extraordinary reactivity of the H atoms of the middle ring. S. has now tried 2 ways of so lessening the reactivity of these atoms that acid radicals might be introduced into the side rings: (1) By reducing the (a) to the dihydro compd. and coupling it under very mild conditions with $BzCl$ in the presence of $AlCl_3$, but, probably with intermediate regeneration of (a), the Bz radical enters chiefly the *meso*-position. (2) By taking advantage of the orienting force of HO groups which, in general, is greater than the reactivity of *meso*-H atoms (cf. Bayer & Co., *C. A.* 6, 1536). As a matter of fact, when 45 g. $C_6H_5(CO)_2O$, 150 g. H_2BO_3 and 60 g. 1- $C_{14}H_9OH$ are ground to a uniform powder and quickly heated, the mixt. begins to become fluid at 195-200° and after short stirring at this temp. solidifies. After cooling, the brown-red mass is powdered and ground with H_2O , whereby it becomes brownish yellow; it is now boiled up with 4 l. H_2O , filtered, washed with hot H_2O , boiled up with 5 l. H_2O and 100 cc. concd. NH_4OH , filtered and cooled; during the filtration golden yellow crystals sep. on the filter and more are deposited from the filtrate. They consist of *ammonium 1-hydroxy-2-anthracoyl-*o*'-benzoate*, $HOC_{14}H_9COC_6H_4CO_2NH_4$. The crystals on the filter are purified by decantation with cold H_2O , combined with those sepg. from the filtrate, boiled with 7 l. H_2O and 25 g. soda, filtered hot and treated hot with dil. HCl . There is thus obtained 28 g. of the free acid (b), brownish yellow crystals from xylene, yellow needles from AcOH, m. 221°, sol. in H_2SO_4 with intense blue color soon changing to green; on pouring into H_2O the soln. deposits a brown-red ppt.

(see below). In attempting to prep. an acetate, it was found that a difficultly sol. red product was formed with AcOH , Ac_2O and NaOAc (but not without NaOAc) and, in pure cryst. form (brown-red leaflets, sinter 241° , m. 246°) with Ac_2O in xylene without NaOAc . It dissolves in H_2SO_4 with green color and is identical with the product obtained by allowing (b) to stand in H_2SO_4 , and, conversely, if H_2O is added to its H_2SO_4 soln., it gives (b). It is insol. in NaOH , even on addition of $\text{Na}_2\text{S}_2\text{O}_4$. S. assigns to it the *o*-quinone lactone structure $\text{O}:\text{C}_{14}\text{H}_9:\text{C}_6\text{H}_4.\text{CO.O}$.

CHAS. A. ROULLER.

Reduction products of 1- and 2-benzoylanthraquinones. ALFRED SCHAARSCHMIDT AND D. IRINGU. Berlin. *Ber.* 49, 386-96(1916); cf. *C. A.* 9, 2256.—In order to obtain further light on the deeply colored reduction products of 1-benzoylanthraquinones a general study has been made of the reduction products of the 1- and 2-Bz compds. in acid and in alk. soln. A new analysis of the blue compd. obtained in acid soln. from the 1-*p*- $\text{ClC}_6\text{H}_4\text{CO}$ deriv. (a) confirms the earlier results; attempts to split the product by heating with quinoline, KOH or 50% H_2SO_4 have thus far given no positive result, the products being non-homogeneous and showing so little tendency to cryst. that none has been isolated pure. 2-*p*-Toluylanthraquinone (b) treated in cold H_2SO_4 with the amt. of Al equiv. to 2 atoms H is practically not attacked; with the equiv. of 6 atoms H , the reduction product is for the most part sol. in alkalis with a red color which disappears on shaking with air, depositing a solid; attempts to recryst. the reduction product gave no satisfactory result, AcOH alone yielding a small amt. of a by-product, sinters 242° , m. 252° , with 82.01% C , 5.69-6.09% H ; the AcOH soln. was then boiled 1 hr. with Ac_2O and NaOAc , yielding light yellow felted needles, m. 154.5° , whose compn. (av. C 81.31%, H 5.25%) corresponds to that of a *toluylanthranyl*

acetate, $\text{C}_6\text{H}_5\text{CH}(\text{C}(\text{OAc}))\text{C}_6\text{H}_4\text{COC}_6\text{H}_4\text{Me}$. In NH_4OH with Zn dust, (a) is much more

difficultly reduced than (b); besides unchanged (a) is obtained a blue product of the same properties as that obtained in acid soln., but it is not homogeneous. (b) under these conditions yields an oily mass, evidently a mixt., insol. in alkalis and in alk. $\text{Na}_2\text{S}_2\text{O}_4$; repeated crystn. from AcOH finally yields a compd. m. $164-5^\circ$, having the compn. of *anthracyltolylcarbiny*l acetate, $\text{C}_{14}\text{H}_9(\text{MeC}_6\text{H}_4)\text{CHOAc}$ (C 84.71%, H 6.41%).

CHAS. A. ROULLER.

New heterocyclic systems. II. Pyrrolidine analogs, in which the nitrogen atom is replaced by phosphorus, arsenic or antimony. GERHARD GRÜTTNER AND ERICH KRAUSE. Charlottenburg. *Ber.* 49, 437-44(1916); cf. *C. A.* 9, 3247.—*Cyclo-tetramethylenephénylphosphine* (a), $\text{C}_6\text{H}_5\text{PPh}$, b_{16-8} $132-3^\circ$, d_4 1.0502, 1.0429, 1.0354, 1.0281, 1.0208 at 0° , 10° , 20° , 30° and 40° , n_D 1.5894 and $n_F - n_C$ 0.02163 at 22.5° , mol. wt. in freezing C_6H_6 162, is obtained in 7-8 g. yield from the Grignard reagent from 50 g. $(\text{CH}_3\text{CH}_2\text{Br})_3$ in 200 cc. Et_2O slowly treated with 25 g. PhPCl_2 in 3 vols. cold Et_2O , distd. in H under 20 mm. up to $340-50^\circ$ (bath temp.) and fractionated *in vacuo* in CO_2 up to 145° ; there remains a yellow viscous residue (see below) about equal in amt. to the phosphine. The latter is an oil of very strong characteristic phosphine odor, does not fume and oxidizes only slowly in the air at room temp., energetically reduces neutral and faintly acid (HNO_3) AgNO_3 . *Mercuric chloride compound*, $\text{C}_{10}\text{H}_{11}\text{PHgCl}_2$, from the components in C_6H_6 , strongly doubly refracting and dispersive rhombohedrons, m. $143-4^\circ$ (decompn.). Additive compds. are also obtained with CCl_4 , C_6Cl_6 , AsCl_3 , SbCl_3 , BiBr_3 , SiCl_4 , PhAsCl_2 , Ph_2AsCl , Et_3SiCl , SnBr_4 , Ph_2SnBr_2 . (a) reacts explosively with MeI at room temp., giving a non-crystallizable oil; with EtI after short warming on the H_2O bath is quant. obtained the *ethiodide*, white to pale

yellow cryst. powder from alc.-Et₂O, m. 122°; *propiodide*, microscopic tables, m. 153-4° on rapid heating, decomp. slightly below the m. p. on slow heating; *sec-propiodide*, pale yellow, apparently somewhat hygroscopic. Iso-AmI and (CH₃CH₂Br)₂ also yield yellowish oils after 2 hrs. warming. *Cyclotetramethylenephénylarsine*, in 17 g. yield from the Mg compd. from 70 g. (CH₃CH₂Br)₂ and 65 g. PhAsCl₂, b₁₅₋₆ 128.5°, mobile oil of faint, not unpleasant odor, does not markedly oxidize in the air at room temp., remains unchanged for months in the light, mol. wt. in freezing C₆H₆ 199-202, d₄ 1.2997, 1.2896, 1.2794, 1.2694, at 0°, 10°, 20° and 30°, n_D 1.6768 and n_F-n_C 0.0234 at 17° Satd. with Cl in CCl₄ it gives the *dichloride*, prisms, m. 120.5°, very hygroscopic, easily sol. in H₂O and alc. with decompn. *Mercuric chloride compound*, from the components in Et₂O, 6-sided leaflets from CHCl₃, m. 160-2°. *Methiodide*, white or very pale yellow cryst. powder from alc.-Et₂O, m. 135-6°; *ethiodide*, pale yellow cryst. powder, m. 85-6°; *propiodide*, needles from PrI, m. 123-4°; *sec-propiodide*, faintly yellowish cryst. powder, m. 113-4° (decompn.); *but-* and *isobutiodides*, oils. *Cyclotetramethylenephénylstibine*, in 15 g. yield from 50 g. (CH₃CH₂Br)₂ and 40 g. PhSbCl₂, oil of unpleasant odor rendered turbid by traces of O, b₁₀₋₁ 156-8°. *Dichloride*, doubly refracting rhombs from CCl₄, m. 150°; *diiodide*, doubly refractive needles from CCl₄, m. 149°. The high-boiling residue obtained in the prepn. of (a) is a viscous oil with the unpleasant odor of tertiary alkylarylphosphines and is permeated with solid particles; it energetically adds Br, alkyl iodides and HgCl₂, forming in the last case a cryst. product. The residues from the arsine and stibine showed similar properties. Mol. wt. detns. in C₆H₆ showed that they were substances of quite high mol. wts. C. A. ROULLER.

Addition of aliphatic nitro compounds to unsaturated compounds. E. P. KOHLER. *J. Am. Chem. Soc.* 38, 889-900(1916).—This work was undertaken for the purpose of prepg. cyclopropane derivs. with a NO₂ group combined with 1 of the ring C atoms by the following series of reactions: $\text{RCH:CHCOR}' + \text{MeNO}_2 \longrightarrow \text{RCH}(\text{CH}_2\text{NO}_2)\text{CHCOR}' + \text{Br}_2 \longrightarrow \text{RCH}(\text{CH}_2\text{NO}_2)\text{CHBrCOR}' \longrightarrow \text{RCH.CH}(\text{NO}_2)\text{CHCOR}'$.

The present paper deals only with the addition of nitroparaffins to PhCH:CHBr (a), but work now in progress shows that under proper conditions aliphatic NO₂ compds. combine quite generally with α,β-unsatd. ketones, many unsatd. esters, unsatd. nitriles and even unsatd. NO₂ compds. MeNO₂ itself does not combine with (a) either when the 2 substances are boiled alone or in ligroin, C₆H₆, alcs., etc.; if a little NHEt₃ or piperidine is added, the combination can be effected in any suitable solvent, but Na alcoholate is the most satisfactory condensing agent. A small amt. of alcoholate is sufficient to cause rapid disappearance of both ketone and NO₂ compd. but the resulting product is a mixt. of complex substances because the compd. formed from 1 mol. each of ketone and Na salt of the NO₂ compd. readily combines with more of the unsatd. ketone; it is therefore necessary to have an excess of NaCH₂NO₂ in soln. Thus, when 15 g. Na in 120 g. MeOH is added with const. shaking to 104 g. (a) and 37.5 g. MeNO₂ in 175 g. MeOH at about 40° as rapidly as possible without sepn. of solid Na compd., cooled, immediately acidified with glacial AcOH and finally cooled in a freezing mixt., there is obtained a max. yield of 92% (av. yield, 88.5%) of γ-nitro-β-phenylbutyrophene (b), needles from alc., m. 103°, does not reduce KMnO₄ in Me₂CO; semicarbazone, plates, m. 165°. (b) dissolves very sparingly in concd. aq. alkalis, more readily in alc. KOH, very easily in alcoholates; the solid sodium salt (c) may be obtained by adding Et₂O-ligroin to the concd. MeOH soln. of MeONa, MeNO₂ and (a), which gives a pale yellow cryst. ppt. containing MeOH; by satg. a cold soln. of MeONa in MeOH with (b) and allowing to evap. *in vacuo* over H₂SO₄, which again gives a product containing MeOH; or by heating (b) in C₆H₆ with the calcd. amt. of Na, which yields 90% of the Na salt as a white microcryst. powder. It dissolves readily

in cold H_2O without color and with very feebly alk. reaction, the soln. soon becoming milky and in about 1 hr. the (c) is completely hydrolyzed to NaOH and (b); the alc. solns. remain clear and colorless and on evapn. *in vacuo* deposit a cryst. Na compd. containing alc.; weak or strong acids, added to (c), or *vice versa*, quant. regenerate (b). Dry (c) slowly added to a little more than 1 equiv. of Br in cold CHCl_3 , poured into H_2O , freed from excess of Br with NaHSO_3 and from CHCl_3 *in vacuo*, yields 2 isomeric γ -bromo- γ -nitro- β -phenylbutyrophenones, sepd. by repeated crystn. from MeOH into needles, m. 90° , and thin plates or flat needles, m. 93° (a mixt. of the 2 begins to m. 70°). Both readily dissolve in NaOMe and these solns. rapidly react with Br to form the same γ , γ -dibromo compound, needles, m. $160-2^\circ$ (decompn.), more easily prepd. by dropping Br into cold solns. of (b) in NaOMe or of (a) and NaCH_2NO_2 in MeOH (yield, 80-5%); solns. in Me_2CO or alc. can be boiled a long time without appreciable change, but in the presence of an equiv. amt. of KI or KCN, 1 Br atom is replaced by H and, with excess of reducing agent, the 2nd more slowly but completely. When a concd. soln. of (b) in CHCl_3 is treated with a little Br, the reaction started by warming or adding a drop of Me_2CO , the soln. cooled and then treated with more Br until the color shows the presence of a slight excess, the product is γ -nitro- β -phenyl- α -bromobutyrophenone, needles from alc., m. 100° ; the mother liquors further yield small amts. of an isomer, thin plates from alc., m. 86° (yield of combined mono-Br derivs., 89%), and of a dibromo compound, prisms or thick needles, m. 105° (yield, 4%). Treated with slightly more than 1 equiv. KI in the least possible amt. of boiling MeOH, the mono-Br compds. give the α -iodo compound, pale yellow needles from alc., m. 123° . Heated with alcoholates, KOAc, KCN and other feebly alk. reagents, the α -Br compds. lose HBr and form a trimethylene deriv. (d), m. 93° . They cannot be further brominated but the γ -Br compd., by the same method used in prepg. the α -Br compd., gives the α , γ -dibromo compound, thin needles from alc., m. 130° ; in boiling alc. with KI it gives chiefly the α -I compd. while with Zn dust 1 of the products is (d); further bromination gives the α , γ , γ -tribromo compound, needles from CHCl_3 , m. 185° . γ -Nitro- β -phenylvalerophenone (e), from (a), NaOEt and EtNO_2 , is obtained quant. as a mixt. of stereoisomers, sepd. by repeated crystn. from Et_2O into very fine needles, m. 72° , and stout needles or plates, m. 100° ; the relative amts. of the isomers vary with the mode of acidification, strong acids and low temps. favoring the high-melting form; either form, converted into the Na salt and back into the ketone, again gives a mixt. of the 2, showing that they are the 2 racemic forms possible because the ketone contains 2 dissimilar asym. C atoms. γ -Bromo compounds, from the calcd. amt. of NaOMe allowed to stand 1 hr. with (a) and EtNO_2 in hot MeOH, cooled and treated with Br, fine needles from alc., m. 170° , and more sol. needles, m. 160° . The ketones in CHCl_3 readily react with Br but, probably owing to the number of stereoisomers formed, give no solid product, but the residue left after removing the solvent reacts with KOAc like the α -Br compds. and yields 2 solid trimethylene derivs. γ -Methyl- γ -nitro- β -phenylvalerophenone, m. 167° , is obtained in 92% yield from equiv. amts. of (a), Me_2CHNO_2 and 5 drops concd. NaOMe soln. in just enough MeOH to keep the ketone in soln. allowed to stand several weeks; it shows no tendency to form a Na salt, and while it easily dissolves in concd. alcoholates the process is accompanied by extensive decompn. and similarly Na in C_6H_6 slowly decomp. it. α -Bromo compounds, diamond-shaped plates, m. 165° , and stout prisms, m. 125° . The above facts, in combination with the observation that (a) and $\text{MeC}(\text{:NO}_2\text{Na})\text{CO}_2\text{Me}$ give a lactone, $\text{PhCH}_2\text{CH:CPh.O.CO.CMeNO}_2$, which with HCl yields a compd. identical with (e)

above, show that the addition of Na nitroparaffins to compds. containing the grouping C:C:C:O is the same as with Grignard reagents and other metallic derivs., the metal going to the O and the remainder of the mol. to the C atom in the 4-position. But,

unless the product is a tertiary NO_2 compd., it immediately rearranges into the NO_2 form.

CHAS. A. ROUILLER.

Catalyses with weak acids. IX. Rates of conversion of the stereoisomeric cinchona alkaloids into their toxines. H. C. BIDDLE. *J. Am. Chem. Soc.* 38, 901-8(1916), cf. *C. A.* 9, 2617.—It has been found (Massey, *Diss. Univ. Cal.*, unpublished) that the conversion of quinine and quinidine into quinotoxine follows the same laws as the corresponding conversion of cinchonine (*a*) and cinchonidine (*b*) into cinchotoxine (*c*), but that under like conditions the conversion rates of quinine and quinidine approach a common value. This raised the question whether the slightly different rates previously observed for (*a*) and (*b*) were real or only apparent; a reconsideration of these rates has shown that the speeds of change to a mean rotational value for the 2 alkaloids under like conditions approach identity within the limits of exptl. error, and furthermore that this mean rotational value probably represents the true rotation of the completely converted, *pure, non-racemized* (*c*). Slight variations in the rotatory value assigned to (*c*) will suffice to cause small, but appreciable, errors in the calcn. of the reaction rates; the detns. of the rotation of (*c*) by Roques (*Compt. rend.* 120, 1170 (1895)) and by B. shows that equiv. solns. of (*c*) are practically identical, irrespective of whether it is derived from (*a*) or from (*b*); they point to the apparent correctness of the hypothesis that the rotation of (*c*) should be the arithmetical mean of those of (*a*) and (*b*); and furthermore, they show that the rotation is not materially affected by considerable variations in the H ion concn. From the work of Hesse (*Ann.* 178, 262(1875)) and of R. it seemed that in the conversion of (*a*) and (*b*) into (*c*) a by-product was formed which imparted to the crude product a rotation lower than that of pure (*c*). Such a side reaction would lead to an apparent increase in the rate of conversion of (*a*) and a decrease in that of (*b*). To get a direct comparison with regard to the simultaneous conversion of the 2 alkaloids under the same conditions, equiv. mixts. of the 2 (each 0.05 *M*) in 1.7 *M* AcOH were heated at 99.4° ($\pm 0.2^\circ$) in sealed tubes exhausted to 20 mm.; the rotation in 0, 4, 6, 23, 25, 52, 111, 335 hrs. was found to be 3.21, 3.11, 3.00, 2.55, 2.55, 2.25, 1.75, 1.00° (Ventzke, for 1 dcm. at 18°), resp. There is thus a continuous fall although the conversion into (*c*) may be considered as complete before the end of 50 hrs. Assuming that the rotation of (*c*) is the arithmetical mean of those of (*a*) and (*b*), this continuous fall must be due to a secondary reaction (see below). Since in the 1st 6 hrs. the fall is only about 0.2° , the error due to this side reaction can be reduced to a minimum by studying the conversions of (*a*) and (*b*) during the early part of the reaction. This was done under exactly the same conditions as above (except that (*a*) and (*b*) were used singly instead of mixed together), and the mean values of K_1 and K_2 were found to be 0.0721 and 0.0734 for (*a*) and 0.0704 and 0.0704 for (*b*), the arithmetical mean of the initial readings of the 2 alkaloids being taken as the rotation of the corresponding (*c*) soln. Confirmatory evidence was obtained by detg. the (*c*) by extn. with Et_2O and resoln. in abs. Et_2O , in which both (*a*) and (*b*) are difficultly sol. The only reasonable explanation for the continuous fall in rotation (see above) is that the optically active compds. are slowly racemized during the protracted heating; this would account for R.'s supposed impurity, for the different rotations of (*c*) given in the literature and for the extraordinary care necessary to obtain a (*c*) of high rotation.

CHAS. A. ROUILLER.

Alkylcyanoacetic acids. JOHN C. HESSLER. *J. Am. Chem. Soc.* 38, 909-16(1916).— *α -Methyl- α -cyanopropionic acid*, obtained in 2.5 g. yield from 8.7 g. of the Et ester allowed to stand overnight in running H_2O with 9 g. KOH in 100 cc. MeOH, $b_D^{25} 132.5^\circ$, *m.* 57° ; *silver salt*; *barium salt*, prisms with 18 mols. H_2O . $\text{Et}_3\text{C}(\text{CN})\text{CO}_2\text{H}$, in 31% yield from 42.5 g. of the ester and 28 g. KOH in 300 cc. MeOH, *m.* 61° (Hesse, *Ann. Chem. J.* 18, 746(1896), gives 57°). *Salts*: *silver*, bulky ppt.; *barium*, needles; *lead*,

flat flakes; *calcium*, needles with 3 H₂O; *strontium*, prisms with 3 H₂O; *cadmium*, flat plates with 3 H₂O; *copper*, bright green rectangles with 3 H₂O. From 50 g. NCCH₂CO₂Et, in 100 cc. alc. and 10.2 g. Na in 250 cc. alc. treated with 80 g. PrI and allowed to stand overnight, is obtained 51.5 g. crude product (a), *b*₂₄ 117–30°; this is shaken in Et₂O with 10% NaOH and the alk. ext. acidified with dil. H₂SO₄ and extd. with Et₂O, giving 24.9 g. *α*-cyanovaleic acid; *silver* and *barium* salts; *ethyl ester*, from the Ag salt and EtI, *b*₇₁₈ 218–9°, *d*₂₅ 0.972. The Et₂O soln. of (a), after extn. with NaOH, yields 17.8 g. of *ethyl α-propyl-α-cyanovaleate*, *b*₂₂₋₃ 129–32°, *d*₂₅ 0.93; *free acid*, rhombic prisms, *m.* 41°, becoming syrupy over H₂SO₄ *in vacuo*; after 5 days it contained 1 mol. H₂O; *silver salt*, seps. with 1 H₂O. In the same way from 50 g. NCCH₂CO₂Et are obtained 20.5 g. *γ-methyl-α-cyanovaleic acid* (*silver salt*, powder; *barium salt*, needles with 2 H₂O; *ethyl ester*, *b*₇₁₈ 223–4°, *d*₂₅ 0.958), and 28.1 g. *ethyl γ-methyl-α-isobutyl-α-cyanovaleate*, *b*₇₁₈ 245–50°, *d*₂₅ 0.915 (*free acid*, *m.* 82°; *silver salt*, bulky ppt.). *Copper δ-methyl-α-cyanocaproate* (cf. C. A. 7, 3506), blue cryst. ppt. with 7 H₂O, turning green *in vacuo* over H₂SO₄; *barium salt*, needles with 2 H₂O; *chloride*, liquid; *anilide*, needles, *m.* 102°. *δ-Methyl-α-isoamyl-α-cyanocaproic acid*, from the ester and KOH in MeOH, needles from C₆H₆, *m.* 74–5°; *ammonium salt*, flakes, 2.9 g. of which dissolve in 100 cc. H₂O at 16°; *silver salt*, ppt.; *copper salt*, green flakes with 3 H₂O; *calcium salt*, rhomboids with 4 H₂O; *amide*, needles from alc., *m.* 152°. *Lead benzylcyanoacetate*, bulky cryst. ppt. with 3 H₂O; *calcium* and *barium* salts, needles with 3 and 6 H₂O; *copper salt*, deep blue ppt. with 5 H₂O which it loses at 65°, turning green, *m.* 105–15° (decompn.); *chloride*, slightly colored liquid, does not distil under 35 mm. at a bath temp. of 290°. (PhCH₂)₂(CN)CO₂H, *m.* 194–5° (Cassirer, *Ber.* 25, 3027(1892), gives 188–9°); *silver salt*, ppt.; *copper salt*, blue ppt. with 1 H₂O, turning green on drying. The *methyl ester*, 6-sided plates from Et₂O-ligroin, *m.* 78–9°, is obtained in 4.9 g. yield, together with 1.6 g. of the acid, when 20 g. NCCH₂CO₂Et in 125 cc. MeOH and 4.07 g. Na in 125 cc. MeOH are allowed to stand with 22 g. PhCH₂Cl 14 hrs. and the fraction *b*₁₈ 195–260° of the product is shaken in Et₂O with 10% NaOH.

FRANK P. UNDERHILL.

The Guthrie lecture. Some problems of living matter. W. B. HARDY. *Proc. Phys. Soc. London* 28, 99–118(1916).—The lecture deals with the phys. aspect of some of the phenomena of living matter. In drawing conclusions the possible effect of instinct or intelligence of the object experimented upon must be considered. Thus in expts. detg. the time lag of increased respiration of a cyclist it was found that the subject always anticipated the application of the load and the acceleration of his breathing commenced before the actual increase in effort instead of after. Many of the long accepted theories of the structure of living organisms were ultimately found to be due to the method of killing the organism and prepg. for examn. Exactly similar structures could be obtained in pieces of gelatin if treated in the same way. The principles underlying growth and development of organisms are outlined, and it is shown that growth depends on the presence in the food of vitamins. Thus in the case of white mice fed on artificial milk containing no vitamins growth ceased, while if 2% of ordinary milk were added to the artificial milk the growth rapidly became normal.

In pure distd. water it was impossible to obtain development of living organisms, but if the slightest trace of tap water were added certain organisms thrive normally. The fact that such small proportions of nutriment containing vitamins are sufficient suggests a parallel between their action and that of a few crystals thrown into a supersaturated soln. of a salt in initiating crystn. of the whole. Many other phenomena are described.

PAUL D. FOOTE.

Origin of the proteolytic ferments of the blood. LEROY H. SLOAN. Univ. Chicago. *Am. J. Physiol.* 39, 9-19(1915).—Polyvalent proteolytic enzymes occur in normal serum of males (dog and human) capable of producing demonstrable amts. of dialyzable digestion products after 40 to 44 hrs. incubation with human placenta. Under pathological conditions (especially wasting disease) these enzymes may be augmented to such an extent as to give a positive reaction within the time specified for the Abderhalden test for pregnancy. Serum from pregnant women and pregnant dogs reacted with dog pancreas and liver as well as with placental tissue, giving dialyzable digestion products within 16 to 20 hours. The increased proteolytic activity of serum during pregnancy is probably in the main due to an increase in the normal polyvalent enzymes rather than to the production of a specific ferment. At present the Abderhalden test for pregnancy is a quantitative, not a qualitative test.

J. F. LYMAN.

Ionic antagonism in sensory stimulation. W. J. CROZIER. Harvard Univ. *Am. J. Physiol.* 39, 297-302(1916).—An antagonistic action of ions is apparent in stimulating the foot of a pithed frog with mixts. of salt solns. C. concludes that in normal stimulation the essential step includes the penetration of the surface layer of the receptor by the stimulant.

J. F. LYMAN.

Mode of action of ultraviolet radiation in injuring living cells, with special reference to those constituting the eye. W. E. BURGE. Univ. Illinois. *Am. J. Physiol.* 39, 335-44(1916).—The effect of ultraviolet radiation on paramecia and egg white is to cause coagulation. The effective region of the spectrum lies between 254 and 302 $\mu\mu$. The eyes of frogs and fish living in tap water were not noticeably injured by 5 to 12 hrs. exposure to ultraviolet radiation, while the eyes of those animals living in solns. containing CaCl_2 , Na_2SiO_3 , or dextrose were made opaque by similar exposure. Abnormal amts. of the salts of Ca and Na_2SiO_3 in the cells of the eyelids and of the cornea increase the effectiveness of ultraviolet radiation in producing eye trouble. Abnormal amts. of Ca salts on the skin also increase the effectiveness of the short wave lengths in sunlight in producing sunburn.

J. F. LYMAN.

Coagulation of blood in the pleural cavity. G. P. DENNY AND G. R. MINOT. Johns Hopkins Med. School. *Am. J. Physiol.* 39, 455-8(1916).—"Blood which has been in the pleural cavity remains fluid not because of any alteration of the elements, but because of previous coagulation and defibrination."

J. F. LYMAN.

Nature of enzyme action. IV. Action of insoluble enzymes. W. M. BAYLESS. Univ. College, London. *J. Physiol.* 50, 85-94(1915); cf. C. A. 7, 3764.—Enzyme action takes place at the interface of contact between the solid enzyme phase and the liquid substrate phase; the catalysts concerned are not in true soln. Supporting evidence was obtained by showing that urease, lipase, emulsin, invertase, lactase, papain, peroxidase and catalase were active in media (usually 70 to 80% alc.) from which they could be filtered off by ordinary filter paper while the filtrates were inactive.

J. F. LYMAN.

Reaction of bile. S. OKADA. Univ. Coll., London. *J. Physiol.* 50, 114-8(1915).—The H ion concn. of gall bladder bile from the dog, ox, cat and sheep varies between 4.7×10^{-8} and 3.4×10^{-8} and may therefore be acid, neutral or alk. In fasting acidity is higher than after feeding. Dog bile collected from the liver during fasting had a

H ion concn. of from 3.9×10^{-8} to 7.2×10^{-9} ; during digestion the H ion concn. was between 2.9×10^{-8} and 1.0×10^{-8} , hence alk. to about the same extent as pancreatic and intestinal juices. Various kinds of foods had no perceptible effect on acidity of liver bile.

J. F. LYMAN.

Effect of isotonic Ringer solution on blood corpuscles. F. H. SCOTT. Univ. Coll. London and Univ. Minn. *J. Physiol.* 50, 128-39(1915).—On diluting blood with isotonic Ringer soln. the compn. but not the vol. of the red corpuscles is changed. Analyses of the dil. sera show that N compds. diffuse from the corpuscles. These consist largely of a protein having pptn. limits similar to the albumins, but partly of non-protein N. The relative vol. of serum and corpuscles cannot be calcd. by comparing the N in the plasma or serum with that found in similar blood diluted definitely with salt solns.

J. F. LYMAN.

Inflammatory action of eel blood and bile on the eye. OBLATH. *Arch. ophthalmol.* 21, 457(1914); *Zentr. Biochem. Biophys.* 18, 347(1915).—Pronounced inflammation of the conjunctiva was produced by penetration of eel blood and gall into the eye. Eel gall caused slight conjunctivitis in rabbits. Eel gall has a hemolytic action which is, however, less than that of eel serum.

H. S. PAINE.

Action of enzymes. E. S. EDIE. *Brit. Med. J.* 1914, 2803; *Zentr. Biochem. Biophys.* 18, 343(1915).—E. proceeded on the hypothesis that pepsin and trypsin unite with protein through a junction by the same side chain, but that the sp. side chains of the digestive enzymes are distinguished by their behavior toward acid and alkali. Upon this assumption pepsin would be expected to combine with albumin in alk. soln., while trypsin would combine in acid soln.; in this case neither of the enzymes would have a digestive action on albumin. Pepsin would behave as the zymoid of trypsin. An excess of pepsin would inhibit the action of trypsin on albumin and an excess of trypsin would inhibit the digestion of albumin by pepsin in acid soln. The results of the expts. are considered to have confirmed this assumption. When pepsin was mixed with an excess of trypsin the action of the former on protein in acid soln. was inhibited. Boiled trypsin inhibited the action of fresh trypsin on fibrin but not its action on caseinogen. It appears, therefore, that trypsin combines with fibrin by side chains which are more resistant to heat than are those by means of which trypsin unites with caseinogen. An excess of pepsin inhibited the action of trypsin on proteins; boiled pepsin no longer had this action.

H. S. PAINE.

Enzyme action. Corrections. K. GEORGE FALK AND KANEMATSU SUGIURA. *J. Am. Chem. Soc.* 38, 921-2(1916).—In the course of the study of lipolytic actions, some of the results of which have been published, the N contents of certain solid preps. were detd. by Kober's aeration method which has since been shown to be unreliable (*C. A.* 10, 1201). These have now been detd. by the heat distn. method. The esterase preps. E II from castor beans (*C. A.* 9, 634) gave 16.2% N for the dried material, whether dialyzed 5 or 20 hrs., and 17.0% N for the ash-free material, instead of 15.7 and 16.3%. The lipase preps. L I gave 16.8% N for the dried material and 17.9% N (instead of 17.0%) for moisture- and ash-free material. The corresponding values for L II are 17.1 and 17.9% (instead of 16.7%), and for L II reprecipitated from NaCl 18.2 and 18.4% (instead of 17.6%). The lipase prep. from soy beans (*C. A.* 9, 1922) gave 15.5% for the dry material instead of 14.0%. The corrected values approximate more nearly the analyses of similar substances described by Osborne and others.

C. A. R.

Nitrogenous constituents of brain lecithin. J. E. DARRAH AND C. G. MACARTHUR. *J. Am. Chem. Soc.* 38, 922-30(1916).—Fresh, finely ground sheep and beef brains were allowed to stand 2 days in Me_2CO , pressed out, the Me_2CO treatment repeated at least

twice more, the dehydrated material dried in a current of air, shaken twice 2-4 hrs with 2 vols. C_6H_6 (some of the extns. were made at 65°), the C_6H_6 evapd. almost to dryness under reduced pressure in CO_2 and the residue dissolved in the smallest possible amt. of Et_2O ; addition of 2.5 vols. $EtOH$ pptd. cephalin; the filtrate was evapd. almost to dryness under reduced pressure in CO_2 , the residue dissolved in a little Et_2O and treated with 2 vols. Me_2CO , which pptd. lecithin and some "white material;" after drying in darkened vacuum desiccators, the ppt. was allowed to stand overnight in Et_2O , when the "white material" sepd. out. The $EtOH$ and Et_2O treatments had generally to be repeated to remove remaining cephalin and "white material." The lecithins so obtained were hydrolyzed by boiling 15-20 hrs. in CO_2 with 3% HCl or 1.6-5.0% aq. KOH . The presence of $NH_2CH_2CH_2OH$ was demonstrated by means of the chloraurate and picrolonate which were found identical with the corresponding compds. prepd. from the synthetic alc. Choline was isolated as the chloroplatinate. In both beef and sheep brain, the choline N is about equal in amt. to that of the $NH_2CH_2CH_2OH$, the 2 comprising 85% of the total N in the lecithin; the other 15% is in the form of unhydrolyzable residue. If lecithin is a single substance (and it probably is not or is much more complex than is usually believed), it probably contains 1 mol. each of the above bases; this associated lecithin mol. is rather firmly combined with a satd. nitrogenous substance which it has as yet been impossible to remove.

C. A. ROULLER.

B. METHODS AND APPARATUS.

STANLEY R. BENEDICT.

An improvement of the phenolphthalin reaction for the demonstration of occult blood in feces. J. BOAS. *Deut. med. Wochschr.* 41, 549-50(1915).—The phenolphthalin reagent is prepd. by dissolving 25 g. KOH in 100 cc. distd. H_2O , to which is added 1 g. phenolphthalin (Kahlbaum). This soln. is not entirely colorless. It is heated with addition of metallic Zn until it is colorless. This is accomplished in 1-2 hours. After cooling the soln. is brought to the original vol. and filtered. This soln. keeps several weeks. The feces are extd. with alcohol-glacial acetic acid, adding 5 drops glacial acetic acid to 15-20 g. alc. To 15 drops of the phenolphthalin reagent in a test-tube are added 5-6 drops 3% H_2O_2 and 2 cc. absolute alc. and the mixt. shaken. The feces ext. is slowly run in along the side of the test-tube from the filter in order to obtain stratification. If blood is present in the feces sooner or later a pink to deep red ring is formed. Not more than 2-3 cc. acetic acid-alcohol ext. are needed. The test performed in this manner is very sensitive, but only for the examn. of feces. In order to be applied to the examn. of stomach contents it is necessary to ext. these with a mixt. of glacial acetic acid and ether. Good results are obtained with a glacial acetic acid-alcohol ext. of stomach contents tested with guaiac tincture.

S. AMBERG.

Examination of lumbar puncture fluid in cases of tuberculous meningitis by means of the ninhydrin reaction. E. NOBEL. *Münch. med. Wochschr.* 62, 1786 (1915).—In answer to the remarks of Kafka, N. defends the ninhydrin reaction of the cerebrospinal fluid in cases of tuberculous meningitis. When properly carried out, it is of differential diagnostic value.

S. AMBERG.

Estimates of cholesterol in serum by gravimetric and colorimetric methods. P. G. WYSON. State Hosp., Penn. *J. Med. Res.* 29, 457-64(1913); cf. C. A. 6, 1643.—Colorimetric and gravimetric detns. were made of pure cholesterol, impure cholesterol extd. from serum and impure cholesterol extd. from serum plus a known quantity of pure cholesterol. Known quantities of pure cholesterol subjected to the same process as that employed in the extn. of cholesterol from serum yielded 99.44% according to the colorimetric estimates and 108.56% by wt. Serum to which 1 mg. of pure cholesterol had been added to each cc. yielded an excess of 1 mg. per cc., according to the

colorimetric method and an excess of 1.3835 mg. by wt. In the 17 expts. in which a known quantity of cholesterol was estd. by both methods, the results obtained by colorimetric estn. were uniformly more accurate than the results obtained by wt.

GEO. T. CALDWELL.

Detection and determination of lead in the organism. FAUCONNIER. *Bull. soc. pharm. Bordeaux*, July, 1914; *Ann. chim. anal.*, 20, 126-7(1915); *J. Soc. Chem. Ind.* 34, 1032(1915).—F. proposes the following method: Treat 100 g. (from 20 to 200 g. may be used) of the substance by the $\text{HNO}_3\text{-H}_2\text{SO}_4$ method modified by Denigès, letting it stand 24 hrs. with a mixt. of 90 cc. H_2SO_4 and 10 cc. HNO_3 . Heat until completely decolorized. After cooling the remaining 20 cc. of soln., add 50 cc. H_2O , and neutralize with NH_3 . Dissolve the reddish ppt. in HCl , and pass in washed H_2S . After 24 hrs. filter, wash until the filtrate gives no color with KCNS and treat the filter and ppt. with dil. HNO_3 ; then evap. to dryness, take up in a little H_2O , filter through glass wool and wash until the filtrate has a vol. of 90 cc. Add 3 cc. satd. KCNS , ext. in a separatory funnel with successive portions of ether until the red color is removed and drive out ether by heating on a H_2O bath. Cool and make up to 100 cc. Det. the Pb colorimetrically with Na_2S and KCN soln. F. found in a normal liver weighing 1250 g., 0.0062 g. Pb.; in a brain of 1160 g., 0.0024 g.; kidney of 115 g., 0.00026 g.; placenta of 420 g., 0.000388 g.; in an artichoke of 215 g., 0.0029 g. P. M. GIESY.

Comparative study of aeration and heat distillation in the Kjeldahl method for the determination of nitrogen. K. GEORGE FALK AND KANEMATSU SUGIURA. *J. Am. Chem. Soc.* 38, 916-21(1916).—In the aeration expts., carried out strictly under the conditions stated by Kober to be the most satisfactory (*C. A.* 7, 3981), not only were the results obtained compared with the calcd. values for pure substances wherever possible and with those obtained by heat distn., but every soln. which had been aerated was then submitted to heat distn. With casein, meningitis, tetanus and streptococcus antitoxin preps., castor bean globulin, hexamethylenetetramine, uric acid, glycylglycine, alanylglycine, tyrosine, glycine, alanine and urea, only in the case of the tetanus antitoxin prep. and of the tyrosine were the results obtained by aeration satisfactory, the % of N being increased 0.10-0.27 by subsequent heat distn. For the other substances the results by the aeration method were 0.30-1.97% low; subsequent steam distn. brought them up to values agreeing satisfactorily with those obtained by heat distn. alone. With different proteins, the aeration method alone gave results 0.40-1.50% lower than those obtained by heat distn. The following mixts. were then made up, each with approx. 0.1 g. $(\text{NH}_4)_2\text{SO}_4$, dild. to 175 cc. and containing: (1) varying amts. of NaOH , d. 1.444; (2) 20 cc. concd. H_2SO_4 , 10 g. K_2SO_4 , 0.2 g. $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ and varying amts. of NaOH , d. 1.444 and 1.470; (3) 10 g. K_2SO_4 , 0.2 g. $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$, 75 cc. NaOH , d. 1.461, and 10-20 cc. H_2SO_4 . In (1) distn. by the aeration method was incomplete with less than 55 cc. NaOH , in (2) incomplete with 75 cc. NaOH of either concn., and in (3) complete in all cases. C. A. ROUILLER.

Detection of picric acid in urine in presence or absence of biliary pigments. VILLEDIEU AND MANCREAU. *Arch. de méd. et pharm. milit.* 64, 255(1915); *J. pharm. chim.* 12, 366(1915).—To 100 cc. urine add 20 cc. of a satd. soln. of BaCl_2 , shake well and filter. Dissolve the Ba picrate on the filter with 10-15 cc. of boiling H_2O and wash out. To the filtrate add excess of H_2SO_4 (about 5 cc.). After sepg. the ppt., shake out picric acid with 2×20 cc. Et_2O , evap. and take up residue with 2 cc. of boiling H_2O , filter and identify picric acid in the yellow soln. by 3 tests: (1) Mix on watch glass 2 drops of the liquid with 2 drops of 10% soln. of HCl -cocaine and observe silky crystals of cocaine picrate under microscope. (2) To 10 drops of soln. add 2-3 drops of alk. soln. of KCN ; warming produces dark red color. (3) Dil. 10 drops of the soln. with H_2O ,

strains that are easily and rapidly agglutinated by means of immune sera are likewise easily and rapidly pptd. by H^+ , probably of a concn. 3.6×10^{-4} . The H^+ test may sometimes aid in the detn. of *B. typhosus*. However, it can never be a certain test. It cannot be used as a practical method of pptg. *B. typhosus* from contaminated H_2O . It indicates a possible source of error in performing an agglutination test with typhoid bacilli.

JULIAN H. LEWIS.

Enzymes of a cellulose-destroying fungus from the soil, *Penicillium pinophilum*. E. D. CLARKE AND F. M. SCALES. U. S. Dept. Agric., Washington, D. C. *Proc. Soc. Biol. Chem.* 1915; *J. Biol. Chem.* 24, xxxi(1916).—From fungous mats on the surfaces of nutrient solns., "acetondauer" preps. were made from *Penicillium pinophilum*. A modified neutral Raulin soln. was used as a nutrient medium, to which acid-washed filter paper was added as a source of C. This cellulose was attacked in 2 to 3 weeks of growth. Aq. exts. of powdered fungous material showed especially active enzymes like sucrase, emulsin and amidase, while diastase, catalase and lipase were present but not as active. Tests for peptic, tryptic and ereptic enzymes, and also peroxidase, gave negative results but it is not likely that such enzymes would be absent in the living fungus which certainly attacks protein, etc. Most of the enzymes found were studied by quant. methods. The most active prepn. was made from a growth for 3 weeks on inorg. nutrient soln. containing $(NH_4)_2SO_4$ and cellulose as sources of N and C.

A. P. LOTHEROP.

Investigation of the restrictive action of poisons on microorganisms. V. Action of "Hg-chlorphenol," sublimate, antinonin, mycantin and formaldehyde on wood fungi, *Aspergillus niger* and bacteria. C. WEHMER. Hanover. *Chem. Ztg.* 40, 89-91, 106-8(1916).—The object of the work was a better comparison of the action of so-called fungus poisons, and to find the concn. necessary to prevent the development of spores on sterile aromatic gelatin. The fungi used were *Merulius lacrymans*, *Polyporus vaporarius*, *Coniophora cerebella* and *Trametes radiciperda* in pure cultures. *Aspergillus niger* was used as a substitute for mold fungus. The bacteria were not in pure culture. Methods are described and the results tabulated. The conclusions for the conditions of these expts. are that *Merulius*, *Coniophora*, *Trametes* and *Polyporus* were most affected by antinonin, mycantin, raco, and microsol (all containing nitro compds.); of these fungi, *Trametes* was most affected by the other reagents. With *Aspergillus* the Hg compds. were nearly twice as effective as the nitro compds., $HCHO$ closely following the former. Bacteria and yeasts were also much more affected by Hg compds. Cf. C. A. 8, 726, 1336, 1808.

J. H. MOORE.

Biological studies of the intestinal flora of infants. KURT BLÜHDORN. Göttingen *Monatsschr. Kinderheilk.* 13, 297-350(1915); *Zentr. Biochem. Biophys.* 18, 168(1915).—B. studied the influence of albumin and N on carbohydrate fermentation by bacteria, the process of fermentation in the presence of various mixts. of bacteria in varying dilns. of milk was first studied. Bacteria decompd. only a definite amt. of sugar in a given time; the amt. of added sugar was without influence on acid formation. The N content was, however, of determinative influence; bacterial growth also increased with the acid content in the case of increasing amts. of albumin. B. employed various sources of N such as asparagine, nutrose, peptone, plasmon and $(NH_4)_2SO_4$; these sources of N increased the production of acid in varying degree when they were employed in amts. of equiv. N content. Peptone was more effective than plasma and nutrose in producing acid. Urea caused no increase in acid production and a decrease was sometimes observed even when considerable bacterial growth was evident. A comparative expt. with human and cow milks showed that a relatively high degree of acidity was produced by the former. The expts. showed in general that decompn. of sugar increased

with the amt. of N which was available. In a 2nd series of expts. B. studied the fermentation of various carbohydrates. Maltose and lactose were more readily attacked by the intestinal flora of nurlings than was sucrose. Malt ext. produced greater acidity than maltose; this difference is ascribed to the N content of the malt ext. B. tested the influence of various acids on bacterial flora. Lactic acid had the greatest inhibiting action in smaller concns., while AcOH and butyric acid had only a slight action in this respect. The inhibiting action of acids was diminished by addition of peptone. Succinic acid and H_2PO_4 had the slightest inhibiting effect. B. further discusses the pathogenesis of intestinal affections of nurlings.

H. S. PAINE.

Intensification of natural decomposition after death. F. BORDAS AND S. BRUERE. *Bull. Acad. Med.* 75, No. 1(1916); *J. Am. Med. Assoc.* 66, 694.—Decompn. of corpses can be much hastened by lining the grave or ditch with straw to preserve the heat from the microbial fermentation processes. The straw should be well watered with cultures of bacteria that decompose urea. Admission of a little air promotes the decompn.

L. W. RIGGS.

Importance of *Bacterium bulgaricus* group in ensilage. O. W. HUNTER AND L. D. BUSHNELL. *Kansas State Agr. Coll. Science* 43, 318-20(1916).—Several hundred bacteriologic analyses of different kinds of ensilage at all stages of fermentation indicate the importance of this Bulgarian group in the ripening of normal ensilage. Plate cultures upon acidulated glucose agar produced colonies similar in many respects to the common *B. lactis acidii* colonies. This is probably one reason why *B. bulgaricus* has been overlooked by other investigators. A good growth is observed in 1-4 days in glucose broth inoculated directly from a colony, while a litmus milk culture from a similar origin is coagulated only after 2-14 days' incubation. Peptone added to the milk favors their growth, coagulation and acid production being much more prompt. A table is given showing the rate and amt. of acidity developed in plain and in 1% peptone milk; also a chart showing the Bulgarian type to be more than 90% of the total bacteria present.

L. W. RIGGS.

Diastase activity and invertase activity of bacteria. G. P. KOCH. *Soil Science* 1, 179-96(1916).—Enzymes detd. as diastases and invertase are secreted by bacteria in culture solns. in amt. sufficient to be detd. quantitatively. There is considerable variation in the activity of enzymes secreted by bacteria when they are developed in culture solns. of different compn. There seems to be no direct correlation between hydrolytic enzyme secretion and protein decompn. by bacteria. Enzyme activity of different species of bacteria varies greatly. There is no direct correlation between hydrolytic enzyme secretion and the property of the soln. to rotate the plane of polarized light, the % of reducing compds. present, the formation of acid and the number of organisms. Bacteria do not produce a surplus of reducing compds. in the soln.

J. J. SKINNER.

D. BOTANY.

CARL L. ALSBERG.

Recent investigations on the protoplasm of plant cells and its colloidal properties. F. CZAPPEK. *Ann. Missouri Bot. Gard.* 2, 241-52(1915).—Reviewing critically earlier and recent contributions, C. holds that living protoplasm must be considered as a colloidal emulsion of lipoids in hydrocolloidal media, the latter contg. proteins and mineral salts.

E. J. C.

The role and function of mineral salts in plant life. D. M. RABINOVITCH. *Inst. Bot. Univ. Geneva* [11] 8, 24 pp.(1914); through *Expt. Sta. Record* 34, 135.—R. reports a study on the assimilation of nutritive mineral materials by *Raphanus sativus*, also on the influence of $CaCO_3$ and $MgCO_3$ on the development of *Digitalis purpurea*.

The results with *R. sativus*, as shown by analysis after stated periods, are presented in tabular and graphical form. The tests with *D. purpurea* show increasingly injurious results corresponding to an increase of CaCO_3 or of a mixt. in equal proportions of this salt with MgCO_3 , but the increase of injury was much less marked when dolomite was substituted for the mixt. The toxic effect seems to be correlated with the degree of alkalinity.

E. J. C.

Albuminous crystalloids in potato leaves. HELENA HUBERT. *Oesterr. Bot. Z.* 64, 273-7(1914); through *Expt. Sta. Record* 33, 824.—The formation of albuminous crystalloids is plentiful in young leaves of potato plants grown from tubers in darkness and moisture, but much less so in plants grown in light. The crystalloids diminish rapidly in etiolated plants after these are exposed to light. The crystalloids, which appear only in the leaves, are abundant in the intumescences on the leaf surfaces, also in the interior portions of the leaf, when grown under glass, but they disappear with the shrinking of the intumescences.

E. J. C.

Lipase in the germinating coconut. M. L. ROXAS. *Philippine Agr. and Forestry* 3, 33-9(1914); through *Expt. Sta. Record* 33, 426.—The results are given of a study in which R. found that lipase was present both as an enzyme and a zymogen in germinating coconuts. It occurs mainly in the outer part of the haustorium, smaller amts. being found in the water of the coconut and in the inner surface of the endosperm.

E. J. C.

The action of antimoniacal salts on the respiration of plants. W. PALLADI AND G. COHNSTAMM. *Rev. gen. botan.* 25, 539-55(1914); *Expt. Sta. Record* 33, 30.—The authors found that the respiration of etiolated shoot tips of vetch is stimulated by 1% of Sb tartrate, as by other poisons (C. A. 4, 3082), presumably as a defensive reaction against the poison, while the respiration of germinating peas is decreased by that soln. The difference is ascribed to the deficiency of respiratory chromogens in peas, and the consequent lessened absorption of O by them. The normal coeff. of respiration is but little affected in seeds of peas and shoots of vetch by this poison, but in young rootlets of sprouting peas, which normally show the coeff. $\text{CO}_2:\text{O}_2 = 1:2$, the coeff. becomes $\text{CO}_2:\text{O}_2 = 1$, corresponding to a decrease in growth rate. The action of this salt decreases the respiration of dead cells. Seeds poisoned with Sb after freezing give off a decreased amt. of CO_2 .

E. J. C.

Anthocyan in plants. V. GRAFE. *Umschau* 18, 643-6(1914); *Expt. Sta. Record* 33, 824.—This is a discussion of contributions by several authors mentioned regarding the presence, compn., and significance of anthocyanins in plant cells.

E. J. C.

The rate of absorption of various phenolic solutions by seeds of *Hordeum vulgare* and the factors governing the rate of diffusion of aqueous solutions across semi-permeable membranes. A. J. BROWN AND F. TINKER. *Proc. Roy. Soc. London (B)* 89, 119-35(1915).—When dry barley seeds are immersed in solns. of most inorg. acids and salts, sugars, etc., water alone passes into the seed. With certain phenols, fatty acids, and monohydric alcohols, solvent and solute enter the seed together. This property of selective permeability makes the seed valuable in the study of some of the phenomena of osmosis. The following substances were chosen because: (a) the membrane of the barley seed is permeable to them all; (b) some of their physical properties are strikingly diverse while others are practically identical; (c) they have a negligible ionization. The rate of absorption of 0.5 N solns. at 19° was greatest in the case of phenol, and decreased in the order: resorcinol, quinol, pyrogallol, the last being identical with pure water. For solns. of absorption were increased, but < 0.5 N the rate decreases with the concentration of the first order. The rate of absorption was unchanged.

differences in the viscosities, vapor pressures, and osmotic pressures of the solns. were too small to account for the great differences in the rates of absorption, while the surface tension varied widely. The conclusion from the comparison of these phys. properties was that when the osmotic pressures, vapor pressures, and viscosities of a series of permeating solutes were equal, their rates of diffusion across the barley membrane were inversely proportional to their surface tensions. In terms of the Laplace theory of capillarity this implies that the solute mols. have diminished the mutual attraction of the solvent mols. The solvent mols. will, therefore, diffuse more readily over the surface of the barley membrane. These considerations must be confined to solns. of solutes which permeate the membrane, and not extended to osmotic phenomena as a whole, as I. Traube has attempted to do.

H. W. BANKS, 3D.

New Observations on beet and potato tyrosinase. M. GONNERMANN. Rostock. *Chem. Ztg.* 40, 127-8(1916).—Expts. with sheep, chicken, guinea pig and human blood showed that potato tyrosinase is a simple compd. It acts as an oxidase on FeSO₄ and pyrocatechol more vigorously than the beet tyrosinase and has the property of agglutinating blood corpuscles. The beet tyrosinase is combined with a hemolyzing saponin.

J. H. MOORE.

Influence of temperature and light on coloration by anthocyanin. L. v. PORTHEIM. Vienna. *Ans. Akad. Wiss. Wien, Math.-Naturwiss. Klasse* 15, 327-9(1914); *Zentr. Biochem. Biophys.* 18, 307(1915).—Expts. which were performed with numerous plants (seedlings of red cabbage and blossoms of the elder, rose, iris, corn flower, violet, etc.) showed in general that the most intense colorations appeared at the lower temps. Temps. of 15° and up either caused more or less pronounced decolorization or the appearance of a reddish tint. Boiling of pigment exts. of a given plant in distd. H₂O caused the appearance of colors of different intensity and *nuances* than were produced by boiling in 75% alc. The color intensity of the alc. exts. diminished with decrease in temp. and increased with rising temp. Color changes which appeared on diln. of aq. exts. indicated that there is a connection between the concn. and the color of the solns. Aq. and alc. exts. which had been exposed to light exhibited colorations of a more bluish tint than did those which had been kept in the dark; the latter showed more pronounced reddish tints. This modification appeared to be quite as reversible as were those changes which depended upon variation in temp.

H. S. PAINE.

Behavior of tannin in the assimilation organs of Leguminosae during development. A. KOLBE. Göttingen. *Inaug. Diss. Göttingen* 1914, 97 pp.; *Zentr. Biochem. Biophys.* 18, 303(1915).—Certain regularities were observed in the appearance and behavior of tannin in the assimilation organs of Leguminosae. Little or no tannin was detected in the earliest stages in the extremely numerous exptl. objects which were examd. Increase in the amt. of tannin was observed at the beginning of the period of extension of the assimilation organs and even in the 1st stages thereof. The amt. of tannin then decreased; the period at which the max. tannin content was reached was subject to slight variations. Other factors, such as illumination, nutrition and period of the yr. also influenced the formation of tannin; these factors did not, however, modify the general rule that the behavior of tannin is dependent on the stage of development of the assimilation organ in question.

H. S. PAINE.

Fixation of photographs in leaves. H. MOLISCH. Vienna. *Sitzb. Akad. Wiss. Wien, Abt. I* 123, 923-30(1914); *Zentr. Biochem. Biophys.* 18, 304-5(1915).—M. fastened sharply defined negatives of various photographs on the leaves of *Tropaeolum majus* and exposed the plants to direct sunlight for 1 day; in the evening the leaves were subjected to the Sachs I test. Under these conditions the positive of the image appeared upon the leaf. The image was so sharply defined

that individuals could be readily recognized in the case of photographs of persons; it was possible to preserve the photographs. This expt. proves that the formation of starch varies in the most sensitive manner with the intensity of light. M. did not attempt the further expt. of using the leaf as a photographic plate in the camera and producing a negative directly in the leaf. H. S. PAINE.

Anthocyanic substances. O. GERTZ. Lund. *Svensk Bot. Tidskr.* 8, 405-35(1914); *Zentr. Biochem. Biophys.* 18, 306-7(1915).—G. studied numerous plants containing anthocyanin (*Asolla caroliniana*, *Tradescantia discolor*, *Clivia nobilis*, *Fagus sylvatica*, *Pelargonium zonale*, *Cobaea scandens*, etc.) belonging to the most varied divisions of the plant kingdom. Anthocyanin was usually found to be present in soln. in the cell-fluid; it frequently occurs, however, in solid form, e. g., in amorphous bodies of varied shape or crystallized in single crystals as raphides, dendrites and trichites. Sepn. in solid form occurs through supersatn. of the cell-fluid as a result of increased pigment formation, decreased H₂O content (e. g., in pronounced transpiration) or the action of low temps. In addition to substances which consisted exclusively of anthocyanin G. observed others (e. g., proteins and tannins) which were only colored with the pigment. G. succeeded in artificially producing anthocyanic substances by cell plasmolysis.

H. S. PAINE.

Fluorine in the vegetable kingdom. A. GAUTIER AND P. CLAUSMANN. *Compt. rend.* 162, 105-12(1916); cf. *C. A.* 6, 2727, 2900; 7, 2782, 3518; 8, 1451, 2911; 9, 829, 1361.—The authors' object was to det. all plants contained F, whether the F was more abundant in certain parts or organs than in others, the quant. relations of P to F, and the relation of different orders to the F content. In 63 analyses, mostly of food plants, F was found in every case, the amt. ranging from 0.059 to 13.87 mg. in 100 g. of the dried material, the av. being 2.65 mg. F is most abundant in the leaves. Large or small amts. do not seem to be characteristic of any particular order. The skins of the apple and banana contain more than 10 times as much F as the pulp. P was detd. in 36 of the samples and ranged from 8.7 to 1237 mg. in 100 g. of the dried material. A large P content was generally associated with a large F content. The ratio of P to F is more variable in plant than in animal tissues. L. W. RIGGS.

Preliminary notes on the carbohydrates of the Musci. T. G. MASON. *Sci. Proc. Roy. Dublin Soc.* 15, 13-28(1916).—Alc. solns. of 3 varieties of Musci (*Polytrichum commune*, *Thuidium tamariscinum*, and *Sphagnum cymbifolium*) showed the presence of invertase in each case, while the first showed maltase and diastase also. The mosses were boiled in alc. for 10 min. to destroy enzymes and then extd. for 24 hrs. with alc. after first adding CaCO₃ to neutralize the acids present. The residue was then subjected to extn. for 24 hrs. with H₂O, the exts. united and the alc. distd. off. The soln. was then treated with basic Pb acetate and alumina cream, the gums and tannins filtered off and the filtrate (Pb removed with Na₂CO₃) concd. and made up to the required vol., after which the soln. was examd. qual. and quant. The concn. of the soln. browned the levulose present so the sugars were detd. by Benedict's Na-citrate method (cf. *C. A.* 5, 2256). The amts. of sugars for *P. commune* were found to be: 2.17% hexoses (dextrose and levulose), 1.36% sucrose and 1.36% maltose. Plants kept for some time in the dark showed a great decrease (to 0.59%) in the amt. of sucrose and a slight decrease in amts. of hexoses and of maltose. It was shown that sucrose is the first sugar to increase on illumination. It is probable that the hexoses are the chief form in which carbohydrates descend the stem. R. I. SIBLEY.

The exchange of ions between the roots of *Lupinus albus* and culture solutions containing two nutrient salts. R. H. TRUE AND H. H. BARTLETT. *Am. J. Botany* 2, 311-23(1915).—In growing *Lupinus albus* in culture solns. in which the nitrates of Ca, Mg

and K are used in pairs the roots absorb more electrolytes than from the pure solns. The absorption tends to increase in mixts. as well as in pure solns. as the salt content increases. In mixtures of $\text{Ca}(\text{NO}_3)_2$ and KNO_3 the inimical effect of K ions on root absorption is seen in the high ratio of Ca to K required to give max. absorption. The value of a small amt. of K ion is, however, proved by the excess of absorption in the mixt. over that in $\text{Ca}(\text{NO}_3)_2$ alone. The abs. amt. of Ca present in mixts. seems to have great influence since, as the proportion of Ca increases in the greater diln., absorption is increased. In pure solns. the Mg ion is much more favorable to absorption than the K ion in the weaker concns., while the K ion is more favorable in the highest concn. They are absorbed to about the same content at a concn. of $360 \times 10^{-6} N$. Absorption from mixts. exceeds that from either pure soln. except in the weakest concn. See C. A. 9, 2396. J. J. SKINNER.

Some relations of plants to distilled water and certain dilute toxic solutions. M. C. MERRILL. *Ann. Missouri Bot. Gardens* 2, 456-500(1915).—This is a detailed account of work previously briefly presented (C. A. 9, 2103). An historical review is given of the views held in regard to the cause of injury to plants in distd. H_2O . Working with *Pisum sativum* and *Vicia faba* it was found that renewing distd. H_2O of the cultures every 4 days was beneficial. The plants were able to survive longer in renewed than in unrenewed H_2O . Sterilizing the H_2O by boiling every 4 days exercised a beneficial effect upon growth in that medium as compared with growth of those in unsterilized distd. H_2O . The greatest exosmosis was obtained in the case of those cultures in which the distd. H_2O was renewed. There was a readsorption of electrolytes in the cultures when the distd. H_2O was not renewed. J. J. SKINNER.

Electrolytic determination of exosmosis from the roots of plants subjected to the action of various agents. M. C. MERRILL. *Ann. Missouri Bot. Gardens* 2, 507-72 (1915).—A review is given of the subject of excretion from plant roots, exosmosis from living cells, and of excretion from leaves and other tissue. Pea seedlings grew better in distd. H_2O in which exosmosis from the treated plants of the 1st crop had occurred than in fresh distd. H_2O . Peas and beans did not grow as well in H_2O in which pea seedlings had already grown for 21 days as in freshly distd. H_2O . Long exposure of the plants to anesthetic vapors causes marked exosmosis. The exosmosis curves for various org. compounds were found. Marked excretion was produced. The effect of single salts, salts in pairs, and salts plus anesthetics in soln. were ascertained as regards exosmosis produced upon the plants in such solns. Antagonistic relations in the sense that one substance decreased the exosmotic effect produced by another substance were found not to hold. Cf. C. A. 9, 2103. J. J. SKINNER.

Toxicity of galactose for certain higher plants. L. KNUDSON. *Ann. Missouri Bot. Gardens* 2, 659-66(1915).—Working with a nutrient culture soln., galactose proved harmful to vetch (*Vicia villosa*) and peas (*Pisum sativum*) but the other sugars, glucose, lactose, raffinose, sucrose and maltose were beneficial when used in concn. of 2%. Galactose was harmful when used in concn. of 1% and more; below 1% it had no effect. J. J. SKINNER.

Fixation of ammonia by cell albumin. T. BOKORNY. *Biol. Centr.* 35, 25-30 (1915); *Expt. Sta. Record* 34, 30.—B. states that his previous conclusions (C. A. 7, 628) have been confirmed. This supports the view that tobacco smoke causes injury to plants largely through its content of NH_3 , which belongs to that class of compds. which are injurious to living protoplasm when present in very small proportions on account of their ready combination with the albuminous components of the cell. E. J. C.

E. NUTRITION.

PHILIP B. HAWK.

NORMAL.

Vitamines and accessory foods. BORUTTAU. *Ber. pharm. Ges.* 25, 468-86(1915).—An address (cf. *C. A.* 10, 490). W. O. E.

Soy bean in infant feeding. J. F. SINCLAIR. Phila. *N. Y. State J. Med.* 16, No. 2(1916); *J. Am. Med. Assoc.* 66, 841.—The experience of S. leads him to recommend soy beans as food in the treatment of summer diarrhea, various intestinal disturbances, and in marasmus. L. W. RIGGS.

Citrated whole milk method in feeding infants. E. PRITCHARD. *Practitioner* 96, No. 2(1916); *J. Am. Med. Assoc.* 66, 774.—P. regards this method as physiologically unsound, since it allows no latitude for adaptation to the individual's digestive, assimilative, metabolic and secretory activities. If the principles of percentage feeding are understood, a satisfactory food can be synthesized in many ways to satisfy the physiologic requirements of any particular child. Dried milk if properly modified and of good quality has all of the advantages and few of the disadvantages of citrated whole milk. L. W. RIGGS.

Undiluted citrated milk in feeding of infants. R. CARTER. *Practitioner* 96, No. 2(1916); *J. Am. Med. Assoc.* 66, 774.—C. gives undild. sterilized milk in amt. equal to 0.1 of the body wt., insists on clock-like regularity of feeding, and makes the intervals between feeding as long as possible. One grain of $\text{Na}_2\text{C}_2\text{H}_3\text{O}_7$ per ounce of milk is used instead of the generally accepted 2 grains. The milk is sterilized by receiving it in a clean jug, placing the jug in a vessel of water and allowing the water to boil 5 min. L. W. RIGGS.

Effects of commercial glucose when fed to white rats. A. J. CARLSON, L. HEKTOEN AND E. R. LECOUNT. *J. Am. Chem. Soc.* 38, 930-6(1916).—White rats were fed for a period of six months with bread containing a certain amt. of glucose, besides carrots or other vegetables and occasionally meat, while one set of controls was given bread containing cane sugar and another set bread with no sugar. The % increase in body wt. for the 3 sets was 122, 131.8, 123.5, resp.; for some reason, the number of young born in the 1st group was larger than that in the other 2; this probably accounts for slightly lower rate of growth in the former. As the rats were given as much food as they would eat and this was probably more than the minimum required for growth and maintenance, the expts. do not show to what extent the glucose is absorbed and oxidized but in the absence of definite expts. to the contrary it is justifiable to conclude that the greater part of the dextrins and the dextrose in com. glucose are utilized in the carbohydrate metabolism of the body. As to the question of deleterious by-products and contaminations, however, the above expts. seem conclusive. In the 3 groups there was practically no difference in the rate of growth, resistance to infection and in the production of antibody against sheep corpuscles. Postmortem examn. revealed no lesion that could be traced to the diet in any group, although the quantity of glucose consumed per day, covering a period of about $\frac{1}{4}$ the total span of life of the rat, was 2.5-3.5 g. per kg. body wt. The question of palatability does not enter in the use of glucose in bakery products and confections. CHAS. A. ROUILLER.

Resorption of hydrolytic products of proteins by the intestine. I. Investigations of the surviving small intestine perfused with Tyrode solution. TULLIO GAYDA. Turin. *Arch. fisiol.* 13, 83-115(1914); *Zentr. Biochem. Biophys.* 18, 167(1915).—When a mixt. of amino acids obtained from complete hydrolysis of meat was injected into a surviving small intestine (of the cat) which was perfused with Tyrode soln. the liquid which flowed from the mesenteric vein and thoracic duct had a considerably higher

content of total N and amino N than was observed when H₂O alone was injected into the intestine. The liquid which issued from the thoracic duct, moreover, showed traces of proteins (especially when amino acids were injected into the intestine); in no case did the outflowing liquid contain NH₃. The ratio of amino N to absorbed total N was less than the ratio of amino N to the total N of the injected amino acid mixt. This result is due either to selective action in the absorption of the various amino acids or nitrogenous substances which are present in the injected soln. or to the formation of peculiar complexes from the absorbed amino acids (but not, however, to synthesis of proteins). Only a relatively small amt. of the injected amino acids passed unchanged from the intestine into the perfusing nutrient fluid.

ABNORMAL.

Dietetic treatment of beriberi in the Dutch East Indies. D. J. H. POL. *Norsk Mag. Laegevidenskaben* 77, No. 1(1916); *J. Am. Med. Assoc.* 66, 698.—Large amts. of purée of peas had an unmistakably curative action on beriberi. As much as 150 g. of the purée 3 times a day was required, smaller amts. showing no benefit. Oatmeal had a similar influence, but 125 g. 3 times a day was necessary. Europeans required a little less. A native bean seems also to have a like action. These 3 vegetables evidently contain the substance or substances the lack of which induces the disease. They lose their efficiency with age. Three-year-old beans were quite inert. Details are tabulated of 83 cases covering 33 pages.

The significance of the amount of low molecular glycerides of fatty acids in milk fat of various animals. E. GUTZERR. *Kühn Arch.* 5, 127-38(1914); *Expt. Sta. Record* 33, 803.—The Reichert-Meissl no. of human milk was found to be 2.03. This is in agreement with the findings of Laves (2.5) and Pizi (1.42), but not with Sauvaitre (15.8). The R.-M. no. of the fat in cow, sheep and goat milk is 2 or 2.5 times greater than that of the fat in ass and mare milk, and in the latter the R.-M. no. is 6 times as great as in human milk. Pig and dog milk contain still less of these volatile fatty acids. Accordingly, it is concluded that herbivorous animals require milk with fat which contains a high water-sol. volatile fatty acid content and the omnivorous and carnivorous animals a milk fat with a low one.

Leucocytosis by modifications of the blood gases and the suprarenals. MARIO CROVINI. Milan. *Arch. farm. sper.* 19, 448-66(1915).—Extirpation of the suprarenal capsules suppresses the leucocyte reaction to CO₂, both quantitatively and qualitatively. The reaction can then be restored by intravenous injection of adrenaline.

A. W. DOX.

The action of sugars on biliary secretion. D. LO MONACO. Univ. Rome. *Arch. farm. sper.* 21, 49-76(1916).—Ingested carbohydrates are without influence on biliary secretion for the reason that they are transformed into glycogen before they can exert a stimulating effect upon the hepatic cell. On the other hand, their injection into the circulation may result in an increased flow of bile. Small doses dilate the blood vessels and stimulate the hepatic cell, while large doses produce exactly the opposite effects.

A. W. DOX.

Nature of muscle recovery. J. PARNAS. Strasburg. *Zentr. Physiol.* 30, 1-18 (1915).—The cause of heat formation is the same as in respiration and the heat forma-

tion in resting muscle is const., while in previously tired muscle it rises at first and then falls to rest value. The abs. quantity of heat production in untired muscle is as great as the thermal equiv. of O consumption, while in the tired muscle it is about one-half as great as the heat equiv. of the combustion of its lactic acid. The O consumption of the tired muscle equals the complete oxidation of its lactic acid to CO_2 and H_2O . Muscle on recovery only sets free as heat about one-half of the energy its oxidative processes liberate. The other half of the energy is used to restore the physico-chem. condition of the tissue, in which it is stored as potential energy. This is, according to Hill, convertible to mechanical energy in full amt. The gastrocnemius of frog stores about 2 cal. per g. of tissue.

F. HULTON.

The influence of the vagus nerve on glycogen formation in the liver and a new method for investigation of the metabolism of the liver in its dependence on the nervous system. M. EROG. Bern. *Zentr. Physiol.* 30, 445-9(1915).—The under-surface of the shell was removed from a turtle and canulas inserted in the right and left umbilical veins. The liver is in 2 parts, connected by bridges of tissue 1 mm. thick. These were cut between ligatures with a hot knife, and the seared edges formed an impermeable crust; this practically gave 2 livers. The vein from the duodenum to the liver was bound off and a canula inserted in the middle vessel from the *bulbus arteriosus*. The right vagus was dissected out and laid on an electrode, while the left vagus was dissected out up to the liver, all visible branches destroyed and the whole region brushed with concd. PhOH to destroy all connections between the 2 vagi. A 1.5% dextrose soln. was perfused through both halves at const. pressure. The vagus was stimulated intermittently and finally a piece of liver was removed from each half. These were boiled 3 hrs. with hot 60% KOH soln. Glycogen was detd. according to Pflüger-Bertrand. There was an increase of glycogen in the stimulated half of 10-14%. E. expects to investigate purine and fat metabolism with this technic.

F. HULTON.

The time of appearance of adrenaline in the suprarenal capsules of the fetus. G. CAVOLORRO. *Atti r. ist. Veneto* 73, II, 1159-61.—The suprarenal capsules of ox, sheep, pig, and human fetuses were extd. with 5 times their wt. of Ringer soln. The presence of adrenaline was tested biologically on the isolated mammalian heart, which is just as sensitive as the frog eye, or strips of arteries, uterus, or intestine, the minimal quantity thus detected being 1:40,000,000. The results showed that adrenaline is formed before the middle of pregnancy. The earliest time of appearance of the hormone was not detd.

D. I. MACHT.

Presence of glycogen in the normal and pathological tissues of the human eye. CONTINO. *La clin. oculist.* 14, 1729(1914); *Zentr. Biochem. Biophys.* 18, 332(1915).—The nature of the distribution of glycogen in the eye of the sheep embryo indicates that its presence in ocular tissues is necessary in order that the differentiation which is characteristic of its later development may be acquired.

H. S. PAINE.

Occurrence of lactic acid in the saliva of infants. G. SALVETTI. Turin. *Riv. clin. pediatr.* 12, 418-24; *Zentr. Biochem. Biophys.* 18, 166(1915).—S. tested the correctness of the observations of Oshima regarding the occurrence of lactic acid in the oral cavity of infants. Freshly secreted saliva collected by means of an app. especially designed for the purpose was used for the expts. The occurrence of lactic acid in saliva appears to be exceptional, inasmuch as it was detected in only 2 out of 30 samples.

Histology of the uterus mucosa and the occurrence of fatty substances. S. ASCHHEIM. Berlin. *Z. Geburtshilk.* 77, 485-93(1915); *Zentr. Biochem. Biophys.* 18, 333(1915).—The occurrence of large amts. of lipoids in the uterus mucosa is principally

associated with the premenstrual period; the lipoids disappear from the epithelia with menstruation. A. discusses the various views regarding the significance of lipoids in the uterus mucosa.

H. S. PAINE.

Malignant dog struma and the secretory activity of the thyroid. OTTO EWALD. Heidelberg. *Z. Krebsforsch.* 15, 85(1915); *Zentr. Biochem. Biophys.* 18, 162(1915).—The colloid which is found in the lymphatic vessels, etc., of the thyroid is not a true secretion of the latter, but is a decompn. product which is not capable of utilization by the organism.

H. S. PAINE.

Relation between suprarenal secretion and vasomotor function of the splanchnic nerve. E. GLEY AND A. QUINQUAND. *Compt. rend.* 162, 86-8(1916); cf. *C. A.* 7, 3518.—The results of expts. upon dog, cat, and rabbit, with and without ligation of the suprarenal veins, are illustrated by 6 tracings. Contrary to the generally accepted idea, the excitation of the splanchnic vasomotor nerve appears to bring into play only a neuromuscular action, and does not produce its effect by the intermediation of a humoral substance (adrenaline).

L. W. RIGGS.

Function of the thyroid-parathyroid apparatus. E. C. KENDALL. Rochester, Minn. *J. Am. Med. Assoc.* 66, 811-3(1916); cf. *C. A.* 9, 1625, 2673.—According to clinical observations in thyroid disturbances the effects are due to a change in the rate of normal function. The stimulating effect of increased thyroid activity is not felt in any particular set of organs or tissues alone, but is active throughout the body. The stimulating action is intracellular. The method of sepn. and purification of the thyroid constituent containing 60% of I suggests that the I is linked through an amino group, and that purification is effected by the entrance of CO_2 into the compd. in place of the amino group. Instead of diiododihydroxyindole proposed in a previous paper, the more recent work points to a structure represented by H_2CO_2 in which one atom of H is replaced by diiodoindole. It seems probable that the production of $(\text{NH}_4)_2\text{CO}_3$ is responsible for the tetany following parathyroidectomy, and that the function of the parathyroid is to convert $(\text{NH}_4)_2\text{CO}_3$ to urea; while the function of the thyroid is to furnish a catalyzer which regulates the rate of deamination. Further elaboration of this hypothesis will not be attempted until after a quant. study of the factors involved.

L. W. RIGGS.

Effect of chloroform on the factors of coagulation. G. R. MINOT. *Am. J. Physiol.* 39, 131-8(1915).— CHCl_3 added to oxalated blood plasma often causes clotting, due apparently to the destruction of antithrombin by the CHCl_3 , allowing the thrombin present to act on the fibrinogen. Antithrombin could not be recovered from CHCl_3 exts. of plasma or serum. Prothrombin is not converted to thrombin by CHCl_3 .

J. F. LYMAN.

Direct evidence of duodenal regurgitation and its influence upon the chemistry and function of the normal human stomach. W. H. SPENCER, G. P. MEYER, M. E. REHFUSS AND P. B. HAWK. Jefferson Med. Coll. *Am. J. Physiol.* 39, 459-79(1916).—The presence of trypsin and bile in the stomach proves that regurgitation from the intestine occurs. Free HCl does not seem to be necessary for the opening of the pylorus. Regurgitation has for its purpose the defense of the small intestine against irritants.

J. F. LYMAN.

Influence of pancreatic extracts on the production of lactic acid in surviving muscles. G. WINFIELD AND F. G. HOPKINS. *Proc. Physiol. Soc.; J. Physiol.* 50, v(1915).—Pancreas ext. added to autolyzing muscle had an inhibiting action on the formation of lactic acid. The responsible factor is stable toward heat. Commercial preps. of pancreatin even when very old contained the factor. Cf. *C. A.* 9, 2927.

H. GIDEON WELLS.

Complement fixation in varicella. J. A. KOLMER. Phila. *J. Immunology* 1, 51-8(1916).—An antibody in the nature of an amboceptor is present in the sera of persons suffering with varicella. This antibody will absorb complement in the presence of an antigen prepared from the cutaneous lesions of this disease. The percentage of positive reactions is small as is also the degree of complement absorption. While immunity principles are in all probability present in the body fluids of persons for years after an attack of varicella, these could not be detected by the complement-fixation tests in this study. All positive reactions were observed during or soon after an attack of the disease and at the time of probable highest concn. of antibodies.

GEO. T. CALDWELL.

Complement fixation in vaccinia and variola. J. A. KOLMER. Philadelphia. *J. Immunology* 1, 59-81(1916).—The sera of rabbits inoculated with cowpox virus yielded positive complement-fixation reactions with salt soln. antigens of cowpox and smallpox viruses in 7 or 8 days after vaccination. The antibody of cowpox virus in the sera of vaccinated animals showed a distinct and close biological relationship to the antigen of variola in complement-fixation expts. Of 13 persons vaccinated with cowpox virus from 7 days to 10 years previously and whose sera yielded negative Wassermann reactions, positive reactions with salt soln. antigens of cowpox virus were observed with 4 or 22%. The serum of one of these 4 persons also reacted positively with a salt soln. antigen of variolous material. The sera of unvaccinated persons reacted negatively with all antigens. Of 17 persons suffering with mild smallpox, the sera of 9 or 60% yielded positive complement-fixation reactions with salt soln. antigens of variolous and cowpox viruses. While the degree of complement absorption was relatively weak in all instances, the reactions were generally stronger with the variolous antigens than with the cowpox antigens. Alcoholic exts. of variolous and cowpox viruses possessed little or no antigenic sensitiveness. These complement-fixation reactions demonstrate the close biological relationship between the antibodies of variola and vaccinia.

GEO. T. CALDWELL.

The fate of various antibodies in the precipitin reaction. F. P. GAY AND RUTH L. STONE. Univ. Calif. *J. Immunology* 1, 83-104(1916).—Previous work has shown that at least certain antibodies can be brought down in the course of a specific precipitin reaction. The method of bringing down antitoxins with the precipitate has been effective in those instances in which the antitoxic serum served as the precipitinogen in the reaction. The authors attempted to reverse the process by producing both antitoxins and precipitins to the diphtheria bacillus in rabbits and horses. The results were negative owing to the fact that precipitins were not produced in these animals. Bacteriolysins and hemolysins when associated either with the precipitinogen serum or with the precipitin serum are not brought down in the formation of the precipitate. Similar negative results were obtained with artificial bacterial agglutinins and hemagglutinins. Expts. on the fate of the fixation antibodies in the precipitin reaction have shown, in general, that when the precipitate is produced by adding serum to its anti-serum the fixation complex is present in the precipitate, but this is not invariable. When bacterial ext. is added to an immune serum the fixation complex seems usually present in the supernatant fluid.

GEO. T. CALDWELL.

Kidney lesions in chronic anaphylaxis. T. H. BOUGHNON. Univ. Ill. Med. School, Chicago. *J. Immunology* 1, 105-16(1916).—Repeated anaphylactic shocks, induced in guinea pigs by injections of egg-white or beef-serum, are able to produce lesions of the kidney that are not produced by acute anaphylaxis nor by the repeated injection

of these proteins in refractory animals. These lesions consist principally of necrosis of tubular epithelium, proliferation of glomerular capillary endothelium and swelling and degeneration of the intima and media of small vessels. Small diffusely scattered areas of round cell infiltration were observed in nearly all cases. The lesions in this series are subacute rather than chronic.

Immunity in tuberculosis. G. B. WEBB. Colorado Springs. *J. Lab. Clin. Med.* 1, 414-28(1916).—A review.

GEO. T. CALDWELL.

Tissue cellular protein poisons. J. G. CUMMING. Berkeley, Calif., AND J. S. CHAMBERS, Ann Arbor. *J. Lab. Clin. Med.* 1, 428-38(1916).—Toxic protein fractions can be prepd. from tissue cells of the exsanguinated organs of multicellular animals. These poisons are not only toxic for heterologous species but also for homologous species. The min. lethal doses (for the guinea pig and the rabbit) of the protein poisons here reported are in proportion to the relative body wts. when given by intraperitoneal injection; when given intravenously they are proportionately 25 times more toxic for the guinea pig than for the rabbit. Tissue cellular protein poisons hasten the clotting of blood from the guinea pig, rabbit and dog *in vivo*. The protein poison prepd. from casein differs from these in that it either retards or prevents entirely the clotting of dog blood. Witte peptone does not prevent the clotting of rabbit blood *in vitro*.

GEO. T. CALDWELL.

Studies in anaphylaxis. R. WEIL. Cornell Med. School, N. Y. *J. Med. Res.* 30, 299-364(1914); cf. *C. A.* 8, 740; 9, 1638. VII. **The relation between antibody content and lethal dose in anaphylaxis.**—When guinea pigs are passively sensitized by means of different amts. of heterologous (rabbit) immune serum, the minimal fatal dose of antigen (horse serum) given intravenously is in an inverse relation to the amt. of the previous sensitizing dose. When the uteri of guinea pigs are compared by Dale's method, it is found that the larger the sensitizing dose of immune serum the smaller is the amt. of antigen required to produce a muscular contraction. The conclusion is drawn that the minimal anaphylactic dose is in an inverse ratio to the degree of sensitization of the guinea pig. In general, the relative amt. of the minimal anaphylactic dose permits of an inference as to the amt. of antibody possessed by the guinea pig. VIII. **The function of circulating antibody and the avidity of cellular antibody.** Circulating antibody protects a sensitized animal to a certain extent from the anaphylactic effect of an intravenous injection of antigen. The degree of protection is not quant. proportional to the amt. of antibody in the circulation but is considerably less than this. The uterine prepn., which is taken to exemplify the condition of all the cells of the body, may be desensitized by the intravenous injection of antigen, whereas the circulating antibody of the same guinea pig remains unsatd., as is evidenced by the fact that the blood effectively sensitizes a normal guinea pig. The conclusion is drawn that the avidity of cellular antibody for antigen is considerably greater than that of circulating antibody. If sensitized guinea pigs are previously given large amts. of antibody intravenously their cells are not desensitized by an amt. of antigen, given subcutaneously, which suffices completely to desensitize the control animals. At the same time their circulating antibodies are satd. to such an extent as to preclude the possibility of passively sensitizing normal guinea pigs with their blood. Circulating antibody protects fixed antibody from antigen, when the latter is introduced by a route permitting of slow absorption. It seems evident that in the usual process of disease this mode of protection must be in some degree effective. IX. **The relation between partial desensitization and the minimal lethal dose in anaphylaxis.** An isolated uterus which has been partially desensitized by the addition of small amts. of antigen fails to respond except upon the administration of very large amts. of antigen. The same condition holds true of the living animal. A guinea pig which has been par-

tially desensitized by the injection of antigen can be killed only by the use of much larger quantities than are required for the unaltered sensitized control animals. The increased dose of antigen necessary to elicit an anaphylactic response is due to an altered condition of the antibody. It is suggested that the presence of antigen depresses the reactivity of the antibody in the cells, necessitating the use of much larger amts. in order to produce a response. Complete desensitization is shown to depend upon the same general process, with the difference that the reactivity of the antibody is entirely abolished by the great excess of antigen. X. The persistence of intracellular antigen as a factor in immunity. When a guinea pig is sensitized by the intraperitoneal injection of a large amt. of the serum of a rabbit immunized against horse serum it becomes possible by Dale's method to det. the persistence of sensitization to horse serum over a period of 15 days. The degree of sensitization gradually diminishes. At the same time there is a gradual development of sensitization toward rabbit serum. Coincidentally, the presence of circulating antibodies towards rabbit serum is demonstrated in the serum by using it passively to sensitize normal guinea pigs. These data are interpreted to indicate that both antigen (rabbit serum) and antibody thereto, coexist for some time in the cells of a guinea pig immunized by large doses of a foreign serum; and that the blood at the same time contains free antibodies. The suggestion is made that the persistence of antigen in the cell is a factor which contributes materially to the resistance of animals sensitized to massive doses of antigen. XI. The share of intracellular antigen in immunity and in desensitization. This section is devoted to a theoretical consideration of the data presented in the preceding sections of this article. XIV. The relation between precipitin and sensitizin. *J. Immunology* 1, 1-18(1916).—The term "anaphylactic antibody" has been replaced here by the word "sensitizin." No distinctions are at present known between the substance responsible for active and that for passive sensitization, so that both are covered by this term. Ppts. produced by a combination of horse serum and of the serum of a rabbit immunized against horse serum induce passive sensitization toward horse serum when injected intraperitoneally into a guinea pig. The same results hold for ppts. produced by cryst. egg albumen and the serum of a rabbit immunized thereto. Marked relative excess or deficiency of either factor in this reaction produces a ppt. which fails to sensitize passively. The sensitizing antibody is not merely adsorbed or carried down mechanically with the ppt. The precipitin is identical with the sensitizin. If an immune serum is heated at 70° for 1½ hr., it loses its pptg. power, while its sensitizing value is but slightly impaired. The admixt. of antigen in excess inhibits pptn. but affects sensitization in much slighter degree. The Na₂CO₃ ext. after heating sensitizes but has no pptg. effect upon antigen. High diln. of the antibody may markedly delay the precipitin reaction while not affecting passive sensitization. The data show that various agencies and conditions which inhibit pptn. may impair sensitization to only a moderate or very slight degree. XV. Equilibrium in precipitation reactions. Equilibrium in combination. *Ibid* 1, 19-34.—When horse serum is mixed in proper proportions with the serum of a rabbit immunized thereto, and the resulting ppt. is removed by centrifugalization, the supernatant fluid is found to contain both antigen and antibody. The same results are obtained with raw egg albumen and the serum of a rabbit immunized thereto. When purified cryst. egg albumen is used as antigen, the results are entirely different. If this antigen is mixed in graded proportions with the serum of a rabbit immunized thereto, and the resulting ppts. are removed by centrifugalization, the supernatant fluid never contains both antigen and antibody. Either one is present alone. It is shown by absorption expts., using cryst. egg albumen, raw egg albumen and their respective antisera as factors, that raw egg albumen contains more than one antigen and that the antiserum thereto correspondingly contains more

than one antibody. It has not been found possible to induce cross-pptn. by mixing the sera of different rabbits immunized against cryst. egg albumen. This succeeds when raw egg albumen is the antigen. Antigen and pptg. antibody do not coexist in the same fluid without undergoing union and pptn. The theory that they do so coexist is based on the use of a mixed antigenic substance such as horse serum, which actually contains numerous antigenic substances. XVI. Equilibrium in precipitation reactions. Dissociation. *Ibid* 1, 35-46.—Ppts. contain both antigen and antibody as shown by the fact that they sensitize both actively and passively. If ppts. are treated with salt soln. in the incubator, the exts. are found to contain a small amt. of antigen but no antibody. If ppts. are extd. with solns. of Na_2CO_3 , antigen is readily demonstrable in the exts. Precipitin cannot be demonstrated but antibody is demonstrable in large amts. by the method of passive sensitization. Extn. with trypsin and with leucocytes yields both precipitin and precipitinogen. While extn. of ppts. yields both components, the procedure may deprive the antibody of its pptg. function. To what factor this change is to be ascribed cannot be positively stated. It is possible that the antigen and the antibody in the ext. are not actually dissociated but are in soln. in combined form. XVII. The coexistence of antigen and antibody in the body. *Ibid* 1, 47-9.—It has been shown that antigen and antibody may coexist in the same fluid in the test-tube in reactive form. It is known that fixed antibody may attack fresh antigen. It is, therefore, quite in accordance with observations on immune reactions in the test-tube to maintain that antigen and antibody may coexist in the blood and in the cells of the living animal and that, even in combination with antigen, the antibody is still capable of reacting with fresh antigen.

GEO. T. CALDWELL.

Hemolysin production by the streptococci. H. W. LYALL. Brooklyn. *J. Med. Res.* 30, 515-32 (1914).—The production of a potent hemolysin in broth cultures is dependent on the nature and proportions of enriching substances, the reaction of the medium and the time of incubation. The hemolytic titer does not afford any absolute criterion of virulence. The hemolysin appears to be closely associated with the bacterial bodies and not to be in soln. It is destroyed by a temp. of 56° for 30 min. It disappears within 48 hrs. at incubator temp. Normal sera of sheep, guinea pig, rabbit, cow and man contain appreciable amts. of antistreptolysin. Salvarsanized sera possess a markedly increased inhibitory power toward the hemolytic action of streptococci. Dextrose inhibits hemolysin production.

GEO. T. CALDWELL.

Influence of febrile conditions on inoculation agglutinins. H. L. TIDY. Brit. Hosp., Netley. *Lancet* 1916, I, 241-2.—After the fifth day of marked pyrexia a positive agglutination reaction to *B. typhosus* is a proof of typhoid fever as reliable for inoculated as for uninoculated persons. The inoculation agglutinins are diminished or entirely removed by febrile conditions. It is possible that they are converted into agglutinoids. In certain cases they may return but usually do not do so. Immunity conferred by inoculation may be affected at the same time as the inoculation agglutinins.

GEO. T. CALDWELL.

Fat intoxication. O. WELTMANN. *Wiener klin. Wochschr.* 27, 971 (1914); *Expt. Sta. Record* 33, 69.—Continued exptl. feeding of fats produced hemolysis and the presence of a lipid-like substance in the blood. As this did not occur with the incorporation of fatty acids, such as from 1 to 2 g. of oleic acid, it is concluded that the mechan. digestion of fats in the intestinal tract produces hemolytically active end products which under certain conditions, such as injury to the intestinal membrane, may pass into the blood.

E. J. C.

Investigation of the specificity of serum reactions after the introduction of different groups into proteins. K. LANDSTEINER AND H. LAMPL. Vienna. *Zentr. Physiol.* 30,

329-30(1915).—The authors produced, by the use of antigens formed by the action of mono-, di- and tri-chloroacetyl, valeryl, anisyl and cinnamoyl chlorides on protein, immune sera that were specific; specificity was more pronounced in some cases than in others. They also immunized with compds. of horse serum and diazo derivs. of aniline, sulfanilic acid, *p*-aminobenzoic acid and atoxyl. The types of immunity were distinct and gave specific precipitin reactions.
F. HULTON.

Renal tests with lactose. W. WECHSELMANN. Berlin. *Berl. klin. Wochschr.* 53, 84-5(1916).—Since Selager introduced the intravenous injection of lactose as a test of the kidney efficiency, it has been tried by a large number of people, most of whom found it objectionable because of the violent reaction which follows its use. Such symptoms as chills, fever, and vomiting ensued. W. finds that this is the result of the lactose being infected. If the sugar is made absolutely sterile all after-reactions are eliminated. Such a sterile prepn. can be bought on the market in ampoules containing 2 g. each. The contents of an ampoule are mixed with 20 cc. of freshly distd. H₂O and injected intravenously.
JULIAN H. LEWIS.

The natural resistance of the pigeon to the pneumococcus. PRESTON KYGA. Univ. Chicago. *J. Infect. Dis.* 18, 277-92(1916).—In the pigeon, a species insusceptible to the pneumococcus, the infecting organisms are rapidly withdrawn from the general blood stream and localized in the liver and the spleen. In both these organs the ultimate localization of the pneumococcus is within a type of fixed phagocyte (the hemophage) common to both organs, and having for its normal function the destruction of red corpuscles. This phagocytic destruction of the pneumococci by hemaphages is so extensive and so rapid as actually to constitute an important, if not indeed the determining, factor in the establishment of this instance of natural immunity.
JULIAN H. LEWIS.

Supposed acid intoxication of diabetic comas. E. P. POULTON. *Proc. Physiol. Soc.; J. Physiol.* 50, 1(1915).—H⁺ ion concn. in 8 cases of diabetes mellitus, detd. by the oxyhemoglobin dissociation curve of the blood, is not sufficient to account for diabetic coma; hence acid intoxication should not be applied to explain the pathology of the condition.
J. F. LYMAN.

Experimental production of hemolytic splenopathies and myelopathies by means of specific antisera. A. BONOME. *Atti r. ist. Veneto* 73, II, 195-259(1913).—An anatomical-pathological study. Intravenous injections of hemolytic sera in dogs and rabbits produce changes in hemo-lymphoid organs, liver and kidneys, comparable to the lesions in hemolytic spleno-myelopathies in man.
D. I. MACHT.

Lymphocytosis and injury to the eye. FRANK AND HECK. *Arch. Ophth.* 89, No. 3(1915); *Zentr. Biochem. Biophys.* 18, 349(1915).—Lymphocytosis, which ensues in a relatively large number of long-standing cases of injury to the eye, is not considered as an anaphylactic manifestation on the part of the blood.
H. S. PAINE.

Origin of long-sightedness and senile cataract. F. SCHANZ. Dresden. *Arch. Ophth.* 89, No. 3(1915); *Zentr. Biochem. Biophys.* 18, 330(1915).—S. emphasizes the significance of light in causing a modification of the structure of the proteins (transformation of readily sol. into more difficultly sol. proteins). He discusses his own earlier work and that of Chaluppecky.
H. S. PAINE.

Anaphylaxis and the eye. M. ZADE. Frankfurt a/M. *Arch. Ophth.* 89, 459(1915); *Zentr. Biochem. Biophys.* 18, 349(1915).—Anaphylactic cornea expts. with guinea pigs showed that these animals may be rendered anaphylactic by intracorneal sensitization and intraperitoneal re-injection. Single intracorneal injection of horse serum produced more or less pronounced corneitis; secondary corneitis was also observed, while in many cases the eye was free from irritation on the day following the

injection. Egg white (1:3 and 1:10) was tolerated in the cornea of the guinea pig without irritation. Local re-injection after intracorneal sensitization did not produce anaphylaxis. Subcutaneous sensitization and ocular re-injection with egg white did not cause local reaction; secondary corneitis was sometimes observed when pure horse serum and toxin-antitoxin mixt. were employed. This was a severe, diffuse, parenchymatous corneitis with formation of new blood vessels which cleared almost completely after several weeks; it was probably of anaphylactic nature. A poison (artificial "anaphylatoxin") with severe tissue-imparting action toward the rabbit cornea was prepd. by digestion of active guinea-pig serum with starch. H. S. PAINE.

Cholesterol sclerosis. A. V. KNACK. Mannheim and Hamburg-Barmbeck. *Arch. Path. Anat.* 220, 36(1915); *Zentr. Biochem. Biophys.* 18, 164(1915).—The human suprarenal cortex shows gradual degenerative changes in atherosclerotic affection (histological analogy to sclerosis due to feeding) which are apparently dependent on the content of fatty substances, this content being unusually high in atherosclerosis. The cells of the *zona fasciculata* show the greatest change. Such degeneration processes are also existent in non-atherosclerotic, especially toxic-infectious, affections, but are likewise dependent on the presence of fatty substances. A more pronounced degree of sclerosis of the aorta was observed with rabbits in the case of egg and milk feeding than in the case of exclusive cholesterol feeding. Modification of the suprarenals in the case of increased introduction of cholesterol is explained by coincident impairment of the cortex cells so that these are no longer capable of eliminating the fatty substances; cortex cells are destroyed and are replaced by an accumulation of cholesterol. H. S. PAINE.

Mechanism of rabic immunization. II, III. CLAUDIO FERMI. Univ. Sassari. *Centr. Bakt. Parasitenk., Abt. I Orig.* 76, 349-55(1915); *Zentr. Biochem. Biophys.* 18, 348(1915). II. Immunizing power of rabic saliva and salivary glands, i. e., rabic virus isolated from nerve substance.—The rabic virus of the salivary gland has no immunizing power. III. Immunizing power of the rabic nerve substance of animals (chickens, ducks) the normal nerve substance of which is free from immunizing power.—The nucleoprotein of the entire cerebral substance of normal animals has lyssicidal power; this is not true, however, of the nucleoprotein of the white and gray substance taken separately. The nucleoprotein of the yolk and testicles has no lyssicidal action. H. S. PAINE.

Abderhalden reaction. PARODI AND VIDONI. Genoa. *Sperimentale* 68, 427-40; *Zentr. Biochem. Biophys.* 18, 190(1915).—P. and V. tested the sera of patients suffering from mental affections with respect to placenta and thyroid. Varying results were obtained with the sera of non-pregnant individuals, even when the Abderhalden technic was rigorously followed. In many cases the sera gave a positive ninhydrin reaction without concurrent action of substances containing protein; in other cases the sera of non-pregnant individuals gave at times positive results with placenta ext. The Abderhalden reaction is apparently not strictly specific in indicating pregnancy. The behavior of sera toward thyroid ext. also varied and was independent of thyroid protein. The reaction is capable of disclosing interesting properties of sera, but the difficulty of the technic is a great hindrance to its ready application. It is worthy of note that the reaction with placenta ext. was positive in the case of certain disorders of the sexual organs and that a strong positive reaction toward thyroid ext. was obtained in the case of an epileptic suffering from myxedema. H. S. PAINE.

Immunization toward dysentery with toxin-antitoxin mixtures. BR. BUSSON. Vienna. *Wiener klin. Woch.* 1915, 853; *Zentr. Biochem. Biophys.* 18, 353(1915).—Rabbits may be effectively immunized toward Shiga-Kruse dysentery poison with free toxin and also with under-neutralized toxin-antitoxin mixts. H. S. PAINE.

Action of tumor autolysates in the treatment of malignant neoplasms. RICHARD BAUER, ROBERT LATZEL AND EMIL WESSELY. Vienna. *Z. klin. Med.* 81, 420-37 (1915); *Zentr. Biochem. Biophys.* 18, 310(1915).—The authors give a brief survey of the literature and describe in detail the technic of prepg. autolysates, especially from operated mammary carcinomas; the results of intravenous injection of autolysate in cases of inoperable carcinoma and sarcoma are also discussed. No anaphylaxis was observed in the symptom complex of cases with fatal issue subsequent to autolysate injection. The metabolism of a series of carcinoma patients was studied before and during autolysate treatment with reference to introduction and elimination of N; the autolysates caused increased albumin elimination and often negative N balance.

H. S. PAINE.

Aminolytic enzyme in the stomach contents in carcinoma. J. HALPERN. Heidelberg. *Mitt. Grenzgeb.* 28, 709-17(1915); *Zentr. Biochem. Biophys.* 18, 342(1915).—An enzyme which produced cleavage of monoamino acids with formation of NH_3 and formic acid was detected in the gastric juice of patients suffering from gastric carcinoma; this enzyme does not occur in normal gastric juice and is probably a secretion product of the cancer cells. It is not certain whether the enzyme occurs in other affections.

H. S. PAINE.

Blood obtained by puncture of vein best for serodiagnosis. M. PARVU. *Arch. mal. coeur* 8, No. 12(1915); *J. Am. Med. Assoc.* 66, 775.—P.'s extensive research has shown that the antibody content is always highest in the blood obtained by puncture of a vein, positive results in testing for antibodies being obtained by such puncture when blood from the ear or finger is constantly negative. Serum in venous blood contains the max. of antibodies, alexins and hemolysins. The blood must be allowed to clot naturally. The 10 or 12 hrs. which this requires allows time for the leucocytes to yield up to the serum all their lysins and antibodies. Blood should never be centrifuged or defibrinated for serodiagnosis; otherwise the leucocytes keep alive and retain the antibodies. This is easily shown by testing the serum for antibodies, alexins and lysins at different stages of the coagulation process.

L. W. RIGGS.

Clinical significance of the diazo reaction and the urochromogen reaction in lung tuberculosis. O. SCHUMM AND E. QUERNER. Hamburg, Ependorf. *Mitt. Hamburg Syattskrankenanstalt.* 14, 133-55(1913).—Neither reaction is of great value in the diagnosis of lung tuberculosis.

C. J. WEST.

The coagulation of *Bacillus enteritidis* an aid in the diagnosis of typhoid fever. G. SEIFFERT. *Münch. med. Wochschr.* 63, 1753-4(1916).—In cases vaccinated against typhoid fever or against typhoid fever and cholera combined, the serum agglutinates typhoid bacilli, making this of but little value for the diagnosis of an existing typhoid. Serum of such cases does not agglutinate *B. enteritidis* and serum of persons having had typhoid fever several years previously only relatively rarely. During an attack of typhoid fever the serum agglutinated *B. enteritidis* and typhoid bacilli in 45.5% of the cases. The titer of agglutination of *B. enteritidis* is 1:50-1:200. This fact may aid in the diagnosis of typhoid fever.

S. AMBERG.

H. PHARMACOLOGY.

ALFRED N. RICHARDS.

Exanthemata due to mercury mistaken for effects of salvarsan. W. WECHSEL-MANN. *Münch. med. Wochschr.* 62, 1638-40(1915).—In cases treated simultaneously with Hg and salvarsan great care must be exercised in attributing a skin affection offhand to salvarsan, since skin eruptions due to the administration of Hg are not infrequent. The differential diagnosis is considered; it is particularly to be noted that salvarsan symptoms do not lead to peeling of the skin, to formation of vesicles or to fever

of any duration. In a case having undergone a combined inunction and salvarsan treatment with peeling of the skin, the urine showed the presence of Hg more than a month after cessation of treatment while As could not be found. It may be possible that salvarsan aids in the production of a Hg exanthem. S. AMBERG.

The resistance of *Leptodactylus ocellatus* (Argentine frog) toward curare, and some points on the general physiology of muscles. M. CAMIS. Univ. La Plata. *Arch. farm. sper.* 21, 3-48(1916).—This animal presents a remarkable resistance to curare, paralysis resulting only after doses 10-20 times greater than those required for the same response in the European frog. Doses of 0.005-0.01 g. do not diminish the excitability of the gastrocnemius muscle in 1 hr. The same resistance was noted toward nicotine, but not toward veratrine. The paralysis produced by large doses of curare is not accompanied by abolition of nervous excitability, and terminates generally with the death of the animal. The analytical method, which is based on the detn. of time of stimulation, permits the recognition in the nerve region of the sartorius of two irritable substances. The data suggest the possibility that the special behavior of *Leptodactylus* depends on the absence from its muscles of the receptive substances for curare. This confirms the doctrine of the receptive or β -substance. A. W. DOX.

Vaso-constrictive actions of serum on the coronary vessels of the mammalian heart. H. YANAGAWA. London. *J. Pharmacol.* 8, 89-100(1916).—The previous work of Cushny and Gunn (*C. A.* 8, 175) was extended to the study of other proteins and colloids, and also to det. which constituents of serum are responsible for vasoconstriction in the coronary arteries of perfused hearts of cats and rabbits. Cat and horse serum produced coronary constriction with reduction in rate and force of the heart-beat. 5% soln. starch and dextrin containing Ringer salts, 1% glutin and 4% gum arabic first dialyzed and then modified with Ringer salts had no effect. Some of these solns. were very viscous, indicating that increased viscosity of the perfusion fluid has little influence on the heart and vessels. 1% peptone (Witte) and a satd. soln. of agar-agar previously dialyzed and then treated with Ringer salts, dilated the coronary vessels and increased the force and beat of the heart. Dialyzed horse serum constricts the vessels so that the globulin portion is inefficient. The constrictor efficiency of serum and egg-white protein is lost if they have been pptd. by salts or EtOH, but the proteins which are not pptd. by boiling and those sepd. by Hardy and Gardner's method with acetone-ether continue to act. The effect of these proteins on coronary flow is similar to that of dil. alkali, but when alkali is used, the change in H^+ concn. which is necessary to cause this action is far greater than that developed when serum is added to Ringer soln. Therefore the action cannot be explained by the serum changing the alkalinity of the perfusion fluid. It is also pointed out that considerable difficulty has been met in distinguishing the action of serum as such from that of epinephrine by perfusion through the frog limbs, or the mammalian organs, but there can be no such difficulty in the case of the rabbit heart, for here serum causes vaso-constriction, while epinephrine almost invariably causes pronounced vaso-dilatation.

P. J. HANZLIK.

Quinine and atophan in inflammation of frog mesentery. YASUO IKEDA. Cambridge, Eng. *J. Pharmacol.* 8, 101-7(1916).—Previous investigators have shown that both drugs possess antiphlogistic actions. I.'s object was to ascertain whether a combination of the two drugs would give a synergistic action in the same direction. The method of Cohnheim (*Arch. path. Anat.* 40), which consists of the microscopic study of the migratory power of leucocytes in the vessels of the frog mesentery, was used. Quinine-HCl has no effect on migration in doses of 1.25 mg., or less; the effective dose begins at 1.56 mg. for a frog of 15 g.; up to 2.5 mg. no permanent inhibition was obtained, but in some animals the circulation was severely affected. The effective dose of atophan ranges

from 6.25 to 12.5 mg. per frog; 75 mg. completely inhibited the migration without depressing the circulation. When quinine and atophan are combined in such small doses as $\frac{1}{3}$ of the max. ineffective dose, they act powerfully, inhibiting the migration of leucocytes more than much larger doses of quinine alone, suggesting in this respect a synergism between the two drugs.

P. J. HANZLIK.

A study of urinary nitrogen and sulfur partition in a case of rheumatoid arthritis treated with intravenous injections of radium salts. JACOB ROSENBLOOM. *Am. J. Med. Sci.* 149, 718-22(1915).—The intravenous injection of 100 micrograms of Ra element produced an increase in the amt. of N excreted in the urine, but had no constant effect on the percentage excretion of urea N, ammonia N, uric acid, amino acid N, creatinine N and undetd. N was observed. It caused a marked increase in the amt. of total urinary S and of neutral S. This effect on the N and S metabolism lasted for about 3 days following the injection.

TULA LAKE HARKEY.

Mode of action and use of emetine in entamebiasis. RANDOLPH LYONS. *Am. J. Med. Sci.* 150, 97-109(1915).—Emetine exerts its specific effects only on those entamebas within reach of the circulation. The method of its elimination from the body is not definitely known. Subcutaneously and locally, emetine has been shown to be practically specific in pyorrhea alveolaris.

TULA LAKE HARKEY.

Removal by caffeine of some digitalis arrhythmias. WILFRED M. BARTON. *Am. J. Med. Sci.* 150, 352-8(1915).—All irregularities of the heart beat which are brought about by digitalis tend to be removed by caffeine. The action appears to be due to the increase in irritability of the conduction system produced by the caffeine, which antagonizes and finally overcomes the depressing effects of digitalis upon the auriculo-ventricular bundle.

TULA LAKE HARKEY.

The influence of cocaine on the stimulation of the psychomotor region and the cortex of the cerebellum. G. BIKELIS AND L. ZBYSZWESKI. *Lemberg. Zentr. Physiol.* 29, 3-4(1914).—The authors stimulated parts of the cerebellum, covered with filter paper wet with a 5% and a 10% cocaine soln. and found that the cocaine caused no depression or only a slight depression of the threshold of stimulation. This is just the opposite of its effect on the cerebrum.

F. HULTON.

Influence of oil of chenopodium on intestinal contractility. W. SALANT AND C. W. MITCHELL. *Bur. Chemistry. Am. J. Physiol.* 39, 37-53(1915).—Oil of chenopodium (1 to 5000 and 1 to 10,000 solns.) diminishes frequency as well as force of contractions in isolated intestine of rabbits. With intestine from carnivorous animals there is usually a rise of tone followed by a steady decline, rhythmic contractions finally ceasing. Recovery occurred in Locke soln. Relatively large intravenous doses of oil of chenopodium are required to inhibit peristalsis in intact rabbits, due perhaps to the presence of substances antagonistic to the drug. Caffeine, BaCl_2 and pilocarpine have a true antagonistic effect. Oil of chenopodium acts on the nerve endings as well as on muscular structures.

J. F. LYMAN.

Influence of heavy metals on the isolated intestine. W. SALANT AND C. W. MITCHELL. *Bur. Chem. Am. J. Physiol.* 39, 355-74(1916).—Zn malate solns. (0.0001 N) caused depression of tonus and decrease of amplitude within 3 mins. The same concn. of Ni acetate sometimes caused primary stimulation usually followed by recovery and stimulation. Zn is more toxic than Ni as shown by the greater injury produced and by the subsequent response to BaCl_2 and pilocarpine.

J. F. LYMAN.

Effect of nicotine upon the reflex action of some cutaneous sense organs in the frog. IRENE HOWAT. *Univ. Kansas. Am. J. Physiol.* 39, 447-54(1916).—Nicotine injected into the dorsal lymph space of frogs in small doses caused a loss of skin reflexes,

forced breathing, fibrillar twitching and constriction of the pupils. In large doses it caused an inhibition of respiratory movements, tetanus contraction of the front legs, and sometimes a slight stiffening of the whole body, followed by relaxation and loss of muscle tonus. Continued doses resulted in the development of tolerance, increased irritability of skin reflexes, loss of wt. and discoloration of the skin. The toxic dose varied from 6 to 27 minims of 1% soln. per 10 g. frog. J. F. LYMAN.

Action of barium chloride on the vascular system. Antagonistic action of nicotine and curare. E. P. CATHCART AND G. H. CLARK. Glasgow Univ. *J. Physiol.* 50, 119-27(1915).—BaCl₂ in decapitated rabbits produces a marked rise of blood pressure which is inhibited by nicotine and restored by a subsequent injection of curare. The antagonistic action of nicotine and curare observed by Langley (*C. A.* 8, 3078) for skeletal muscle thus holds good for the involuntary muscle of the arterioles. BaCl₂ probably does not act directly on the contractile substance. BaCl₂ and adrenaline do not act on identical parts of the muscle. J. F. LYMAN.

Action of lead on the cardio-vascular apparatus. P. D. SICCARDI. *Atti r. ist. Veneto* 73, II, 323-86(1913).—*A priori* changes in the cardio-vascular apparatus may explain most of the manifestations of saturnism or lead poisoning. Vasomotor crises might account for lead colic; vascular changes (hypertension, sclerosis, and atheroma) may produce chronic nephritis; disturbances in cerebral circulation may explain encephalitis. S. studied extensively the effect on blood vessels, effect on blood pressure, and effect on the heart. Vascular effect was studied on isolated vessels *in vitro* in Ruiger soln. and *in situ* by perfusion of various parts. In all excized surviving arteries including the coronary, lead always produced a progressive and marked vaso-constriction, proportional to the dose of the drug (neutral Pb acetate). In perfusion experiments, constriction was everywhere produced, but the renal and hepatic arteries were contracted more than the musculo-cutaneous vessels. Washing the vessels *in vitro* and perfusion treatment arrest but do not overcome the effect of the poison except after very small doses of lead which acted only a few minutes. Washing with minute doses of atropine in physiol. saline quickly relaxes the lead spasm. The constriction by Pb and relaxation by atropine are probably due to direct action on smooth muscle of the arteries. The Pb soon becomes fixed in the endothelium and muscle cells, as proved by the microscope, hence the persistence of the effect. The effect on blood pressure (in dogs) varies with the quantity of Pb and rapidity of injection. Very small doses produce a slight rise in pressure; larger doses produce depression. The greater the velocity of injection, the greater is the fall in pressure. *Effect on the heart:* Very small doses diminish cardiac activity; larger doses produce stand-still in diastole. By washing, the heart can be revived after minimal doses, but not after larger ones. Even minimal doses permanently weaken the myocardium. This explains the fall in blood pressure. The weakening of the heart is not explained entirely by interference with coronary circulation. It is observed also after atropinization. Adrenaline revives the heart. The effect on blood pressure is not due to direct action on the vagus, depressor or vasomotor center. All of the circulatory phenomena are due primarily to the affinity of Pb for the smooth muscle of the arteriæ and the muscle fibers of the heart.

D. L. MACHT.

Anaphylaxis in ophthalmology. RADOS. *Arch. Ophth.* 89, No. 3(1915); *Zentr. Biochem. Biophys.* 18, 349(1915).—This is essentially a polemic against v. Szily and Arisawa (*C. A.* 8, 173, 2573). H. S. PAINE.

Pathology of the blood in chronic lead poisoning. SCHNITZER. Offenbach a/M. *Deut. Arch. klin. Med.* 117, 127-55(1915); *Zentr. Biochem. Biophys.* 18, 186(1915).—Pb causes impairment of both the blood corpuscles and bone marrow; sp. injury

of the latter is produced and this injury appears to be proportional to the amt. of Pb which is introduced. The effect of Pb poisoning extends even to the leucoblastic tissue.

H. S. PAINE.

Influence of hypertonic solutions on blood pressure. KARL RETZLAFF. Berlin. *Z. exp. Path.* 17, 192-9(1915); *Zentr. Biochem. Biophys.* 18, 336-7(1915); cf. *C. A.* 10, 213.—R. injected 3 cc. of strongly hypertonic solns. of NaCl and other Na salts (in addition to K, Ca and Mg salts) into rabbits which had been subjected to venesection. An amt. of hypertonic salt soln. equal to only a relatively small proportion of the blood thus removed was sufficient to restore blood pressure to approx. its original value. Perfusion expts. with the frog aorta on the one hand and vol. measurements of the cat heart with simultaneous blood pressure measurement (in order to test the influence of hypertonic salt solns. on the heart) on the other hand showed that the observed increase in blood pressure is due to cardiac action.

H. S. PAINE.

Action of intraperitoneally injected epinephrine. D. LAPPONI. Rome. *Gazz. osped.* 34, 693; *Zentr. Biochem. Biophys.* 18, 163-4(1915).—Numerous expts. with rabbits and dogs showed that intraperitoneal injection of 0.0005-0.005 g. epinephrine causes an increase in blood pressure which persists for more than 1 hr.; this effect was particularly pronounced in the case of dogs in which blood pressure had been diminished by previous blood-letting. Intraperitoneal injections of epinephrine which were repeated daily in increasing amts. (0.5-5.0 mg.) were well tolerated by the animals, even when they were continued for several mos. (83 injections). Necrosis did not occur and calcification with aneurysmal dilatation (such as is often observed in the aorta of rabbits which have received intravenous injections of epinephrine) was not observed.

H. S. PAINE.

Influence of bile acids on heart action. EDMUND NOBEL. Vienna. *Z. exp. Med.* 4, 286-301(1915); *Zentr. Biochem. Biophys.* 18, 182(1915).—In spite of extreme impairment of the contractility of the cardiac muscle after injection of bile and large amts. of the salts of bile acids conduction of stimuli remained practically normal until the death of the animals (dogs).

H. S. PAINE.

Strontium salicylate. M. A. BLANKENHORN. Cleveland. *J. Am. Med. Assoc.* 66, 331(1916).—Expts. on 20 patients at the Lakeside Hospital showed Sr salicylate to have the same av. toxic dose as Na salicylate, producing the same gastric symptoms, and to be in no way superior to other salicylates. Owing to its sparing soly. it is less convenient to administer.

L. W. RIGGS.

Strontium salicylate versus sodium salicylate. H. A. HARE. Phila. *J. Am. Med. Assoc.* 66, 757-8(1916).—H. criticizes Blankenhorn's statements (preceding abstract) and points out the superiority of the Sr compd. (cf. following abstract).

L. W. RIGGS.

Strontium salicylate versus sodium salicylate. TORALD SOLLMANN. Cleveland. *J. Am. Med. Assoc.* 66, 758(1916).—Reply to Hare (cf. preceding abstract).

L. W. RIGGS.

Therapeutic value of the hypophosphites. W. MCK. MARRIOTT. Baltimore. *J. Am. Med. Assoc.* 66, 486-8(1916).—A history is given of the previous work with hypophosphites, 17 references to literature being included. M. has carried out a series of expts. to det. whether or not hypophosphites are utilized in the body. By standard metabolism methods with 4 men it was proved that from 79 to 91.5%, av. 86%, of the intake of NaH_2PO_2 was eliminated in the urine; cf. Forbes, *et al.*, *C. A.* 9, 1072. M. summarizes as follows: "There is no reliable evidence that hypophosphites exert a physiologic effect; it has not been demonstrated that they influence any patho-

logic process; they are not foods. If they are of any use that use has not been discovered."

L. W. RIGGS.

Alliaceous odor produced by iron cacodylate. D. W. MONTGOMERY. San Francisco. *J. Am. Med. Assoc.* 66, 491-2(1916).—When given by the mouth or hypodermically the cacodylates may taint the breath, skin and urine with a strong garlicky odor. M. suggests a method by which the drug may be split in the body so as to yield cacodyl.

L. W. RIGGS.

Experiences with the Kiutsi-Malone urinary test for pregnancy. I. S. CUTTER AND MAX MORSE. Univ. Nebraska. *J. Am. Med. Assoc.* 66, 559-60(1916).—The method of Malone (cf. *J. Am. Med. Assoc.* 64, 1651) was followed throughout. In 24 cases known to be pregnant, 17 gave definitely positive results. Of 5 non-pregnant controls, 4 gave negative reactions. Out of 11 males one gave a positive reaction. The authors point out various theoretical objections to the method and conclude that the test as at present conducted cannot be safely depended upon as a diagnosis of pregnancy, owing to the nonspecificity of the reaction and the frequency of errors.

L. W. RIGGS.

Systemic poisoning with bismuth. W. H. HIGGINS. Richmond Med. Coll., Va. *J. Am. Med. Assoc.* 66, 648-50(1916).—The history of a case of Bi poisoning and a report of a post mortem by Mayer and Baehr of a similar case are given. As the literature records 65 cases of Bi poisoning with 24 fatalities, greater care should be taken in its use.

L. W. RIGGS.

Action of digitalis on peripheral blood vessels. I. V. GOLOVINSKII. *Russ. Vrach.* 14, No. 30(1916); *J. Am. Med. Assoc.* 66, 850.—Digipuratum administered by the method of Kravkov (cf. *C. A.* 8, 2756), or that of Fröhlich (cf. *C. A.* 9, 1511) in doses that may have a therapeutic action does not affect the lumen of the peripheral vessels of the regions examd., while toxic doses cause dilatation. The increased blood pressure from digitalis is thus due to increased cardiac activity.

L. W. RIGGS.

Elimination of picric acid in urine. M. MURAT AND J. DURAND. *J. pharm. chim.* 13, 18-23(1916).—M. and D. studied the effect of self-ingestion of 0.20, 0.50 and 1 g. of picric acid, examg. the total urine collected in 24 hrs. Nine tests for picric acid were employed (cf. *C. A.* 9, 3268; 10, 69, 621), including the pink color test with NaNO_2 , $\beta\text{-C}_{10}\text{H}_7\text{OH}$ and Et_2O , formation of a rose-colored ring with tartaric acid and FeSO_4 , etc. The following conclusions are reached: (1) Picric acid is little toxic. Doses of 1 g. or less are very well supported. With 1 g. a slight fatigue was felt, but the temp. remained normal and no special functional, intestinal, gastric or hepatic reaction was observed. (2) The dark brown color of urine after ingestion of picric acid is not characteristic, as it is also found frequently in true icterus. (3) Elimination begins towards the 6th hr. and proceeds regularly during the following days. With 0.2, 0.5 and 1 g., it lasts, resp., to the 4th, 6th and 12th days. At these limits the more delicate tests are still sensitive, e. g., the rose-red ring. (4) The minimum dose necessary to produce the false icterus seems to be 0.2 g. An icterus caused by such a dose is easily detected, especially if the dose is repeated. (5) In the cases of true icterus, all preceding tests are negative. Of 100 cases examd., only 2 showed picric acid. Wool is turned maroon or dirty green and never gives the isopurpurate test. (6) Picric acid may be identified by the tests indicated, even if 8 days have elapsed after suspected ingestion.

S. WALDBOTT.

The history of structural chemistry and of its association with scientific pharmacology. GORDON SHARP. Edinburgh. *Pharm. J.* 95, 756-7(1915).—The contributions by "the Briton and the Teuton" are recorded; the fundamental work of Crum, Brown and Fraser (1867) is emphasized.

S. WALDBOTT.

Further studies in nicotine tolerance. CHARLES W. EDMUNDS AND MAURICE I. SMITH. Ann Arbor, Mich. *J. Lab. Clin. Med.* 1, 315-20(1916).—The conclusions are that the livers of all dogs possess some power to destroy nicotine and that the destroying agent is probably an enzyme. It is possible that this enzyme may be increased in quantity by the const. use of the alkaloid but these expts. do not furnish any support for this theory. The main difficulty appears to be that under normal conditions the destroying power of different livers varies so much in strength that it is almost impossible to state that it has been increased by treatment. H. G. W.

Hexamethyleneamine as a urate solvent and diuretic, and its effect on the reaction of urine. PAUL J. HANZLIK. Cleveland, Ohio. *J. Lab. Clin. Med.* 1, 321-32(1916).—A résumé is given of the chemistry and the behavior of various solvents toward uric acid and urates; very remote possibilities are indicated of chances of success of so-called urate solvents under conditions of the body. Urate or uric acid soly. is a matter which is concerned largely with the degree of reaction (H-ion concn.) and the concn. of fluids. There is no available evidence in the literature to show that $(\text{CH}_2)_6\text{N}_4$ can influence these favorably. Recent and reliable evidence shows definitely that $(\text{CH}_2)_6\text{N}_4$ *per se* in small quantities, or therapeutic doses, imparts to urine no demonstrable urate solvent qualities. Slight and practically negligible uric acid solvent effects are imparted to urine by excessive doses of $(\text{CH}_2)_6\text{N}_4$ and in this, the effects of the common alk. diuretics are pharmacologically and economically superior. There is no evidence that $(\text{CH}_2)_6\text{N}_4$ can dissolve urate calculi. H. G. W.

The action of choline on the isolated mammalian heart and its antagonistic action toward adrenaline. G. CREVOLTO AND A. SACCHETTO. Univ. Padoa. *Atti ist. Veneto* 74, 315-7(1915).—The expts. were done in order to det. the action of choline on the isolated mammalian heart and to interpret the antagonistic action of adrenaline. Isolated rabbit hearts circulated with Ringer-Locke soln. according to Langendorff's method were used. The choline was introduced with a Pravaz syringe. The minimal dose of choline necessary to stop the heart permanently is 0.02 g. per kg. Non-toxic doses produce variable effects depending on the amt. used but always produce a gradual decrease in the amplitude of the cardiac excursions, decrease their frequency and cause a slight dilatation of the ventricle. The action of choline is almost completely lacking if the animal was previously atropinized. When adrenaline is injected with choline the result is somewhat variable. If the dose of choline is strong in comparison with the adrenaline the result differs from that obtained with choline alone in that the dilatation of the ventricular cavity is much greater and more persistent. However, by using the proper proportions of both, the effect of the adrenaline can be almost completely compensated. If a strong dose of choline is injected and followed with adrenaline the effects of the former are observed but the return to normal is quicker. The antagonism of the 2 compds. is thought to be purely physiological and is independent of any chem. reaction that they may undergo *in vitro*.

E. J. WITZEMANN.

Physical properties of dental cements. PAUL PORTSCHKE. Milford, Del. *J. Ind. Eng. Chem.* 8, 302-9(1916); cf. *C. A.* 9, 3289.—“The object of this paper is to present a method for detg. the crushing strength of dental cements; a study of various factors relating thereto; the results obtained on 40 commercial dental cements, representing the silicate, Zn-oxyphosphate, and Cu types; and finally the utility of the app. described in this paper, for the study of the various properties of dental cements is discussed.” The following summary is given: “(1) In order to establish the fitness of a dental cement, it is necessary to consider, individually and collectively, its various physical, physiological and chem. properties. The compn. of a dental cement has no definite relation to its ultimate properties, nor can *a priori* conclusions be drawn with

reference to the effect of a given constituent in a dental cement. This must be arrived at experimentally. (2) A method for detg. the crushing strength of dental cements is described in detail. The conditions under which the tests are made have been standardized so as to conform, as nearly as possible, to mouth conditions. (3) Crushing strength is of fundamental importance in establishing the relative value of commercial dental cements with respect to their ability to resist masticatory pressure. Tests conducted under saliva have an added significance, in that the effect of the saliva is incidentally detd. (4) Forty commercial dental cements were tested and found to vary considerably in crushing strengths. Retrogression in strength under saliva occurred in a large % of the cements tested. There is no relation between germicidal efficiency and resistance to saliva in the case of the Cu cements. Those showing retrogression in strength in saliva may show either high or low germicidal efficiency. (5) Several properties of dental cements, of importance in applied dentistry, may be studied with the aid of the app. described in this paper." Future papers are promised.

I. ZOÖLOGY.

R. A. GORTNER.

A study of the relation of the chemical composition of hen eggs to the vitality of the young chick. L. J. CROSS. Cornell Univ. *Thesis* 1912, 16 pp.; *Expt. Sta. Record* 32, 86-70.—C. attempted to det. the relation of the vitality of the chick to the chem. compn. of the egg, and to control the compn. of the egg. The results are summarized as follows: The work on the coloring of the parts of the eggs by feeding dyes to the hen indicates that the fat found in the albumen region of the incubated egg is derived not wholly from the yolk, but from another source, the albumen itself. The % of fat in the yolk of the weak chick is in some cases less and sometimes more than in the yolk of the strong chick. The weak chick is equally as rich in P as the strong chick. The P content of the egg varies but little. There is no increase in the P content of the egg when the hen is fed inorg. P. Hens on range do not produce eggs different in compn. from those in the barnyard. There is variation in the eggs of different hens in the content of protein and in the content of fat, but the eggs produced by each individual are quite const. in compn. The sum of the % of fat and of protein in eggs varies but little. In feeding a ration high in fat, or a ration high in protein, there is no material change in the characteristics of the hen as regards the amt. of fat and protein in the egg. There seems to be no relation between the protein or fat content of the egg as regards its hatching power or the vigor of the young chick. E. J. C.

Resting metabolism of insects and its dependence upon temperature. TAGG ELLINGER. Copenhagen. *Int. Z. phys.-chem. Biol.* 2, 85-94(1915); *Zentr. Biochem. Biophys.* 18, 312(1915).—E. studied the resting metabolism of *Culex annulatus*. Earlier detns. of the respiration of the insect are very strongly influenced by the increased metabolism due to muscular work. The temp.-raising metabolism of *Culex* is identical with that found by Krogh for various cold-blooded vertebrates. E. concludes that the curve observed in the case of vertebrates and invertebrates is generally applicable to cold-blooded animals.

H. S. PAINE.

Toxins of the Araigneae and particularly of the Tégénariae. R. LEVY. *Compt. rend.* 162, 83-6(1916); cf. *C. A.* 6, 1935; 7, 650.—In addition to its hemolytic properties arachnolysin produces a general intoxication which may be fatal. This toxin was recovered from the eggs of several species of *Epeiridae* and from *Theridion lineatum*. The eggs of *Tégénaria atrica* yield a toxin and an hemolysin quite different from arachnolysin. The latter can hemolyze the corpuscles of the drake and hen, which are not acted upon by the toxin of the former. A maceration of the eggs of *T. atrica* in physio-

logic saline containing 10 eggs per cc., is inactivated by standing 10 min. in a drying oven at 60-62°, while arachnolysin requires 6-8 hrs. at 62°. Both toxins are inactivated by the addition of HCl. Inactivated *T. atrica* toxin is not reactivated by the same means as arachnolysin toxin; the former is regarded as a simple toxin and the latter as complex. These toxins react differently with mice and with rabbits. Eggs of *T. parietina* were examd. for toxins but none found. L. W. RIGGS.

A theory of nerve conduction. A. G. MAYER. Washington. Carnegie Inst. *Proc. Nat. Acad. Sci.* 2, 37-42(1916); cf. *C. A.* 9, 1349.—An attempt was made to prep. a strictly neutral distd. water for use in dilg. the sea water, in order to det. the true effects of the Na, K, and Ca cations without the disturbing effects of the H and OH ions. A concn. of 6×10^{-8} OH in sea water is a maximal stimulant for nerve conduction, but becomes a depressant if its concn. be further increased. Expts. were made upon 71 specimens of *Cassiopea xamachana* and the results shown in tables and by curves. M. suggests that adsorption may play a fundamental role in nerve conduction, and that the only cations which are necessary to the reaction are the adsorbed Na, K, and Ca, the rates of nerve conduction being proportional to the concn. of these adsorbed ions. H and OH ions are not adsorbed but act independently as accelerators or depressants according to their concn. The mechanism of conduction according to M.'s theory is illustrated by diagrams. L. W. RIGGS.

12. FOODS.

W. D. BIGELOW AND F. F. FITZGERALD.

A new preservative. O. LÜNING. *Z. Nahr.-Genussm.* 30, 466-7(1915).—In examg. a marmalade for preservatives L. found *m*-cresilic acid, which reacts very similarly to salicyclic acid. The question of its effect upon health is brought up.

L. D. ELLIOTT.

Glucose in preserves made from preserved fruits. C. F. MUTTELET. *Ann. fals.* 8, 132-5(1915).—Fruits are commonly preserved with sucrose and glucose. Heretofore preserves made from fruits to which glucose had been added have had to be labeled so as to declare the presence of glucose. Analyses of 18 samples of preserved fruits from representative French manufacturers show that glucose from 6.13 to 38.47% is used in these products. In view of these analyses, the Dept. for Suppression of Frauds ruled (April 8, 1915) that glucose in jellies and marmalades made from preserved fruits shall not be considered an adulteration when the products are labeled to show they are made from preserved fruits. H. R. SMITH.

The utilization of waste oranges. W. V. CRUSS. Calif. Agr. Expt. Sta., *Bull.* 244, 157-79(1914).—In Calif. from 5 to 20% of the orange crop is rejected owing to slight defects in shape, color or size, or to slight injury to the skin. These waste fruits are used in the manuf. of marmalade, candied peel, bottled pulps and sirups, various liquids and beverages and chem. prepn.s., such as exts., oils and citrates. Examn. of these products showed that those prepd. by chem. or mechan. means were generally of good quality, while those involving some fermentation process were generally bad. The prepn. of orange juice, orange wine and orange vinegar were investigated in the Zymological Lab. of the Univ. of Calif. *Orange juice*: It is recommended that the freshly expressed juice be allowed to defecate until it becomes fairly clear. To prevent fermentation during this period and to check the development of a bitter flavor, a moderate amt. of $K_2S_2O_8$ should be added to the juice, immediately after crushing. The defecated juice should be immediately and pasteurized, or pasteurized in barrels and kept un- bottle it. Sterilization should take place at

180° to 185° F., at which temp. the flavor is not appreciably affected. *Orange vinegar*: The fresh juice should be treated with 4 to 6 oz. of $K_2S_2O_8$ per 100 gal. of juice (= 0.025%) and the juice allowed to stand for 24 hrs. or more, after which it is drawn off and fermented with pure yeast. Immediately after fermentation it is drawn off from the yeast and stored in well-filled closed barrels or tanks until it is convenient to turn the juice into vinegar. One-fourth of its vol. of strong vinegar is then added to prevent the growth of wine flowers and promote vinegar fermentation, which should take place in containers allowing a good exposure to the air. *Orange wine*: The fresh juice is defecated with $K_2S_2O_8$ to prevent fermentation for a short time. The clear juice is then fermented with pure yeast and filtered. The wine may be kept in well-filled bottles without pasteurization.

E. J. C.

Recent experiments on the storing of grapes in various gases. G. DALMASSO. *Rivista viticoltura, enologia ed agraria* [5] 21, 217-9(1915); *Bull. Agr. Intell.* 6, 993-4. —A few yrs. ago Sannino carried out some expts. on the storing of grapes in inert gases, with the object of preventing their drying up or turning moldy. The grapes, however, while retaining for a certain length of time a good appearance externally, acquired a taste which showed that some fermentation had taken place, rendering them unfit for the table. D. has repeated the expts., first with inert gases, such as CO_2 and deoxygenated air, then with active gases, such as ozonized air and O, but with no better results. With CO_2 , both in the diffused light of the lab. and in the darkness of the cellar, alcoholic and butyric fermentation took place. With deoxygenated air, after 53 days alcoholic fermentation set in with liberation of CO_2 . With ozonized air and with O the color kept better, but fermentation set in as in the case of the deoxygenated air. In practice, therefore, though this method prevents the formation of mold and preserves the appearance of the grapes, it is not to be recommended, for in less than 2 months the compn. and taste of the fruit is much altered.

E. J. C.

Manufacture and use of unfermented grape juice. G. C. HUSMAN. U. S. Dept. Agr., *Farmers' Bull.* 644, 16 pp.(1915).—This publication states briefly the way in which unfermented grape juice is made and preserved, both for commercial and domestic use, as well as the fundamental processes and principles involved. Practical suggestions are offered. The subject is dealt with under the following headings: Compn. of the grape, analyses of grape must, causes of fermentation, methods of preventing fermentation, flavor and quality of grape juice, home manuf. of grape juice, valuable appliances for home use, com. methods of making must, and the use and food value of unfermented grape juice.

E. J. C.

The caffeine content of Java tea. J. J. B. DEUSS. *Chem. Weekblad* 12, 938-43 (1915).—A comparison of the modified method of Romburgh and Nannings and the refractometer method for the detn. of caffeine in Java tea. The accordance of both methods is satisfactory. There is no relation between the caffeine content of tea and the altitude of the plantations. The detn. of caffeine in tea as a means to its valuation is justified only in the case of adulteration with tea already extd. or by the addition of leaves other than tea. A caffeine content of less than 3% is sufficient indication of adulteration in the case of Java tea.

J. T. FLOHL.

Antihemolytic power of tea leaves. MAGGIORA AND FERRON. Padua. *Gass. osped.* 1914, No. 65; *Zentr. Biochem. Biophys.* 18, 199(1915).—A new method which depends upon the detection of an antihemolytic substance (with respect to saponin) is proposed for the identification of tea leaves. Boil 1 g. of the tea leaves under examn. for 10 min. in 100 cc. H_2O , filter hot, conc. the filtrate in a porcelain dish on a H_2O bath and dissolve the residue in 30 cc. of a 2% Na citrate soln. at 50°. After cooling and deposition remove several cc. of the clear liquid with a pipet and filter, add 2 cc.

washed calf blood corpuscles in 1% suspension (in physiol. NaCl soln.) to 0.2 cc. of the filtrate, shake slightly, add the saponin after 5 min., shake again and det. the result after standing 3 hrs. at 37° and 12 hrs. at room temp. Genuine tea leaves exhibit antihemolytic power in greater or less degree. When the test gives negative results or results which are not definitely positive the suspicion is justified that the leaves are not genuine tea leaves or that they have been exhausted or poorly preserved or sophisticated in some manner.

H. S. PAINE.

The examination of spices. C. ARRAGON. *Mill. lebensm. Hyg.* 6, 160-3 (1915).—A continuation of previous work (*C. A.* 9, 1945). The detn. of pentosans in spices by the Tollens method (treatment with HCl, distn., and detn. of furfural by phloroglucinol in the distillate) sometimes gives valuable information as to their purity. The following percents of pentosans, calcd. on the dry spices, are reported: White pepper (Muntok) 3.4, (Singapore) 3.9; black pepper (Batavia) 7.9, (Java) 8.8-9.1. (Telichery) 7.8-8.2; long pepper, 6.0; Cayenne pepper, 12.7; cinnamon (Ceylon) 14.3-14.5, (China) 9.4-9.5; nutmeg, 2.5; Bombay mace, 5.7-6.0; cloves, 8.9-9.6; Spanish anis, 7.3; Star anis, 11.8-12.2; Japan anis (*I. religiosum*), 10.4; cumin, 7.1; coriander, 13.7-13.9; cardamom seed (Ceylon) 6.4-6.9, (Malabar) 4.5; ginger (Japan) 5.0, (Bengal) 6.4.

H. S. BAILEY.

White pepper. M. S. SALAMON AND W. M. SEABER. *Chemist Druggist* 88, 146-7 (1916).—Whole white pepper from various sources gave crude fiber as follows: Penang (limed) 5.5, Penang (unlimed) 4.9, Singapore 4.2 and 4.4, Muntok 4.2 and 3.5, Siam (decorticated in London) 1.5%. Ground "home decorticated" samples gave the following figures: "Best white" 1.0, others 2.6, 2.6, 3.0 and 3.2%.

C. O. EWING.

Chemical composition of Hungarian flower honeys. S. WEISER. *Kisérlet Közlém.* 18, 365-6 (1915).—Analytical data are given regarding a number of samples of honey made from several different flowers.

E. H.

The mineral constituents of honey. KAPPELLER AND A. GOTTFRIED. *Ber. Naturhist. Untersuch. Amt. Magdeburg* 1913, 15, 16.—The analytical data presented show that the ash of honey contains from 10 to 58% of P_2O_5 .

E. J. C.

Sugar-honey. Artificial honey. FR. G. SAUER. *Pharm. Ztg.* 60, 798-9 (1915).—Further directions are given for the inversion of sucrose with lactic acid and the prepn. of artificial honey.

W. O. E.

A simple colorimetric method for the determination of free reducing sugar and total carbohydrates in miscellaneous food materials. A. BERNHARD. *Diss. Brooklyn Polytech. Inst.*, June, 1915; *Sugar* 17, No. 11, 41-2 (1915).—B. uses the color reaction produced by heating dextrose in alk. soln. with picric acid with the formation of picramic acid. Grind the sample (2-5 g.) in a mortar with H_2O , transfer to a 100 cc. cylinder, dil. to the mark and shake thoroughly. Sat. the soln. with picric acid (1-3 g.), shake, allow to stand a few min. and filter. Pipet 2 cc. of the clear, protein-free filtrate (contg. 0.4-1.2 mg. sugar) into a narrow, graduated test-tube, add 3 cc. 20% Na_2CO_3 soln., heat in a boiling water bath for 10 min. and dil. to 10 cc. with warm water. Compare in the Hellige colorimeter with standard picramic acid solns. The standard picramic soln. is made by heating 0.2 g. picramic acid and 0.4 g. anhydrous Na_2CO_3 with 60 cc. H_2O in a casserole, cooling and making up to a vol. of 1000 cc. with H_2O . The wedge of the colorimeter is filled with this soln. To varying amts. of a 0.1% soln. of anhydrous dextrose are added 2 cc. satd. picric acid soln. and 3 cc. 20% Na_2CO_3 soln. in a long, narrow test-tube graduated at 5 and 10 cc. The tubes are heated from 10 to 15 min. in a boiling water bath, made up to 10 cc. with hot H_2O , thoroughly mixed and immediately compared with the wedge of picramic acid in the colorimeter. Tables are given showing colorimetric readings with

amts. of dextrose and lactose. For the

detn. of the total carbohydrate, including starch, a sample of the material is hydrolyzed according to the method of the A. O. A. C. The soln. is nearly neutralized, made up to 250 cc. and an aliquot clarified with basic Pb acetate and dry Na_2CO_3 . Dil. 5 or 10 cc. to 100 cc. with satd. picric acid soln. Use 2 cc. for the detn. For milk and milk products, 1 cc. of milk or a weighed sample if a dry prepn. is used, is made up with H_2O to 100 cc., dry picric acid added, the whole shaken and filtered. The usual quantity (2 cc.) is used. A table is prepd. for lactose as previously described for dextrose. A comparison of the method with other methods shows results with a variety of food materials to be in excellent agreement.

A. G.

Starch determination by method of Baumert and Bode. A. HUIZINGA. *Chem. Weekblad* 13, 198-205 (1916).—Duplicate detns. according to the method of B. and B. sometimes vary 1.2% when 3 g. samples are used. This variation may be due to 2 causes: (1) reducing substances may be formed during the heating in the autoclave; (2) a portion of the starch may be rendered insoluble during the cooling of the soln. in the autoclave. The mixt. should therefore be filtered as soon as possible after cooling, and even then the results will be low.

P. J. DONK.

The acidity of meal. TH. VON FELLEBERG. *Mitt. lebensm. Hyg.* 6, 145-50 (1915).—Lüers and Adler (*C. A.* 9, 2284) pointed out errors in the Kreis-Arragon method for the detn. of acidity in malt and barley; also that the acidity was due partly to inorganic phosphates formed by enzymatic action. The method proposed by L. and A. has several drawbacks, due to the difficulty in titrating phosphates with phenolphthalein in the presence of indefinite amts. of Ca, Mg, Fe, etc., and the loss of volatile acids during heating with EtOH. The following method gives more exact and concordant results on meals: Rub to a thin paste 10 g. meal in 20 cc. H_2O , add 80 cc. more H_2O , 1 cc. 10% CaCl_2 soln. neutral to phenolphthalein, 0.5 cc. 2% phenolphthalein and 5 cc. 0.1 *N* NaOH (more if needed to make alk.). Titrate back to neutrality with 0.1 *N* HCl, allow the soln. to settle a min., then add another drop of phenolphthalein to be sure it is neutral, and a drop of NaOH, which should restore the red color. The relation of the NaOH to HCl should be detd. in 100 cc. of H_2O containing 1 cc. of 10% CaCl_2 , and the acidity expressed in terms of cc. 0.1 *N* NaOH required to neutralize 100 g. of meal. Feed meals, as shown by several expts., give low results by this method, as the acid does not all go into soln. in the cold. If the meal is rubbed up in 100 cc. of boiling H_2O , 1 cc. of CaCl_2 soln. being also added, then quickly cooled and titrated as in the preceding method, the true acidity can be detd.

H. S. BAILEY.

Acidity in wheat flour. L. A. FITZ. *Oper. Miller* 20, 36-8 (1915); *Expt. Sta. Record* 33, 64.—Analyses made by J. W. Calvin and Leila Dunton at the Kansas Expt. Sta. are reported. Judging by the results with different millings of the same grain, high acidity is apparently an unreliable test for unsoundness in flour. The acidity is in part at least attributed to phosphates and amino acids normally occurring in flour.

E. J. C.

Sodium chloride and ash determination in bread. A. M. KNOTTNERUS. *Chem. Weekblad* 13, 205-9 (1916).—A direct method for the detn. of NaCl by extn. with acid, and the detn. of ash from the same sample after titration. Add 100 cc. of 0.1 *N* HCl and 100 cc. 0.1 *N* HNO_3 to each of two 10 g. samples of finely powdered, dry bread and shake thoroughly. Let stand a short time, and filter. Wash with distd. H_2O , dry and ignite. Neutralize 10 cc. of the filtrate with NH_4OH and add a few drops of AcOH, then titrate with AgNO_3 according to Mohr. The added NaCl can be calcd. after correcting for the 0.1 *N* HCl used and for the Cl ordinarily found in flour. The total ash is the sum of the NaCl found and the ash of the extd. residue. The ash free from added NaCl is the sum of the ash of the extd. residue and the NaCl ordinarily found in flour.

P. J. DONK.

The physical chemistry of bread. LORENZ. *Chem. Ztg.* 37, 783(1913); *Expt. Sta. Record* 33, 162.—From the studies of the structure of both fresh and stale bread L. concludes that as the loaf ages the structure of the starch granules is modified and the starch gives up its water content to the protein part of the loaf. He regards the fresh loaf as an unstable form and the modified starch granules as a permanent characteristic of stale bread.

E. J. C.

The microscopic determination of the quantity of foreign materials in powders. A. MAURIZIO. *Mitt. lebensm. Hyg.* 6, 156-60(1915).—A review of various microscopic methods for the quant. detn. of the constituents of different materials. While in special cases as the analysis of paper such methods may yield approx. results, there is little hope of detg. even roughly the quantity of the different constituents in mixts. like compound flours or stock feeds.

H. S. BAILEY.

Milk investigations—value of rosolic acid-alcohol test. L. BAHR. *Z. Fleisch. u. Milchhyg.* 24, 228-33, 251-6, 370-6, 398-406, 472-7(1914); *Expt. Sta. Record* 33, 115.—Milks from 105 cows examd. with the rosolic acid-alc. test (*Expt. Sta. Record* 26, 87) gave a positive reaction in about 16%. This was especially true in those cases in which the titer against *N* alkali was somewhat below normal. The reaction probably depends on the presence of secondary or tertiary phosphate. The majority of milks giving a positive test contained many bacteria, leucocytes and fibrin. A few tests made with methylene blue indicated that this substance had no relation to the number of bacteria present in the milk.

H. A. LEPPER.

Composition of grain, flour and milling offals of four varieties of Irish wheat. H. HUNTER. *Dept. Agr. and Tech. Instruction for Ireland J.* 15, 550-62(1915).—Tables are given of analyses showing the usual detns. on Red Fife, White Queen, White Stand Up and Square Head Master wheats.

H. A. LEPPER.

Ash content of canned vegetables. A. F. MORGAN. *J. Home Econ.* 7, 72-7 (1915).—The ash content of peas canned by different methods was found to be less than that of the corresponding fresh peas. Calcd. to H_2O -free basis 46.1% less was found in peas bleached and canned by the usual high pressure process, 50% less in those blanched and canned by the standard home process and 22.6% less in those unblanched and canned by the latter process. The % of extn. of P_2O_5 in each case is rather higher than the total mineral extn.

H. A. LEPPER.

Specific gravity and solids in tomato pulp. W. D. BIGGLOW AND F. F. FITZGERALD. Nat. Canners Assoc., *Bull.* 7, 3-15(1915); cf. *C. A.* 9, 2405.—Various methods for detg. sp. gr. in tomato pulp are compared and a method suggested involving the use of a centrifuge. It is believed to give accurate results. Methods of controlling concn. to definite vol. are discussed. Tables are included giving in parallel columns the sp. gr. and percent solids in pulps of various density.

E. J. C.

A new centrifugal method for the determination of fat in cocoa and cocoa products. W. D. KOOPER. Leipzig. *Z. Nahr.-Genussm.* 30, 453-61(1915).—A rapid method for the detn. of fat in cocoa products involving the use of Neusal reagent. A special app. is described.

L. D. ELLIOTT.

The determination of fat in cocoa and chocolates by the extraction method. W. D. KOOPER. Leipzig. *Z. Nahr.-Genussm.* 30, 461-6(1915).—K. finds that several factors affect the amt. of ext. obtained by the usual Soxhlet method. A small thimble will tend to give lower results, due to the closer packing of the sample. A faster circulation of ether results in an increased amt. of ext. Investigation as to the cause of the variation showed that there was present in the ether soln. a slight amt. of non-fatty matter which gradually settled out as the ether was distd. off. Upon drying the ext. at 103°, the fat assumed a milky appearance, or a crusty deposit formed on the

bottom of the flask. To purify the fat, the ext. is dried to const. wt., the wt. of fat + impurity obtained, after which 50 cc. of ether are added. The impurity remains undissolved and the ether soln. of purified fat is decanted through a filter into a tared flask, and the ext. dried and weighed as usual. A large amt. of residue from a number of detns. was collected and identified as theobromine. On a number of cocoa and chocolate samples, the av. amt. of theobromine extd. by the 3.2 l. of ether passing through the sample in the extrn. period of 16 hrs. was 0.34% for chocolate, and 0.52% for cocoa.

L. D. ELLIOTT.

The composition of milk as affected by increase of the amount of calcium phosphate in the rations of cows. A. LAUDER AND T. W. FAGAN. *Proc. Roy. Soc. Edinburgh* 35, 195-202 (1914-15).—The addition of Ca phosphate to the rations did not increase the amt. of P_2O_5 in the milk. The extra Ca phosphate did not affect an increase in the percentage of fat, ash, or solids-not-fat. No definite effect on the yield was observed.

E. J. C.

The refraction of milk serum. L. KISS. *Kisérlet. Köszlem.* 17, 24-34 (1914); *Expt. Sta. Record*, 33, 715.—The refraction of the $CaCl_2$ serum of milk dild. with water and preserved with CH_2O or $K_2Cr_2O_7$ was studied. It was found that the refraction of the $CaCl_2$ serum falls after the milk is dild. with water. For each 1% of water added up to 10% the refraction drops approx. 0.25° . Of the preservatives recommended for keeping milk samples only CH_2O has an inappreciable influence on the refraction. On the other hand if 0.1% $K_2Cr_2O_7$ is employed the refraction rises from 0.3 to 1.1° and with 0.05% $K_2Cr_2O_7$ from 0.1 to 0.65° . The calcn. of the sp. gr. with Wiegner's formula from the refraction of the $CaCl_2$ serum yielded very good results. E. J. C.

Catalase and reductase determination in cow milk in practice and the relation between catalase and reductase on the one hand and the specific gravity, fat, and acidity on the other. A. STETTER. *Milchw. Zentr.* 43, 369-81 (1914); *Expt. Sta. Record* 33, 414.—The morning and evening milk from 2 dairies was examd. fairly regularly during the year 1913 for sp. gr., fat content, reductase and acidity. The cows were fed chiefly hay and various concentrates, with beet tops and leaves during the fall months. No relation was found to exist between the catalase and reductase figures and the sp. gr. and fat content of milk. On the other hand, a high acidity degree almost always pointed to a high reductase content. No correlation was found between acidity and the catalase figures, as milk with a high acid value often showed a normal catalase figure. It often occurred that the catalase and reductase figures of the morning and evening milks were alike but, generally speaking, the figures for each were highest in the evening milk. The catalase figure varied considerably from day to day and the reductase test also showed very marked variations. In most instances a milk which decolorized (reductase test) in 15 min. also had a high acid value. Although a high catalase and reductase figure lead to a suspicion of pathological milk, still one must be cautious when pronouncing a condition pathological on the basis of these tests.

E. H.

Some physiologic and biochemical observations on milk. W. T. CARSTARPHEN. *Va. Med. Semi-Mo.* 20, 319-26 (1915); *Expt. Sta. Record* 34, 164.—This article is a summary and digest of recent exptl. data regarding the nutritive value of milk. The work reviewed has to do chiefly with the lime, Fe and P content of milk. A bibliography is appended.

E. J. C.

Further observations on the presence of antibodies for *Micrococcus melitensis* in the milk of English cows. S. L. CUMMINS, C. J. COPPINGER AND A. L. URQUHART. *J. Roy. Soc. Med.* 7, 36-41 (1914); *Expt. Sta. Record* 33, 84.—In a series of two gave positive results and one of these was found

to agglutinate *M. melitensis* in dilns. varying from 1:250 to 1:1000 at different times. The milk of this cow was also investigated for opsonins and deviating substances, and it was found that "the milk, whey, and blood serum of the cow behaved toward *M. melitensis* in a manner comparable to the body fluids of animals suffering from, or immunized against, this organism. Due allowances were made for differences in concentration of 'antisubstances' and degrees of immunity." E. J. C.

Fat content of Swiss Emmenthaler cheese. R. BURRI. *Milchw. Zentr.* 43, 556-8 (1914); *Expt. Sta. Record* 33, 81.—Analyses of 641 samples of Swiss Emmenthaler cheese show that the av. fat content in the dry matter ranges between 45 and 50%, although some samples test as low as 40%. E. J. C.

Fat content standards for Danish types of cheese. ORLA-JENSEN. *Milchw. Zentr.* 43, 540-2 (1914); *Expt. Sta. Record* 33, 81.—This article discusses the fat content of various types of Danish cheese. E. J. C.

Methods of making some of the soft cheeses. W. W. FISK. New York Cornell Sta., *Circ.* 30, 41-62 (1915).—Methods of making pot, baker's and cottage, Neuschâtel, cream and club varieties of soft cheese are described on the basis of tests carried on for several yrs. at the station. Field data, analyses, and a bibliography of 28 references are included. E. J. C.

Experiments in cheese-making from milk of different fat contents. A. V. LUND. *Beretning fra der Kgl. Veterinaer-og Landbohøjskoles, Laboratorium for Landøkonomiske Forsøg* 86, 5-47 (1914); *Bull. Agr. Intell.* 6, 988-90.—In Denmark various classes of cheeses are distinguished by the proportion of fat to albuminoid content (the cheese coeff.). Investigations were made to det. this ratio for fresh and stored cheeses, the coarse and fine division of the curd, cheeses made from pasteurized and unpasteurized milk, the milk of Jersey cows, etc. The conclusions are: (1) The coeff. can be accurately estd. from the fat % of the cheese milk and conversely the fat % can be calcd. from the coeff.; the factor in the case of milk from Danish cows is $37\frac{1}{2}$ ($\frac{9}{10} \times 100$). (2) The coeff. of the different kinds of cheese known commercially as whole milk, $\frac{1}{2}$, and $\frac{1}{4}$ whole milk, and skimmed milk cheeses are distinct enough to allow of the various kinds being distinguished by this means. In spite of considerable variations in the coeff. of the same sort of cheese, it has been found that the minimum for a whole milk is higher than the max. of a $\frac{1}{2}$ whole milk and similarly for the other types. (3) Such factors as whether the milk is pasteurized or not and whether the curd is coarsely or finely divided exert some influence on the coeff., but not enough to modify the conclusions in 2. (4) Length or method of storing has little effect on the coeff. as detd. by analysis. (5) As the coeffs. are merely exptl. figures they cannot be used as type values but may serve as guides for the detn. of the latter. (6) The yield of cheese can be roughly estd. when the amount of fat and albuminous substances in the "cheese milk" is known. (7) Cheeses from the milk of Jersey cows have higher coeffs. than those from the milk of ordinary Danish cows, yet the coeffs. of the former were relatively too low, owing to the large amt. of albuminous present. (8) The factor $37\frac{1}{2}$, given in (1), cannot be used in case the milk comes from Jersey cows, a factor 30 ($\frac{9}{10} \times 100$) being necessary. (9) The milk of Jersey cows gave a much larger cheese yield than ordinary milk due to the larger fat and albuminoid content. (10) A single examn. showed no characteristic difference in quality between cheeses made from Jersey or Danish milk. (11) Any given "cheese milk" can be altered by the addition of skimmed milk or whole milk (or even cream) in such a way as to obtain the desired coeff. in the cheese to be produced. H. A. LEPPER.

The significance of solanine as potato poison. DROST. Hanover. *Pharm. Zentralhalle* 56, 311-2 (1915).—Solanine in potatoes occurs chiefly in the outer parts,

which may contain as much as 70% of the total amt. The total amt. did not increase during storage and germination. The formation of solanine by the action of molds and bacteria, especially *B. solaniferum. colorabile*, could not be verified. The solanine content of potatoes even under favorable conditions is so small that illness after the eating of potatoes cannot be attributed to that alkaloid but is more probably due to the action of yeasts and bacteria.

C. O. EWING.

Ash manna: Production in Italy; composition; adulteration. G. MAROGNA. *Ann. stas. chim. Agr. sper. Roma* [2] 7, II, 77-145 (1915); *Bull. Agr. Intell.* 6, 835-6 (1915).—The manna-producing ash, represented by many species or varieties, is cultivated only in Sicily, and chiefly in the vicinity of Palermo and Cefalù, covering about 13,800 acres. The product goes mainly to S. and Central America; part of the crop is used in Sicily for the extrn. of mannitol. M. has collected and analyzed a number of genuine samples of manna, to try to fix limits within which the compn. may vary. The data are summarized in a table. M. describes in the original his method of manna analysis and the means of detecting the most common adulterants.

F. W. SMITHER.

Examination and judging of egg noodles by means of specific serums. F. GÖTHER. Hamburg. *Z. Nahr.-Genussm.* 30, 389-99 (1915).—The presence of egg in noodles may be detd. quant. by means of a specific serum. It is also possible to distinguish between a product containing egg white and egg yolk by the same means, the serum employed in each case being obtained from rabbits injected with the particular portion of the egg sought. *Preparation of the serum:* Beat up the entire contents of an egg, pour into a sterile cylinder and dilute with an equal vol. of glycerol. This suspension will keep indefinitely in an ice box. Immediately before injecting, dilute the glycerol suspension with 9 vols. of physiological salt soln. Inject rabbits intravenously with this soln. using 5 cc. for each injection and repeating the operation 4-5 times at 5-7 day intervals. Bleed the animals, heat the serum for 30 min. at 56° and preserve by the addition of 0.1% of diaphtherin. The serum should produce a pronounced turbidity when 0.1 cc. is introduced into a test tube containing 2 cc. of a 1/10,000 or 1/20,000 diln. of whole egg in physiological salt soln. *Detn. of egg substance in noodles:* Grind the sample so that it will pass through a 0.3 mm. mesh sieve. Introduce 4 g. of the powder into a 100 cc. volumetric flask, fill almost to the mark with sterile physiol. salt soln., shake until the mixt. is uniform, and allow to stand in a refrigerator overnight. Make up to mark with physiol. salt soln., mix thoroughly and filter through a dry filter rejecting the first 30 cc. of filtrate. Introduce 4 cc. of the filtrate into a special tube, the lower, or closed portion of which is constricted and graduated into divisions of 0.001 cc. each, the upper portion of the graduated section flaring at a small angle until it meets the upper or main portion of the tube. Prepare a 1-5 diln. of the serum in physiol. salt soln. and add 1 cc. to the contents of the tube. Mix carefully, place in an incubator at 37° for 1 hr. and then centrifuge for 5 min. in a machine giving 3000 r. p. m. Compare the vol. of the ppt. in the tube with ppts. obtained from noodles of known egg content treated in exactly the same way. G. prepd. noodles containing, resp., 0.0, 10, 25, 50, 75 and 100 g. of egg substance per lb. (German) of flour and obtained, resp., 0.0, 4, 11, 18, 29.5 and 32.5 cu. mm. of ppt. Of 20 commercial samples 65% showed no egg and the remainder the following number of g. of egg substance per lb.: less than 10 g., 20%, 10-25 g., 10%, 25-50 g. 5%. In order to test separately for egg white and egg yolk the procedure is the same except that egg white and egg yolk, resp., are substituted for whole egg in prepg. the serum. The serums are specific for the substances in question and do not react with other proteins.

A. F. SEEKER.

Sucrose content of potatoes in relation to age and treatment with liquid air. H. I. WATERMAN. *Chem. Weekblad* 13, 122-7 (1916); cf. *C. A.* 10, 131, 357.—W. found

that the change of starch (in old potatoes into sucrose during drying at 40° is greater than in the case of newly grown ones. Sucrose increase during drying at 40° in old potatoes was 3%; in newly grown potatoes, 0.7%. W. succeeded in destroying the power of conversion of starch into sucrose through the application of very low temp. Potatoes were submersed in liquid air for 5-10 min. and it was found that after drying at 40° practically no sucrose increase could be found. J. T. FLOHL.

Chemistry of flesh foods. II-IV. Composition and nutritive value of the retail cuts of mutton and lamb. *Trans. Proc. New Zeal. Inst.* 47, 569-72(1914).—This is a continuation of previous work (cf. *C. A.* 7, 658). A carcass of a mutton and one of a lamb were dressed and sepd. into retail market cuts. A table is given of analyses, showing the chem. compn. of the boneless meat of these cuts. It was found that the constituents (mineral salts and meat bases) which give flavor to cooked meat show little difference in the various cuts. The relative market prices charged for the various cuts are not governed by the relative food value or palatability of the meats.

H. A. LEPPER.

The ripening of meat. H. KREN. *Wiener Tierärztl. Monatschr.* 1, 585-9(1914); through *Expt. Sta. Record* 33, 460.—Analytical data are reported regarding samples of meat kept in cold storage from 1 to 8 days. The results indicate that the ripening of meat depends upon the hydrolytic cleavage of the protein. E. J. C.

Essence of chicken. Essence of beef. FR. G. SAUER. *Pharm. Ztg.* 61, 56-7 (1916).—Directions are given for the prepn. of these gelatin-like products.

W. O. E.

Preservation of meat. A. GURINI. *Clin. vet. (Milan) rass. pol. sanit. e ig.* 37, 669-78, 711-24, 764-82, 799-825(1914).—This article includes some analyses showing the compn. of fresh and preserved meats. E. J. C.

The adulteration of preserved beef with horse meat. G. ISSOGLIO. *Ann. r. accad. agr. Torino* 57, 204-13(1914); *Expt. Sta. Record* 34, 113.—Methods are given for the detection of horse meat in canned beef. E. J. C.

Meat flour. F. BAUMANN. *Konserv. Ztg.* 16, 97, 98, 101-2, 105-6(1915); *Expt. Sta. Record* 34, 163.—In this summary and digest of exptl. data B. describes the method of prepn. and the properties of flour made by drying and milling lean meat. The fact is emphasized that it is necessary to use meat contg. as little fat as possible, as the best safeguard against rancidity, and to remove most of the water. In addition, it has been found advisable to use about 3% of NaCl as a preservative. Meat flour prepd. in this way is said to possess a good odor and taste. Due to its high protein content it is a valuable food. It is also well digested. E. J. C.

Durra (*Sorghum vulgare*) as a substitute for wheat in bread-making. A. CASSELL. *Agricoltura coloniale* 9, 217-27(1915); *Bull. Agr. Intell.* 6, 983-4.—Durra flour is of excellent quality, being fine, soft, smooth, with a white color inclining to pink. The resultant loaf from good wheat flour 75% and Durra 25% was well risen, light, with a smooth, brownish yellow, hard, friable crust, adhering completely to the crumb; this latter was uniform in color, light, elastic, with numbers of small round eyes uniformly distributed, while its flavor was excellent, and superior to that of other bread made from wheat with the addition of rice, rye, or potatoes. Analysis of a sample of this bread gave in %, starch 50.79, ash 1.66, fats 0.44, protein 8.33, H₂O 35.23, and fiber (by difference) 3.55. Comparative analyses of Durra with other cereals are given. Durra is a complete food containing a sufficient amt. of protein and a large quantity of starch. Its grain yields less bran than wheat and consequently more flour (about 79%). It lends itself better to bread-making and mixing with wheat than maize flour. The ratio of protein in Durra bread to maize bread is 7 to 4. H. A. LEPPER.

Chemical analyses of maize and oats cultivated in Eastern Republic of Uruguay. J. Prug y Nattino, Republica Oriental del Uruguay, Ministerio de Industrias. Inspeccion de Ganaderia y Agricultura, *Boletín* 14, 29 pp.; *Bull. Agr. Intell.* 6, 1332-3. —Tables are given of analyses of maize and oats grown in the Eastern Republic of Uruguay.

H. A. LEPPER.

Chemical analyses of forage plants of Spain. R. SÚAREZ Y BERMÚDEZ. *Separate*. Madrid. *Langa y Compania* 1912, 94 pp.—Analyses are given of *Brachypodium pinnatum*, *Phragmites gigantea*, *Bromus rubens*, *Aphyllantes monspeliensis*, *Crocus sativus*, *Urtica urens*, *Arthrocnemum macrostachyum*, *Chenopodium album*, *Salsola vermiculata*, *Atriplex halimus*, *A. rosea*, *Kochia prostrata*, *Amaranthus albus*, *Roemeria hybrida*, *Glaucium corniculatum*, *Moricandia arvensis*, *Carrichtera velle*, *Malcomia africana*, *Biscutella laevigata*, *Conringia orientalis*, *Anthyllis cytisoides*, *Ononis tridentata*, *O. viscosa*, *Hedysarum humile*, *Onobrychis saxatilis*, *O. eriophora*, *Coronilla minima*, *Lupinus angustifolius*, *Vicia cracca*, *Zygophyllum tobago*, *Tribulus terrestris*, *Lithospermum fruticosum*, *Teucrium chamaepitys*, *Crucianella maritima*, *Xanthium strumarium*, *Silybum marianum*, *Andryala ragusina*, *Sonchus crassifolius*, *Artemisia herba-alba*, and *A. glutinosa*.

E. J. C.

Bulbs of very doubtful value as food. D. I. MURPHY. U. S. Dept. Com., *Commerce Reports*, No. 4, 61(1915).—Chem. analysis of bread prepd. from a mixt. of $\frac{1}{2}$ wheat flour and $\frac{1}{4}$ powdered tulip or crocus bulbs showed that the nutritive value of the wheat was lessened by the admixture. Among the objections made to the use of these bulbs as a food is the fact that the poisonous narcissus bulb may easily be mistaken for them.

E. J. C.

Uses of sorghum grain. C. R. BALL AND B. E. ROTHGEB. U. S. Dept. Agr., *Farmers' Bull.* 686, 16 pp.—Analyses of 268 air-dried samples gave the following: H_2O 9.52, protein 13.01, fat 3.29, carbohydrates 70.95, fiber 1.53 and ash 1.70%.

H. A. LEPPER.

The food value of *Stizolobium pachylobium* beans. H. S. SHREWSBURY. *Rept. Dept. Agr. Barbados* 1913-4, 27-8; *Expt. Sta. Record* 34, 262.—No evidence was found of the presence of cyanogenetic or other poisonous glucosides, saponins, fats, alkaloids, vegetable ptomaines or toxalbumins in this bean grown in Trinidad. The nutritive properties are principally due to a high content of carbohydrates and proteins. The value is less than that of soy beans chiefly because of the absence of fat.

H. A. LEPPER.

Mistletoe. ANON. *Calif. Sta. Report* 1915, 32-3.—Usual feedingstuff analyses of the whole plant, leaves and stems and branches of mistletoe are reported. The figures show a comparatively high nutritive value.

H. A. LEPPER.

Contributions to the chemistry of the soy bean. PAUL D. HAHN. *S. African J. Sci.* 12, 124-6(1915).—Analyses of a large white variety of Manchurian bean, 3 yrs. old, and a small black variety grown locally, are resp.: water, 4.80, 11.35%; albuminoids 34.07, 29.50%; oil, 17.68, 11.60%; ash, 4.23, 4.97%. On first sample only, crude fiber, 11.17%. Analyses of the ash of both samples and of the pods, hay and leaves are also given.

P. B. DUNBAR.

Investigations concerning nutritive yeast (Nährhefe). M. SCHOTTELIUS. *Deut. med. Wochschr.* 41, 817-9(1915).—Nutritive yeast contains protein 51, ash 7, fat 3, N-free extractives 28 and water 8%. The caloric value of 1 kg. nutritive yeast corresponds to that of 3.3 kg. beef of moderate fat content. Rough feeding expts. on 9 inmates of a jail with doses increasing from 30 to 75 g. per day led to a very moderate gain in wt. in 5 cases; 2 remained stationary and 2 lost wt. Of the controls 2 gained, 1 remained stationary and 6 lost wt.

S. AMBERG.

The utilization by the animal organism of yeast cultivated in solutions of sugar and inorganic salts. W. VÖLK. *Z. Spiritusind.* 38, 235(1915); *Expt. Sta. Record* 34, 165.—Analytical data are given showing the compn. of yeast grown in a soln. of sugar and inorg. salts. Feeding expts. with a dog are also described, the results of which indicated that the coeffs. of digestibility for protein, fat and carbohydrate were 85, 34.1, and 54.5%, resp. W. concludes from these data that artificially cultivated and brewery yeasts are equally valuable food materials and may be used occasionally to replace meat in the diet.

E. J. C.

Utilization of rice straw. N. NOVELLI. *Gior. risicolt.* 5, 147-54(1915); *Expt. Sta. Record* 34, 72.—The av. digestible nutrients of rice straw are given as protein 1, fat 0.44, and carbohydrates 28.63%. Ensiled rice straw has been found to be a desirable feed material.

The production of mineral waters in 1914. R. B. DOLE. U. S. Geol. Survey. *Mineral Resources of U. S.*, 1914, Pt. II, 175-219 (separate, published Aug. 20, 1915).

E. J. C.

Changes in the chemical composition of potable waters by javellization. Its detection. CH. O. GUILLAUMIN AND VIENNE. *J. pharm. chim.* 12, 377-87(1915).—A recent war order prescribed the addition of 1 to 3 or more mg. of active Cl per l., sufficient to be recognized by the KI starch test 30 min. after treatment. G. and V. show that absorption within 30 min. is slow, and is complete only if the water is very impure. Ordinarily, a positive test need not indicate complete sterilization. Cl absorption becomes const. at 50 mg. per l. when acting during 6 hrs. On this basis, the coeff. of Cl absorption is found as follows: To 200 cc. of filtered H_2O add 10 cc. of dil. hypochlorite (1 g. of active Cl per l.). After 6 hrs. add 3 cc. of 10% KI soln., then 20 drops of AcOH , later 100 cc. of 8% $\text{Na}_2\text{S}_2\text{O}_3$ soln., then starch paste, and titrate back with 0.01 N I till blue. A parallel detn. is made on the same vol. of distd. H_2O , and the difference in the 2 vols. of I soln., expressed in mg. of Cl and referred to 1 l., is the desired coeff. This method even detects previous javellization, since the coeff. diminishes by the exact amt. of Cl introduced previously. The effect of javellization on the ni-

trites of water, using Dane's reagent (50 cc. H_2O + 0.5 cc. of 0.1% alc. indole soln. + 1 cc. H_2SO_4) is also studied, and a *coeff. of permanganic oxidation* of javellized water is discussed. Plain wood affects Cl absorption; pitch-lined barrels should be used, and the water should be renewed frequently. S. WALDBOTT.

Experiments in water softening with zeolite-like substance. R. N. KINNAIRD. *J. Am. Water Works Assoc.* 3, 242-4(1916); see *C. A.* 10, 501. E. H.

Note on the bacteriotoxic action of water. R. GREIG-SMITH. *Proc. Linn. Soc. N. S. Wales* 39, 533-7(1914); *Expt. Sta. Record* 33, 188; cf. *C. A.* 9, 1796.—Expts. in which suspensions of *B. prodigiosus* and *B. typhi* were added to tap water, boiled and unboiled, and filtered through a Chamberland filter, showed that, as a rule, the growth of the organisms was retarded, especially in the case of the boiled water. The conclusion is reached that "ordinary tap water contains substances of the nature of bacterio-toxins, the toxicity of which is increased by boiling." E. H.

Oxygen determination according to L. W. Winkler. II. G. BRUHNS. *Chem. Ztg.* 40, 45-6, 71-3(1916).—A continuation of previous work (cf. *C. A.* 10, 235), in which the effect of the presence of Fe salts in H_2O is investigated. The following modifications of W.'s process are recommended: (1) The use of $MnSO_4$ soln. (1:1) instead of $MnCl_2$, (2) $NaOH$ - KOH soln. (1:1:2) without KI instead of $NaOH$ soln. with or without KI, (3) both solns. to be used from dropping bottles instead of with pipets, (4) the addition of KI soln. or crystals only after the Mn oxide has settled, (5) the use of moderately dil. HCl (1:1) or H_2SO_4 (1:3) instead of fuming HCl , (6) removal with a pipet of a definite portion from the flask and titration of the remainder in the flask with standard $Na_2S_2O_3$ soln., (7) the O content to be expressed in cc. N soln. per 100 cc. H_2O ("%on") or per l. ("Ln"), (8) removal of dissolved interfering substances (nitrite, org. substances) by addition of crystd. $KHCO_3$ after the Mn oxide has settled, shaking, decanting and washing, if necessary, (9) the use of H_2SO_4 , a soln. of $NaHSO_4$ or $KHSO_4$, or a soln. of Na_2HPO_4 in HCl instead of H_3PO_4 , (10) in the presence of Fe^{++} salts the O equiv. must be detd. and added, or the O detd. in the H_2O after removing Fe^{++} salts with $KMnO_4$. J. H. MOORE.

An interesting example of the surface pollution of a deep-well water. JOHN W. HILL. *J. Am. Water Works Assoc.* 3, 184-91(1916); *Eng. Contr.* 44, 386(1915).—Two test wells, each 120 ft. deep, were located 250 ft. apart. One containing signs of pollution was found to be 12 ft. from an abandoned privy into which water had been pumped. Pollution traveled down 120 ft. LANGDON PEARSE.

The development of rapid sand filters in Ohio. PHILIP BURGESS. *J. Am. Water Works Assoc.* 3, 175-83(1916); *Eng. Contr.* 44, 337-9(1915).—The art of filtration is reviewed. In 1915 1,940,000 people were served in Ohio or 38.3% of the state, with 449,690,000 gals. daily capacity. The use of lime in softening and filtration is growing, on account of the sterilization. B. concludes it is possible to treat even a badly polluted river water by rapid filters and with a sterilizing process make a very safe water. LANGDON PEARSE.

The waterworks operator's interest in epidemiology. M. F. BOYD. *J. Am. Water Works Assoc.* 3, 236-8(1916); *Eng. Contr.* 44, 475(1915).—Observation of typhoid conditions is urged, with addition of sterilization plant for emergency use. LANGDON PEARSE.

Composition of rainfall at Montevideo, 1909-12. J. SCHRÖDER. *Rev. Assoc. Rural Uruguay* 44, 381-91(1915); *Expt. Sta. Record* 34, 15.—Chem. exams. of the rainfall at the Agronomic Inst. of Montevideo (Sayago) for the whole of 1912 and for parts of 1908 and 1911 are reported. The total rainfall during 1912 was 1,504 meters

(59.21 in.), supplying 7.713 kg. of combined N per hectare (6.86 lbs. per acre), of which 3.68 kg. was ammoniacal N and 4.033 kg. was in the form of nitrites and nitrates. The rainfall of 24 months represented by the whole of 1912 and parts of 1908 and 1911 contd. 13.71 kg. of N per hectare, or 6.855 kg. annually. The amt. of NaCl brought down by the rainfall of 1912 was 87.9 kg. per hectare, and for 24 months named 165 kg.

E. J. C.

The utilization of the constituents of city sewage. PAUL FISCHER, Fürstentum-Spree, AND E. R. BESEMFELDER. Charlottenburg. *Chem. Ztg.* 40, 224-5 (1916); cf. *C. A.* 10, 239, 1066.—Discussions.

J. H. MOORE.

Economic possibilities of sludge. A. V. DE LAFORTE. *Report Prov. Bd. of Health of Ontario* 1915; *Can. Eng.* 29, 710-11(1915).—Sludge from Imhoff tanks has no commercial value as fertilizer or fuel. Extn. of grease with steam would not pay. The value of destructive distn. to recover grease, gas, NH_3 , etc., is not yet definitely settled.

LANGDON PEARSE.

The disposal of infectious sewage. P. SCHMIDT. *Intern. Z. Wasservers.* 1915, Heft 5, 39-40; *Wasser. u. Abwasser* 10, 171-2(1916).—The cesspool and pail systems are often resorted to in times of war. The latter is the more dangerous from the standpoint of infection on account of the frequent contact necessary. Cesspools should be well lined with concrete and should be fly-proof. Where conditions permit the content may be discharged into streams. The disinfection of fecal matter at the bed-side diminishes the possibility of infection from such a source.

ARTHUR LEDERER.

Sewage treatment works for Altamont Y. W. C. A. camp. H. W. TAYLOR. *Eng. News* 74, 1219-20(1915).—To handle a population of 200 with a flow of 30 gals. per capita daily, a small Imhoff tank, sprinkling filter with 2 nozzles, and secondary tank serving as dosing chamber to 3 sand filter beds were built. The effluent passes into 2000 ft. of absorption tile. The plant is operated about 4 months every year. The cost was \$1470.

LANGDON PEARSE.

Sewage farming at Nottingham, England. ANON. *Eng. Contr.* 44, 482-3(1915).—The sewage is distributed by open concrete carriers over 1923 acres, of which in 1914 708 were cultivated. 964 acres are in pasture on which cattle and sheep are fattened for market. The net profits in 1914 were \$2987.70.

LANGDON PEARSE.

The generation of hydrocyanic acid gas in fumigation by portable machines. H. D. YOUNG. *Calif. Sta., Circ.* 139, 8 pp.(1915).—This circular describes 2 portable machines for the generation of HCN for fumigation and reports a study of the accuracy of the machine method as compared with pot generation.

E. J. C.

Sewage sludge as fertilizer 15.

Purifying feed water. H. H. RALPH. *Brit.*, 21,552, Oct. 26, 1914. Feed-water is purified by heating in a vessel situated within the boiler and connected with the feed pump by a coiled pipe. The H_2O deposits its impurities in the channel at the bottom of the vessel and then passes into the boiler through openings fitted with flap valves. Provision is made for blowing out the sediment.

Softening water. OELWERKE STERN-SONNEBORN AKT.-GES. *Brit.*, 22,362, Nov. 11, 1914. Water is softened by being treated with Na_2HPO_4 at a high temp., preferably the b. p. The boiling may be continued for several mins.

Softening and treating water. H. HELLER. *Brit.*, 22,361, Nov. 11, 1914. Water is treated so as to prevent formation of boiler scale, by softening it with Na_2HPO_4 removing the ppt., and adding tannin or other vegetable ext. which prevents adhesion

of scale in the boiler. The tannin may be added outside the boiler, and the ppt. formed be removed; or the addition may be made to the H_2O in the boiler.

Removing iron and manganese from water. R. MEDITSCH. Aust., 70,822, Dec. 27, 1915. The process is dependent upon the use of previously formed reaction products as catalyzers. A portion of the H_2O , together with the reaction products just forming, is withdrawn from the reaction chamber, mixed with other known freshly forming reaction products serving to remove Mn, such as sol. or insol. Mn compds., and conducted into the current of H_2O under treatment, whereupon the entire mass is led to the reaction or contact chamber, or through a filter.

Preventing corrosion. M. REGAN. Brit., 22,289, Nov. 10, 1914. A compn. for preventing corrosion of engine boiler plates and tubes is prep'd. by boiling together 1 qt. of H_2O , 3 lb. powdered whiting, 0.5 lb. soda, 0.5 soap powder, and 0.25 lb. borax. The compn. is applied to the surfaces with a brush as a water paint or may be added to the H_2O in the boiler.

Treating sewage. W. JONES and JONES & ATTWOOD. Brit., 22,737, Nov. 19, 1914. In purifying sewage by aerating it in presence of bacterial sludge, the sewage is supplied continuously to the treatment tank, and the upper layers overflow into a second tank, in which the liquid is quiescent and from which the sludge is returned to the first tank.

Sewage. W. JONES and JONES & ATTWOOD. Brit., 22,736, Nov. 19, 1914. In purifying sewage by aerating it in presence of bacterial sludge, the tank containing the sludge is gradually filled with sewage, and the aeration is carried out during the filling, so that the purification is completed shortly after filling. The contents are allowed to remain quiescent, and the upper layers of liquid are then drawn off. When a number of tanks are employed, the valves for supplying air and sewage and for discharging the liquid are operated in sequence by automatic means, such as float valves, or a water-clock or other time-piece operating pneumatic or elec. devices, so that the operation is continuous.

15. SOILS AND FERTILIZERS.

R. O. E. DAVIS.

The humification of the constituents of plant organisms and the effect of natural agents upon it. A. TROUSKY. Univ. Petrograd. *Selskoye Khosiaistvo Liesovodstvo* 247, 575-605(1915); through *Bull. Agr. Intell.* 6, 1453-4(1915).—The processes of decompn. of the different constituents of plant organisms and of various mixts. of these constituents were studied separately. Lignin, proteins, starch, chlorophyll, tannic substances, phlobaphenes, some fats, and gums are the direct sources of the humus formed from plant residues on the surface of the soil; cellulose, hemicellulose, mono- and di-saccharides, glucosides, organic acids (including amino acids) do not give rise to humus under these circumstances. The transformation of fungi into humus was experimentally verified. All the organic constituents utilized by microorganisms for their nutrition may become indirect sources of humus. Typical black humus is rapidly formed only when all the following constituents together take part in its formation: lignin, proteins, pigments and tannins; in a greater length of time it may also be formed by the mixt. of lignin and proteins and also by the latter alone. A certain correlation is observed between the artificial and the natural formation of humus, in that in natural surroundings humification is restricted to those organic compds. which readily undergo a similar transformation under the influence of very active chem. agents. Humus cannot be always identical in its chem. compn.

W. H. FAY.

The nitrifying powers of soils as indices to their fertility. C. B. LIPMAN. *Proc. Soc. Prom. Agr. Sci.* 35, 73-9(1914); through *Expt. Sta. Record* 34, 218(1916).—It is concluded that the nitrifying power of a soil is one of the prime factors in detg. its productive power. W. H. FRY.

The physiology and distribution of denitrifying thiosulfate bacteria. A. GEHRING. *Centr. Bakt. Parasitenk., Abt. II* 42, 402-38(1915); *Expt. Sta. Record* 33, 23-4.—After briefly reviewing the work of others bearing on the subject, G. reports the results of his studies on the physiology and distribution in soils of the anaerobic denitrifying S bacteria found by Lieske (cf. *C. A.* 9, 640). These bacteria were found in various silty soils, in composts, cultivated soils, forest soils and peats. The numbers were constant at different depths in peat and cultivation soil, but varied greatly in the different soils examd., increasing with an increasing C content. Those found in cultivated soil were only about $\frac{1}{4}$ as powerful in their action as those in the compost, forest soil and peat; G. thus distinguishes two races. Nitrate decompn. increased both in the soil and in nutritive soln. with increasing thiosulfate and nitrate supply. The nitrate could not be replaced by other compds. as source of O, nor could the thiosulfate be replaced by S-free compds. as the energy source for the bacteria in question, although other S compds. could be substituted. Carbonate and bicarbonate were equally effective in supplying the C. Through the addition of thiosulfate to the soil, a strong denitrifying action was induced, not as strong, however, as that brought about by the addition of organic matter. An addition of bicarbonate also increased the denitrification in the soil. G. believes his expts. explain many of the results obtained by Thalau on the influence of sulfites, thiosulfate and S on vegetation. C. F. MILLER.

Antagonism between anions as affecting soil bacteria. III. N fixation. C. B. LIPMAN AND P. S. BURGESS. *Centr. Bakt. Parasitenk.* 42, 502-9(1915).—This is one of a series of articles (cf. *C. A.* 9, 499, 1649, 2281) pertaining to the influence of alkali salts on the natural bacterial flora of the soil. The following conclusions are drawn from the investigation in which a light, sandy soil was used: "Very slight, perhaps questionable, antagonism between anions occurs for the nitrogen-fixing flora of the sandy soil used when Na_2CO_3 and NaCl are mixed, whether one or the other is used as a const. factor. The same is true when NaCl and Na_2SO_4 are combined provided the first named salt is the const. toxic factor. It is not true when Na_2SO_4 is used as the const. toxic factor. No antagonism obtains between Na_2CO_3 and Na_2SO_4 , no matter how the salts are combined and no matter which of them is used as the const. toxic factor. The concns. at which N fixation ceases are lower when the salts are mixed than when they are used singly. The N-fixing flora differ totally in respect to antagonism between anions from the ammonifying and the nitrifying flora of the same soil. The resistance of these N-fixing flora, however, to salt effects is far greater than that of the other flora named." C. F. MILLER.

The fixation of potash by soil bacteria. S. KYROPOULOS. Univ. Göttingen. *Z. Gärungsphysiol.* 5, 161-6(1915).—The examn. of soil cultures under varying conditions for the growth of soil bacteria, with the addition of varying amts. of potash, gave no analytical evidence of the fixation of appreciable amts. of potash by the bacteria. This finding was confirmed by analytical detns. on liquid cultures. A. W. DOX.

Investigations on the absorption of ammonia by the soil. L. PINNER. *Kühn Archiv.* 6, 153-238(1915).—After giving a rather exhaustive critical discussion of the literature on the subject of absorption, P. reports the results of expts. he carried out to det. the absorptive power of soils for NH_3 . Fourteen soils of various textures and taken from widely separated localities were used in the work and in each case, the NH_3 absorbed was detd. by 2 distinct methods which yielded fairly concordant results. Although

no relation was found to exist between either the mechanical or chem. compn. of the soil and the absorption values, the hygroscopic capacity of related soils varied directly with the amt. of gas absorbed. The soils absorbed from 10 to 38 cc. of NH_3 per g. Isotherms constructed from the absorption values of NH_3 by soils resemble those obtained with charcoal and the same gas. The gas was absorbed to a great extent under low pressure, the increase becoming less and less with rise of pressure. While the greater part of the gas was taken up in a few minutes, a stationary condition was reached only after several hrs. Although the absorption of soils still containing hygroscopic moisture was greater than that of the dried material, it was not as great as the sum of the absorption values of the dried soil and water. The greater part of the gas was lost shortly after the soils were removed from the NH_3 atm., but a considerable part (one-tenth of the total) was retained after 24 hrs. exposure to the air and also after the soil was heated at 105° for 4 hrs. Only a loose relationship was found to exist between the NH_3 absorbed from solns. of NH_4Cl and NH_4OH even when similar soils were compared. The writer concludes that it is very difficult to formulate a theory generally applicable to absorption phenomena in soils because of the large number of factors involved. He believes the surface-tension theory of Freundlich offers the best explanation.

C. F. MILLER.

The nitric nitrogen of the black soils of the arid regions of Russia. N. M. TOULAIKOV. *Besentchuck Agr. Expt. Sta., Selskoye Khosiaistvo Liesovodstvo* 247, 35-65 (1915); through *Bull. Agr. Intell.* 6, 797-9(1915).—Nitrification is studied in relation to seasons, cultural methods, manuring, and crops.

W. H. FRY.

Studies in the drying of soils. M. A. KLEIN. *J. Amer. Soc. Agron.* 7, 49-77 (1915); *Expt. Sta. Record* 33, 810.—The object of this investigation is to study the effect of drying the soil on its chem. and biological condition and on plant growth. Two soils were used in this study, one low and one high in organic content. It is shown that drying a soil previous to planting has a beneficial effect on plant growth. The factor which causes this beneficial effect is influenced by the organic matter in the soil. H_2O -sol. matter is increased in the soil of low organic content while the opposite is true with the soil of high organic matter. The drying of the soil had little effect on the available K, Ca, or P in the soil. The bacterial activity as measured by the CO_2 production is increased by a previous drying of the soil. The CO_2 production is very low in the dry soil, ceasing after 7 days. The soil kept moist for 35 days after drying assumes its normal condition. The nitrifying power of the soil was increased by a previous drying. The dry soil showed a reduction in NO_3 as in the CO_2 production.

J. J. SKINNER.

Chemical and biological notes on cherry orchard soils. A. HARVEY AND C. H. HOOPER. *The Gardeners Chronicle* 57, 308-9(1915); *Bull. Agr. Intelligence* 6, 1067.—The investigation was made to det. the difference between those soils which are known to be favorable and those which are unfavorable to the growth of cherries. The poor soils were somewhat lower in plant food, especially K. These differences were small. The chem. analysis points to no particular feature. It is concluded that pollination had more influence in fruit production than the soil.

J. J. SKINNER.

Weathering in the podzol soils from central Norrland. OLOF TAMM. *Bull. Geol. Inst. Univ. Upsala* 13, 183-204(1915).—From a detailed chem. study of the rocks, soils, and humus substances of this region, the following conclusions are drawn: (1) The chem. compn. of unweathered soils in central Norrland (with the possible exception of clays, which were not examd.) appears to be very uniform. (2) The chem. and mineralogical character of layers weathered by the action of humus (Rohhumus), known as bleached-earth (Bleicherde) are also very much alike, when the occurrences

are typical. (3) The chem. processes which are active in the weathering by humus may comprize soln., but not transformation of the minerals. Apatite and the dark minerals such as biotite and hornblende are the most readily sol.; the feldspars are attacked only to a quantitatively unimportant extent. Kaolinization could not be demonstrated, even where the feldspars were relatively strongly attacked. (4) An estimation of the magnitude of the change of the original material in the process of bleached-earth formation shows that about 7.5% of the original bases are dissolved.

E. T. WHERRY.

Experimental data on podzol formation. V. P. SMIRNOV. *Esheg. Geol. i Min. Rossi* 14, 206-10(1912); *Zhur. Opytn. Agron.* 15, 228-9(1914); through *Expt. Sta. Record* 33, 814(1915).—In expts. with a sandy podzol soil 2 glass tubes 5 cm. in diam. were filled with the soil in its natural stratification, and distd. water, distd. water containing CO_2 , and a soln. of NH_3 were allowed to percolate through the soil for 24 hrs. The filtrates contained different amts. of leached-out org. and inorg. constituents, the smallest amt. being in the distd. water containing CO_2 and the most in the NH_3 soln. These results, together with preliminary analyses of the soil layers, led to the conclusion that the cementing material of the subhorizons of podzol soil consists of org. matter and colloidal silica. In the tube treated with NH_3 a brown ring appeared between the lower subhorizon and the subsoil, which is thought to be an orstein formation.

W. H. FRY.

Red soils and phosphatic manuring in the state of Sao Paulo, Brazil. J. ARRÊ. "Luiz de Queiroz" College. *Boletim agricultura*, Series 15, 535-55(1914); through *Bull. Agr. Intell.* 6, 1042-4(1915).—Soil analyses and expts. upon the absorptive capacities of red soils for P_2O_5 are given.

W. H. FRY.

The fertilizer requirements of the soil. F. MÜLLER. *Landw. Jahrb. Schweiz.* 29, 119-34(1915).—M. has compiled tables showing how the numerous expts. carried out in Switzerland during the past 20 years, support the principle of Wagner according to which the compn. of the first hay cutting is used as an indication of the fertilizer requirement of the soil. Wagner found that the hay should contain 2% K_2O and 0.7% P_2O_5 ; if it contains less of either, the soil is deficient while if it contains more there is already an excess present. It is stated that this method of detg. the needs of a soil gives much more consistent as well as more significant results than the parallel plot method.

C. F. MILLER.

Seaweed as a source of potash for agriculture. A. A. MOFFATT. *Trans. Highland Agr. Soc. Scotland* [5] 27, 281-6(1915); *Expt. Sta. Record* 34, 26.—Seaweed from the coast of Ireland and Scotland contains in its fresh state about 80% moisture. Three methods of treatment to utilize it as a fertilizer are described. Burning the seaweed to a loose ash is the most practical method. More K from a given quantity of seaweed is secured by carbonizing the air-dry material in retorts or ovens. By this method the substance swells and forms a porous charcoal from which the salts can be readily dissolved. A number of by-products are obtained; the NH_3 is recovered as $(\text{NH}_4)_2\text{SO}_4$ from the H_2O used for purifying the gas by-products.

J. J. SKINNER.

Composition and use of certain seaweeds. JAMES HENDRICK. *J. Board Agr.* 22, 1095-1107(1916).—Attention is called to the shortage of potash due to the supply from Germany being cut off. K and I have long been obtained from kelps of Scotland and the U. S. has pointed out recently the high K content of Pacific coast kelps. Analyses are given of seaweeds of *Fucus* and *Laminaria*. The stems in all cases contained more K than the fronds and less I on the average, and *Laminaria* was much richer than *Fucus*. Dried *Fucus* contained on the average 3-4% K_2O ; *Laminaria*, 10%. None

of these weeds carries as much K as the Pacific coast kelps. A few varieties of seaweed are used as stock food and occasionally as human food. R. O. E. D.

Notes on the chemical composition of karroo ash. CHARLES F. JURITZ. *S. African J. Sci.* 12, 133-42(1915).—Karoo ash (burned sheep manure) has an av. compn. of 9.85 K₂O, 21.81 CaO and 2.86% P₂O₅. A table of analyses of the unburned manure is added. W. H. FRY.

Rock phosphate in New Zealand. B. C. ASTON. *J. Agr.* 10, 495-509(1915); *Bull. Agr. Intell.* 6, 1460-2.—The most important deposits recorded are at Milburn, Otayo and on Bounty and Antipodes Islands. J. J. S.

The utilization of coffee pulp as fertilizer for tropical crops. R. D. ANSTAD. *Tropical Life* 11, 124-6(1915); *Bull. Agr. Intell.* 6, 1457-8.—Waste from coffee products on coffee farms furnishes a good fertilizer when composted and when leaching is prevented. It was used to advantage as a bedding for cattle. Dry coffee pulp contains about 85% org. matter, 0.8 P₂O₅, 2.4 K₂O, 0.6 CaO and 2.6 N. As a fertilizer it was improved by reinforcing with bone meal or P₂O₅. J. J. SKINNER.

The cultivation of seaweed in Ireland and its use as fertilizer. G. H. PETHY-BRIDGE. *J. Dept. Agr. Tech. Instruction for Ireland* 15, 546-9(1915).—Two classes of seaweeds are used as fertilizers in Ireland, the first belonging to genus *Laminaria* which grow in deep water, and the second to genus *Fucus* whose habitat is between tide marks. By the cultivation of seaweed "is meant the provision of suitable anchorages, generally large stones, in localities where these are naturally absent." It is stated that the weeds are only used locally by the farmers owning the beds and are seldom sold. No analytical data are given. C. F. MILLER.

The production of phosphate rock in 1914. W. C. PHALEN. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 41-56. E. J. C.

The solubility of the phosphoric acid of basic slag in water saturated with carbon dioxide. J. G. MASHAUP. Kijkslandbouw proefstation te Groningen. *Verslagen van Landbouwkundige Onderzoekingen der Kijkslandbouwproefstations* No. 17, 97-135 (1915); through *Bull. Agr. Intell.* 6, 1308-10(1915).—The soly. of P₂O₅ is studied in connection with the ratio slag:water, simultaneously with the soly. of the CaO, continuous extns. being employed. W. H. FRY.

Displacement of potassium and phosphoric acid contained in certain rocks by some substances employed as fertilizers. G. ANDRÉ. *Compt. rend.* 162, 133-6 (1916).—The trituration of glauconite in the presence of water in contact with CaCO₃, NaCl, NaNO₃, (NH₄)₂SO₄, and CaSO₄ liberated quantities of K of the same order of magnitude as those given by microcline. NaCl, and especially NaNO₃, had a more energetic effect than they have on feldspar. The action of CaCO₃ and CaSO₄ is more marked than on feldspar. The max. displacement of K was obtained with (NH₄)₂SO₄. Apatite treated somewhat similarly gave negative results with (NH₄)₂CO₃ and nitrates. On the other hand, K₂CO₃ displaced a certain amt. of P₂O₅. W. H. FRY.

Speed of solution of compounds of potassium, aluminum, and iron of natural phosphates by mineral acids. I. A. V. KAZAKOV. *Is Resul't. Veget. Opytov. Lab. Rabot* 9, 21-45(1913); *Expt. Sta. Record* 34, 220(1916).—A review of the fundamental principles underlying the speed of chem. phenomena in general and of the soln. of solids in particular and a review of the literature bearing on the subject are followed by a report of expts. to det. the role of concn. of the solvent, duration of the reaction, degree of pulverization of the phosphate, preliminary roasting of the phosphate, and rapidity of introducing the solvent on the speed of dissolution of K, Al, and Fe of 4 differ-

ent natural phosphates. The solvents used in different concns. were H_2SO_4 , HCl , and H_3PO_4 . The results are graphically reported. W. H. FRY.

Mechanical enrichment of natural phosphates in calcium phosphate. A. V. KAZAKOV. *Is Resul't. Veget. Opylov Lab. Rabot* 9, 46-56(1913); *Expt. Sta. Record* 34, 220-1(1916).—Expts. on 6 series of typical natural phosphates are reported, the object of which was to det. the effect of grinding and sifting into 2 fractions and of roasting on the P_2O_5 content of the 2 fractions. The phosphates were ground to a size of 0.5 mm. or less in diameter and were sifted into 2 fractions, below and above 0.08 mm. The greatest difference in P_2O_5 content of the 2 fractions was obtained with the first phosphate series, containing an av. of 16% P_2O_5 ; the fine-grained fraction contained 24% P_2O_5 and the coarse-grained fraction 13%. Another series showed only a small difference, and a 3rd series no difference. The 6th sample, containing from 26 to 27% phosphate, showed results opposite to those obtained with the first sample, the coarse-grained fraction being the richer in P_2O_5 . The theory underlying this phenomenon is explained. After a preliminary roasting of the first series of phosphates it was found that the fine fraction contained the more P_2O_5 . W. H. FRY.

Preparation of the phosphate extracted by sulfurous acid from Viatka phosphate. V. P. КОЩЕТКОВ. *Is Resul't. Veget. Opylov Lab. Rabot* 9, 1-20(1913); *Expt. Sta. Record* 34, 220(1916).—These expts. of the dissolving tests of the included action of H_2SO_3 on the P_2O_5 of phosphorite and the pptn. of the H_2SO_3 soln. by (1) evapn. of the soln. to dryness, (2) elimination of excess SO_2 by boiling, (3) pptn. of the phosphate with lime. It was found that passing a current of SO_2 through phosphate suspended in water almost completely dissolved the P_2O_5 . The addition of H_2SO_4 to the water in an amount hardly sufficient to decompose the CaCO_3 of the natural phosphate was found to increase the dissolving power of H_2SO_3 for P_2O_5 . After evapn. to dryness the residues contained from 22 to 24% of P_2O_5 , of which 57 to 80% was sol. in citric acid. Boiling the soln. resulted in the pptn. of about half of the phosphate dissolved, which contained from 23 to 36% P_2O_5 . The other half of the dissolved phosphate was pptd. by milk of lime, the product containing from 16 to 26.5% P_2O_5 , of which from 86 to 94% was sol. in citric acid. W. H. FRY.

Sewage sludge as fertilizer. ANON. *J. Bd. Agr.* 22, 235-8; *Bull. Agr. Intell.* 6, 1033-6(1915).—The article briefly reviews the results of expts. carried out by various investigators in different parts of England to det. the value of sewage sludge as a fertilizer. Expts. at Rothamsted showed that removal of the grease does not increase the ease of decompn. Most of the expts. lead to the conclusion that the N and P_2O_5 in the sludge are present in a non-available form, and it is suggested that in the future attention should be directed to methods of rendering the sludge more available to plants. C. F. MILLER.

A new method of preserving liquid manure. SCHMOEGGER. *Westpreussische Landw. Mitt.* 20, 34(1915); *Bull. Agr. Intelligence* 6, 1308.—The process is based on the principle that lactic acid bacteria are able to develop in liquid manure and preserve it if a certain amount of sugar be present. For the preservation of 100 tons of liquid manure, 0.5 ton of sugar is needed (3.1 tons of sugar beets). The ferment, which is used to a large extent in Germany for preserving potatoes, is *Bacillus cucumeris fermentati*. Expts. are being carried out on farms to det. the practicability of the method. C. F. MILLER.

Composition of liquid manure as shown by agricultural investigations in southern Switzerland. C. DUSSEKRE. *Ann. agr. Suisse* 16, 83-8(1915); through *Expt. Sta. Record* 34, 24(1916).—The average of 23 analyses of typical liquid manure shows that

the fertilizing elements are present in the proportion of 100 parts N to 285 parts K to 4 parts P_2O_5 .
W. H. FRY.

The composition and value of liquid manure. J. HENDRICK. *North of Scotland Col. Agr. Bull.* 19, 29 pp. (1915); through *Expt. Sta. Record* 34, 23 (1916).—The results of analyses of 35 samples give an av. compn. as follows: water 98.21, solids 1.79, total N 0.204, ammoniacal N 0.179, P_2O_5 0.029, K_2O 0.462, CaO 0.019%. Field expts. on hay land and clover are reported.
W. H. FRY.

External and internal phases of the action of attenuated acid gases and smoke on plants. H. WISLICHENUS. *Mitt. Sachs. Forstl. Versuchsanst. Tharandt* 1, 85–175 (1914); *Expt. Sta. Record* 33, 629.—This article reports the results obtained by repetition under more favorable conditions (cf. C. A. 9, 2961) of former expts. and also of later work to det. the influence on vegetation of gases at great dilns. Very dil. H_2SO_4 was found to be markedly injurious only when the leaves or needles of the plants were assimilating, the extent of the injury being proportional to this activity. Light intensity and assimilating activity are the principle conditions influencing the action but others are discussed as modifying factors.
C. F. MILLER.

The influence of radioactive earth on plant growth and crop production. H. H. RUSBY. *N. Y. Bot. Garden* 16, 1–23 (1915); *Bull. Agr. Intelligence* 6, 1318–9.—Expts. were made with radioactive material supplied by a producing company. The material as tested consisted of the powdered rock, after the extn. of radium, mixed with an ordinary fertilizer. The compn. of the fertilizer used is not given. Good results were secured by the mixt., which caused increased production of given house plants, garden vegetables and field crops.
J. J. SKINNER.

A new dipping fluid. J. C. BRÜNNICH AND F. SMITH. *Queensland Agr. J.* 3, 161–3 (1915); *Bull. Agr. Intell.* 6, 1071–2.—The investigation was made to secure a substitute for tallow and tar in As dipping fluids. Bone oil, a by-product in the manuf. of bone charcoal was found to be suitable. It is readily emulsified by boiling with alkali. Spraying expts. against ticks with bone oil at the rate of 1 gal. to 400 gals. of As soln. proved efficient. The bone oil is heated with $\frac{1}{4}$ its weight of NaOH. After 15 min. a dry mixt. of As and NaOH is stirred into the oil in small portions. On cooling H_2O is added.
J. J. SKINNER.

The addition of soft soap to lead arsenate for spraying purposes. D. R. EDWARDES-KER. *J. Southeast. Agr. Col. Wye* 1913, 359–62; *Expt. Sta. Record* 33, 538.—The methods of prepg. solns. of soft soap and lead arsenate suspensions were studied. The addition of 1% soap soln. to lead arsenate does not cause an appreciable increase in the amt. of sol. As. H_2O was best used to make up the solns. of $Pb(CH_3CO_2)_2$ and Na_2HAsO_4 when homemade soap solns. are used.
J. J. SKINNER.

Composition of rainfall at Montevideo (SCHROEDER) 14.

Phosphates. E. STOPPANI and V. VOLPATO. *Brit.*, 100,034, Jan. 21, 1916. Natural phosphates are ground and mixed with 6% or more of an alkali or alk.-earth oxide, carbonate, sulfate, or other salt, the mixt. being calcined but not fused, a temp. of 600° being mentioned. The material is hydrated, preferably while still hot, by adding H_2O . The product is assimilable by plants; it is sol. in organic acids.

Emptying superphosphate chambers. H. W. HALL. *Brit.*, 22,645, Nov. 17, 1914. A superphosphate chamber is made of Fe with a thin lining of masonry, prepared wood, or dried superphosphate, and is arranged on tilting bearings so that it can be set in inclined positions to allow the advance and return movements of the motor-

driven rotary cutter to be effected by gravity. The rails are disposed out of reach of the cut superphosphate, and a gas exit is provided. The cutting machine is transported to other chambers by a trolley on rails. If there is room behind the chamber, the cutting machine may leave the chamber without reversing its direction.

16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

History of brandy. P. MARTELL. *Z. Spiritusind.* 39, 77(1916).—A short review. L. W. HAAS.

Determination of total tartaric acid as well as the alkaline earth tartrates, potassium hydrogen tartrate and free tartaric acid in wine. R. KUNZ. *Arch. Chem. Mikros.* 8, 51-61(1915).—The method is based on the peculiar fact (which K. is not yet able to explain) that tartaric acid may be completely pptd. as K H tartrate by means of EtOH in the presence of excess of KCl and a certain amt. of free HCl. *Total tartaric acid:* Evap. 50 cc. of wine in a porcelain dish after addition of exactly 3 cc. 0.5 N HCl and 2 cc. 20% KCl soln. to 10 cc. on a water bath, add 100 cc. 96% (by vol.) alc. under violent stirring and let stand for 12 hrs., filter, wash ppt. thoroughly with alc., return ppt. to dish, dissolve in hot water and titrate with 0.1 N NaOH as usual. *Potassium hydrogen tartrate:* Evap. 50 cc. of wine in a weighed dish to exactly 10 g., add 100 cc. of 96% alc. and continue as above. *Free tartaric acid:* To the total filtrate from the K H tartrate detn. (in an Erlenmeyer) add 2 cc. 20% KCl soln. and mix well; after 12 hrs. add exactly 2 cc. 0.5 N HCl, filter and treat ppt. as under total tartaric acid. *Alk. earth tartrates:* Total tartaric acid minus the sum of K H tartrate and free tartaric acid gives the amt. of tartaric acid, which must be taken as combined with the alk. earths. The method is shown to give trustworthy results even in the presence of larger quantities of free malic, lactic and succinic acids and especially of K H malate.

L. W. HAAS.

The colorimetric determination of pentoses and methylpentoses in wine. F. SCHAFFER. *Mitt. Lebensm. Hyg.* 6, 163-7(1915).—S. mentioned in a previous article (cf. C. A. 9, 1364) the value of the detn. of pentoses and Me-pentoses in wine analysis, and that these could be detd. colorimetrically. A wine containing more than 3% of sugars must be fermented 2-3 days after diln. with 2 or 3 vols. of H₂O before detg. the pentoses and Me-pentoses, but in dry wines they can be detd. without further treatment. 100 cc. of the sample are concd. to 35 cc., the residue made up to 50 cc. with water, 22 cc. of pure, concd. HCl (d. 1.19) added, and refluxed under a well cooled condenser 2 hrs., then made up to 100 cc. with H₂O, and as rapidly as possible 92-93 cc. distd. off. (Cork stoppers must be avoided.) The distillate is dild. to 100 cc. with water, and 5 cc. taken for the following colorimetric test: To 5 cc. of the soln., in a test tube, about 0.2 g. of pure resorcinol and 10 cc. of chem. pure concd. HCl are added, the tube closed with a rubber stopper carrying a 35-cm. air condenser, and after heating in a boiling water bath for 10 min., cooled quickly. The pentosan content is detd. by comparison with standards, made by distg. and treating known amts. of pure arabinose, the same as the sample, or from a soln. of "Papiertrot B. conc. der Chem. Gesel. in Basel." 0.1 g. of this dye dissolved in 1 l. of H₂O, and dild. 7.5 times for use, gives a color equal to 0.1% of pentosans. The methylpentosans (rhamnose) are detd. in a similar manner, using 5 cc. of distillate, a small amt. of vanillin, and 10 cc. of concd. HCl, and heating as for pentosans, but for 5 min. only, then quickly cooling and comparing the blue soln. thus obtained with a standard containing 0.1 g. "Indigo carmine dry powder Merck" dissolved in 1 l. H₂O. For use dil. with 5.5 vols. of H₂O, which gives a color equal to 0.1% of

rhamnose. Both of these standard dye solns. keep well in the dark. Of 200 natural wines none gave a value less than 2 for the factor arabinose/rhamnose. With skin wines and pomace wines, the factor ran from 0.5 to 1.0. H. S. BAILEY.

The practical application of improved methods of fermentation in California wineries during 1913 and 1914. F. T. BIOLETTI AND W. V. CRUESS. *Calif. Sta. Circ.* 140, 14 pp.—Wineries in several districts of the State using the ordinary spontaneous method of fermentation were compared with wineries in the same regions employing small amts. of SO_2 to check wild yeasts, followed by the application of pure selected wine yeast of the "Burgundy" variety. The tests covered 22 wineries for 2 seasons. During the hot fermenting season of 1913, many of the spontaneously fermented wines "stuck" with unfermented sugar, became high in volatile acid, and badly attacked with "tourne" bacteria. Wines in the same districts, made from the same types of grapes and fermented with the pure yeast and SO_2 , were perfectly sound and kept well. The 1914 season was cooler and the spontaneous fermentations were better than in 1913, but still under these favorable conditions the wines fermented by the improved methods gave sounder wines than resulted from the spontaneous fermentations. The volatile acid is used as an index of the stability of a new wine. Av. loss in SO_2 during fermentation was 63.6% of that added. A blend of spontaneously fermented wines increased rapidly in volatile acid when incubated, while a blend of wines made with pure yeast and SO_2 remained practically constant in volatile acid on incubation. W. V. C.

Dealcoholized wine. S. CARROLINI. *Italia agricola* 52, No. 5(1915); through *Bull. Agr. Intell.* 6, 980-2(1915).—A description (with cut) is given of G. Ciapetti's process. The operation of depriving wine of its alc. is carried out in such a way as not to cause loss of any of its other valuable constituents; this is accomplished by a fractional distn. under relatively low pressure. The very small quantities of esters and other compds. which give perfume to wine are sepd. at 25 to 30°, the ethyl alc. is then distd. off at 50 to 55°, after which the flavoring fraction is again mixed with the remaining wine. In this way a wine of less than 1% alc. by vol. is obtained which contains all other components of wine in a slightly increased quantity with the exception perhaps of some of the volatile acids. The lack of these is remedied by the addition of CO_2 , which, together with a small quantity of sugar (about 3%) in the case of a very dry wine, renders it very palatable. Another advantage of this process is that the alc. obtained at low temp. and in partial vacuum is of great purity, being free from higher alcs. L. W. HAAS.

Determination of arsenic in beverages. L. VUAFLART. *Ann. fals.* 8, 414(1915).—The reagent of Bougault (10 g. NaH_2PO_4 dissolved in 10 cc. water, made up to 200 cc. with concd. HCl allowed to settle and decanted) may be employed in the detn. of As in beverages. The manipulation is simple and the sensibility sufficiently delicate to detect one mg. of As per l., using a 250 cc. sample. In the case of beer and wine it is necessary first to separate the As from the larger part of the org. material, to concentrate in a ppt. and to purify the latter. H. A. PIPER.

Soft resins in sulfured and unsulfured hops in cold and in open storage. G. A. RUSSELL. U. S. Dept. Agr., *Bull.* 282, 19 pp.(1915).—A large sample of Californian hops was used for these investigations. The green hops were divided into 2 lots, one of which was sulfured during the drying process. The dry sulfured and unsulfured hops were again divided into lots for analysis and for storage (wrapped in burlap). At the end of the 1st, 2nd and 3rd years samples of the stored hops were analyzed. The following conclusions are drawn: Sulfuring and cold storage retard changes in the physical characteristics of hops; a combination of the 2 factors is more effective than either factor alone. The moisture content of sulfured and unsulfured hops held in cold

storage increased first and then remained practically constant; in open storage it varied according to existing weather conditions. The soft resins diminished from year to year with all samples, the hard resins at the same time increasing and approaching a uniform value at the close of the third year. Both sulfuring and cold storage retarded the decrease in soft resins. The total resins in all samples varied from year to year, and in the third year they became materially less than those of the original sample. The low total is probably due to the formation of products insol. in the solvents used (petroleum ether and Et_2O). The color, odor and taste of the soft resins are of very little value in detg. quality and are not indicative of any changes that may have taken place therein. The acid value in general decreased in the sulfured hops in cold and open storage and increased in the unsulfured hops. The ester value in general increased in all the samples of hops. Sulfuring apparently favors the formation of esters and this factor in combination with open storage appears to be the least effective in retarding the formation of esters. The sapon. value in general increased in all samples. The unsulfured hops showed the least change, especially those held in open storage. The I value in general increased in all samples. It was most pronounced in the 2nd year and in the 3rd year was uniform in all samples. Sulfuring in combination with open storage appears to cause a uniform rate of increase in the I value from year to year. The sulfured hops in open storage showed the least variation in changes in the chem. values of the soft resins. During the period of storage at least some of the components of the soft resins underwent rearrangement, this having been most marked during the first year, after which it decreased to such an extent that thereafter comparable values for the chem. constants were readily obtained.

L. W. HAAS.

Drying of potato slop. G. FORTH. *Z. Spiritusind.* 39, 9-11(1916).—The cost of drying original potato slop is very high. With corn slop of the same concn. the cost is the same, but drying of this is more economical, because dried corn slop has a feed value about double that of dried potato slop. By drying the residue obtained by decantation, filtration and pressing out the total cost of drying may be reduced by 70 to 90%, but this process involves a loss of 45 to 55% of dry substance. F. arrives at the conclusion that the problem to dry potato slop in an economically, satisfactory way is not yet solved and that there is little chance to solve it in the future.

L. W. H.

Coatings for cement vats. W. V. CRUESS. *Calif. Sta. Rept.* 1915, 31.—The tests were made to find a suitable coating for the interior of cement wine tanks. A melted mixt. of equal parts rosin, beeswax, and paraffin gave the best results. Gilsonite applied in soln. in CS_2 or melted with ceresin wax was very satisfactory.

W. V. C.

Extermination of grain pests by "globol." J. F. HOFFMANN. Berlin. *Z. Spiritusind.* 39, 11(1916).—"Globol" is to be employed in the same way as CS_2 and aniline oil, but in slightly larger proportions. "Globol" may be used in liquid ($\text{C}_6\text{H}_5\text{Cl}$) and solid ($p\text{-C}_6\text{H}_4\text{Cl}_2$) form. Liquid "Globol" is more effective than solid "Globol."

L. W. HAAS.

The utilization of waste oranges (CRUESS) 12.

Removing fermentation scum during air-yeast manufacture. R. REIK. Aust., 70,615, Dec. 10, 1915. The scum is drawn off by suction and returned under the surface of the vat liquor.

Removing fermentation scum during air-yeast manufacture. F. WULF AKT-GES. Aust., 70,639, Dec. 10, 1915. The foam is vaporized by blowing into the fermenting and aerated wort, fine, uniformly divided jets of air.

Fermenting tanks. F. ROGERSON. *Brit.*, 22,820, Nov. 20, 1914. A fermenting tun formed of ferroconcrete is lined with damp-proof cement consisting of cement mixed with soapy, greasy, or other waterproof material. The cement described in 17,070 x912, may be used. A second internal lining of a porous cement consisting of cement and sand is applied and is impregnated with a mixt. of waxes to which gums or resins may be added, as a mixt. of beeswax, ceresin, paraffin wax, and carnauba wax. The supports for the attemperator and the sluice or parachute are fixed in the walls of the tun during the construction.

17. PHARMACEUTICAL CHEMISTRY.

M. I. WILBERT.

The determination of the iodine number of essential oils. R. MARCILLÉ. *Ann. fals.* 9, 6-11(1916).—A continuation of the study of the I no. of essential oils, with reference to liquors. (Cf. *C. A.* 9, 1092.) The I no. obtained by the method previously given, and the n_D^{20} for 43 essential oils are tabulated. Tables and curves show the effect of light and the time of reaction upon the I no. of angelica, anise, and peppermint oils. In the dark there is a gradual increase in the I no. up to 18 to 20 hrs., but in the light with angelica a rapid decrease after 15 min., while with anise the max. value is obtained after 45 min., and then the value drops off gradually. Oil of balm-mint, and peppermint, do not reach a max. under 2 hrs., but most of the other essential oils give curves in the light showing a diminution in the I no. after the first 30 min. Among all the oils studied anise and star anise alone show an increase in the I no., due to the action of light, and this property may serve to identify them. Oil of peppermint has an I no. of 0.58, while menthol shows no I absorption. This fact can be used to distinguish them. The I no. of anise oil decreases with the age of the sample, or its oxidation.

H. S. BAILEY.

Evaluation of opium tinctures. P. BOHRISCH AND F. KUERSCHNER. *Apoth. Ztg.* 31, 53-5(1916).—Reference is made to Fromme's comment (cf. Caesar & Loretz Jahresbericht) on a similar investigation by the above authors (cf. *C. A.* 9, 1968). In their opinion, Fromme's suggested Al acetate method offers no material advantages over the modified procedure of the Ger. Pharm., for which the following amended form is favored: Evap. 50 g. opium tincture in a porcelain dish to 15-20 g., dil. with H_2O , to 38 g. and add 2 g. approx. NH_3 . Pass through a folded filter into a glass-stoppered flask. To 32 g. filtrate (=40 g. tincture) add 10 cc. EtOAc and 5 cc. NH_3 and shake 10 min. vigorously, then add 20 cc. EtOAc and agitate moderately. After sepn. into layers, pour the EtOAc as completely as possible on to a smooth 8 cm. filter. After the ethereal liquid has run through, follow with the aq. layer. Should any EtOAc remain on the paper, it may be made to pass through by raising the filter and introducing between it and the glass a few strips of paper. Both flask and filter are washed with five 5 cc. portions H_2O previously satd. with EtOAc. Transfer the moist filter and morphine to a 200 cc. flask, add thereto the morphine remaining in the former flask by dissolving with 25 cc. 0.1 $NHCl$, pouring to main portion and following with 50 cc. wash H_2O . Add 20 cc. Et_2O and 10 drops iodoeosin soln. and titrate with 0.1 $N KOH$, shaking the mixt. vigorously after each addition to the appearance of a faint red. The number of cc. of acid $\times 0.07125$ = the morphine in 100 g. tincture. The standardization of acid with respect to alkali should be effected with the same indicator.

W. O. E.

The disappearance of cyanogen in sweetened preparations of bitter almonds. E. RUPP AND A. HOELZLE. *Univ. Koenigsberg. Arch. Pharm.* 253, 401(1915).—As

is well known from the work of Killiani and E. Fischer, HCN and dextrose react with the formation of nitrile compds. Exactly similar behavior has been noted in the case of KCN and Ba(CN)₂ on dextrose (cf. C. A. 8, 1356), for which reason it is inadvisable to incorporate sugar into any medicinal prepn. containing aq. solns. of bitter almonds. In no case should such preps. be sweetened with fruit juices. W. O. E.

Evaluation of organic silver preparations. J. HERZOG. *Arch. Pharm.* 253, 441-2 (1915).—Reference is had to F. Lehmann's suggestions given under the same caption (C. A. 9, 2125), with which the present writer is in entire accord. W. O. E.

Benzoyl peroxide. L. VANINO AND F. HERZER. *Arch. Pharm.* 253, 426-40 (1915).—A monograph descriptive of methods for prepg. this compd., together with some exptl. data relative to the yields resulting therefrom. A new method for estg. Bz₂O₂ is as follows: Into a small erlenmeyer weight 0.2-0.3 g. pure, dry sample, add 10-15 cc. alc., warm a short time on the H₂O bath until fully dissolved, add an excess of 0.5 N KI soln. (if too dilute, some Bz₂O₂ may be pptd.), render slightly acid, then heat the mixt. 4 min. on the H₂O bath, allow to cool and titrate after 1/2 hr. with freshly standardized Na₂S₂O₄. W. O. E.

The constituents of licorice root and of licorice extract. II. PERCY A. HOUSEMAN. *Am. J. Pharm.* 88, 97-105 (1916); cf. C. A. 7, 534.—The methods for detn. of sugars and crude glycyrrhizin remain unaltered, but sepn. of the glycyrrhizin from the starch and gums is now effected with 75% alc. since 80% alc. ppts., in some cases, a small quantity of glycyrrhizin. H. summarizes results of recent extns. of licorice root with ether, 99% alc., 75% (by vol.) alc., 50% (by vol.) alc., and H₂O. The ether exts. range from 2.9% to 4.9%. Alc. (99%) exts. 4.8% to 7.0%, whereas 95% alc. gave 10.8 to 12.7% (C. A. 7, 534), the results from 99% alc. corresponding more closely to the true amt. of total resins present than do those obtained, with 95% alc. which exts. other materials, such as cane sugar. H. describes a systematic prepn. of cane sugar from the root and identified it by its crystalline form, by its $[\alpha]_D^{20} = 66.3^\circ$ and by analysis. The total yield was about 2% of the root used. The hemolysis test was used for the detection of biologically active saponins. Negative results were obtained with both strong and mild aq. extns. of both the green and dried root, and also with exts. in which dil. alc. up to 50% (by vol.) in strength was employed as solvent. Hemolytically active saponins were extd. from both green and dried root by 75% (by vol.) alc. The biologically active saponins are in the inner bark and not in the outer bark or in the central part of the root. A detailed prepn. of glycyrrhizin (glycyrrhizic acid) from licorice root is given. The soln. of the acid was evapd. to dryness *in vacuo* and crystd. twice from hot glacial AcOH and after standing over potash in a vacuum desiccator, the following av. combustion figures were obtained: C = 58.37%, H = 7.72%, N = 1.09%. A portion of these crystals was crystd. 3 times more from hot glacial AcOH and perfectly colorless crystals obtained which, however, did not crystallize well from 50% alc. Two N estns. made on this product both gave 1.89%. The acid prepd. by this method became brown at 185°, partly melted with frothing at 203 to 205°, dissolved readily in warm H₂O, and gelatinized on cooling. It behaves differently toward H₂SO₄ and Br than glycyrrhizin which has not been crystd. from AcOH since a drop of 2 N H₂SO₄ added to 1 cc. moderately strong aq. soln. of the purified glycyrrhizin produces no immediate ppt. but on standing the liquid becomes opalescent, clearing on warming, and on subsequent cooling a granular ppt. is deposited which redissolves on warming. It absorbs Br in the cold but gives no ppt. Work is now in progress on the oxidation of glycyrrhizic acid with KMnO₄ and HNO₃, and also on the isolation of a yellow dye W. G. GAESSLER

The most important new medicines in 1915. F. ZERNIK. *Z. angew. Chem.* 29, I, 89-92 (1916). E. H.

Review of the therapeutic novelties made known in 1915, including the specialties and proprietary remedies. S. RABOW. Lausanne. *Chem. Ztg.* 40, 145-7, 167-9, 183-5 (1916).—The trade name, curative principle and name of manufacturer are given in most cases. A bibliography of 174 references is appended. A special edition may be ordered from *Chem. Ztg.*, Cöthen, Germany. J. H. MOORE.

Mercury salicylate in oil. ROBERT W. TERRY. *Midland Druggist* 49, 495-6 (1915).—To allay pain in its use in subcutaneous injection, J. L. Wollheim (*N. Y. Med. J.*, July 27, 1912) added "quinine-and-urea-HCl" (m. 70-71°) as anesthetic. A homogeneous mixt. of these with the required anhydrous wool fat, some H₂O and liquid petrolatum is tedious to prepare. Eliminating wool fat, T. mixes the Hg compd. (10.0 g.) with liquid petrolatum sufficient for sirupy consistence, triturates with soln. of the quinine salt (2.0 g.) in H₂O (3.0 g.), alternating small portions of the quinine soln. and oil until all of the former is added and the mixt. is homogeneous; then the remainder of the oil, a total of 100.0 g., is added. This prepn. may be sterilized by heat without apparent decompn. Probably the Hg salt in itself is a sufficient sterilizing agent.

S. WALDBOTT.

Hypochlorite solution for the antiseptic treatment of wounds. F. GOLDBY. *Pharm. J.* 95, 573 (1915); Henry Rodwell, *Pharm. J.* 95, 750 (1915).—G. recommends the following modification of Dakin's 2nd formula (cf. *C. A.* 9, 2943): Dissolve 105 g. dried Na₂CO₃ in 2 l. of H₂O. Triturate 150 g. CaOCl₂ of at least 30% available Cl with 1 l. of H₂O, mix the 2 solns. When the thick mass has thinned, filter and wash to 3.5 l. of total filtrate. Titrate 20 cc. thereof with H₂BO₃ soln. (31 g. in 1 l.), using phenolphthalein. The amt. found is very variable with different batches. Dissolve the calcd. H₂BO₃ varying from 20 to 60 g., in 0.5 l. of H₂O and add it to the prepn. The finished soln. is faintly pink to phenolphthalein and has 2.7 to 2.8% available Cl. For use it is dild. with 6 vols. H₂O. A concd. sample kept for 1 month still showed 2.5% Cl. R. cannot confirm the variation of H₂BO₃ and advocates the use of Dakin's original 2nd formula in which the above amts. of Na₂CO₃ and CaOCl₂ are dissolved each in 1 l. of H₂O.

S. WALDBOTT.

Coal gas residuals and their application (WAGNER) 21.

Therapeutic compounds. FARBW. v. M. L. & B. Brit., 22,828, Nov. 20, 1914. 4'-Hydroxy-3'-carboxy-2-phenylquinoline-3-carboxylic acid is prepd. by heating isatinic acid with *p*-acetosalicylic acid in caustic alk. soln., or by heating *p*-aldehydosalicylic acid with aniline and pyruvic acid in alc. soln. It forms a disodium salt and a diethyl ester. It is intended for medicinal use, particularly in the treatment of arthritis and rheumatic diseases.

Organo-metallic compounds. SOC. ANON. DES ÉTABLISSMENTS POULENC FRÈRES. Brit., 22,521, Nov. 14, 1914. 4-Dimethylaminophenylarsonic acid is nitrated by means of dil. HNO₃ or a nitrate in the presence of dil. H₂SO₄; 1 mol. proportion of HNO₃ gives either 4-dimethylamino-3-nitrophenylarsonic acid, or 4-*N*-methylnitrosoaminophenylarsonic acid, or a mixt. thereof; excess of HNO₃ gives a mixt. of 2 dinitro compds. The 4-dimethylamino-3-nitrophenylarsonic acid on heating with caustic alkali soln. yields 4-hydroxy-3-nitrophenylarsonic acid. The parent substance 4-dimethylaminophenylarsonic acid is obtained by treating dimethylaniline with AsCl₃ and oxidizing the resulting 4-dimethylaminophenylarsonic chloride.

Hydroxytriarylmethanecarboxylic acids. BAYER & Co. Ger., 286,433, July 4, 1914. Mixts. of 2 mols. of an aromatic *o*-hydroxycarboxylic acid and 1 mol. of an aromatic aldehyde are treated with ZnCl₂ in the presence of POCl₃.

2-Chloro-4-dimethylaminobenzene-1-arsonic acid. C. F. BOEHRINGER & SÖHNE. Ger. 286,546, Feb. 4, 1915. $m\text{-ClC}_6\text{H}_4\text{NMe}_2$ is treated with AsCl_3 and the resulting arsenoxide is oxidized to 2-Cl-4-dimethylaminobenzene-1-arsonic acid. This acid is less poisonous, and more active, than the corresponding non-chlorinated acid.

Ether-like derivatives of barbituric acid. CHEM. WERKE VORM. H. BYK. Ger. 285,636, Sept. 17, 1912. Alkylalkoxyalkyl- or dialkoxyalkylmalonic acids or their derivs. are converted into the corresponding C,C-alkylalkoxyalkyl- or dialkoxyalkylbarbituric acids by the methods usual for the production of barbituric acids or their C-mono- and dialkylsubstitution products.

Acetic acid. FARBW. v. M. L. & B. Ger., 286,400, Apr. 27, 1913. See Brit., 10,377 (C. A. 9, 2796).

Dihydric phenols. C. F. BOEHRINGER & SÖHNE. Ger., 286,266, Mar. 20, 1912. Addition to 284,533 (C. A. 10, 94). The process of 284,533, addition to 269,544 (C. A. 8, 2221) for the production of dihydric phenols and their substitution products is modified by substituting alk.-earth hydroxide for the alkali hydroxide or carbonate, wholly or in part.

Bismethylhydrazinotetraminoarsenobenzene. C. F. BOEHRINGER & SÖHNE. Ger., 285,573, Dec. 12, 1912. 3,5-Dinitro-4-methylnitroaminobenzene-1-arsonic acid is subjected to a mild reduction (at 50° or less) by means of SnCl_2 and HCl .

Derivative of thebaine. M. FREUND and E. SPYER. Ger., 286,431, May 15, 1914. Thebaine, treated in acid soln. with H_2O_2 or $\text{K}_2\text{Cr}_2\text{O}_7$, yields a compd. of the compn. $\text{C}_{18}\text{H}_{19}\text{NO}_4$, m. 274° , in which the O atom has entered the nucleus. The base yields salts which crystallize well.

6-Nitro-3-amino-1-hydroxybenzene and its methyl ether. FARBW. v. M. L. & B. Ger., 285,638, May 5, 1914. 4-Nitro-1-acetylaminobenzene-3-sulfonic acid (nitroacetylmetanilic acid) is heated with MeOH -alkali under pressure and at elevated temps.

Aluminium ethylate. FARBW. v. M. L. & B. Ger., 286,596, Dec. 13, 1913. Pure Al ethylate is obtained from Al and anhydrous alc. with a good yield if, in the presence or absence of halogen alkyls or I, very small amts. of HgCl_2 are added as catalyst. Upon subsequent vacuum distn., for the purpose of purifying the crude product, the Al ethylate goes over readily and without bumping, solidifying to a snow-white mass, while Hg is not carried over with it.

Methyl chloride. A. HOCHSTETTER. Aust. (app.) 9,887, Feb. 20, 1913. COCl_2 is allowed to act on CH_4 at an elevated temp., and the mixt. is conducted over catalyzers which either act as Cl carriers, or hasten the reaction by surface action.

Methyl chloride from methane. H. HOCHSTETTER. Aust., 70,733, Dec. 27, 1915. COCl_2 is allowed to act on CH_4 at an elevated temp. In a modification, the mixt. of COCl_2 and CH_4 is conducted over catalyzers which function as Cl carriers or hasten the reaction by surface action.

Stable compounds of hydrogen peroxide with organic compounds. CHEM. FABRIK GEDRON RICHTER. Aust., 70,938, Jan. 10, 1916. In the stabilization of the unstable compds. of H_2O_2 with organic substances, according to 26,829, employing as stabilizing agents derivs. of organic acids which, in the presence of alkali, are decomposed with the combination of the alkali with the acid residue. E. g., the compd. of H_2O_2 and carbamide is mixed, while still moist, with 0.5% "urea citric acid," and carefully dried. Other additions are: succinic acid 0.5%, phenacetin 0.3%, alc. soln., Me phthalate 0.5% (dissolved in alc.). Cf. C. A. 10, 1079.

Amino acid esters. R. WOLFFENSTEIN. Aust., 70,829, Dec. 27, 1915. Trichlorotertiarybutyl haloacetates are condensed with secondary aliphatic amines.

Urea. BADISCHE. Aust., 70,830, Dec. 27, 1915. Urea is recovered from the reaction mixts. obtained by heating NH_4 carbonate, carbamate, and the like, by subjecting such mixts. to distn. at temps. not exceeding 80° . The recovery of the NH_3 - CO_2 mixt. passing over during distn. and failing to yield urea, is effected by conducting the NH_4 carbamate and carbonate into an indifferent liquid not miscible with H_2O .

Salts of betaine. AKT.-GES. FÜR ANILIN-FABRIKATION. Aust., 70,874, Jan. 10, 1916. $\text{Me}_2\text{NCH}_2\text{CO}_2\text{Me}$ is brought into reaction with a methyl halide in the absence or presence of an indifferent solvent, and the resulting methyl ester of the corresponding betaine salt is hydrolyzed by heating the aq. soln., preferably in the presence of a mineral acid.

18. ACIDS, ALKALIES, SALTS AND SUNDRIES.

T. LYNTON BRIGGS.

Sulfur, pyrite, and sulfuric acid in 1914. W. C. PHALEN. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 131-49 (separate, published July 26, 1915).

E. J. C.

The production of salt, bromine and calcium chloride in 1914. W. C. PHALEN. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 291-306 (separate, published Sept. 20, 1915).

E. J. C.

The production of barytes in 1914. JAMES M. HILL. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 61-5.—The production of crude barytes in the U. S. in 1914 was 51,500 short tons. Sources are given.

E. J. C.

The production of borax in 1914. CHAS. G. YALE AND HOYT S. GALE. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 285-90 (separate, published Sept. 4, 1915).

E. J. C.

The gypsum industry in 1914. G. F. LOUGHLIN. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 261-70 (separate, published Aug. 23, 1915).

E. J. C.

The production of magnesite in 1914. CHAS. G. YALE. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 569-86 (separate, published Oct. 28, 1915).

E. J. C.

The production of fullers' earth in 1914. JEFFERSON MIDDLETON. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 35-40.—40,981 short tons were produced in 1914.

E. J. C.

The production of fluorspar in 1914 with a note on cryolite. ERNEST F. BURCHARD. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 123-9 (separate, published July 26, 1915).

E. J. C.

The production of feldspar in 1914. FRANK J. KATZ. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 449-54 (separate, published Oct. 15, 1915).

E. J. C.

Arsenic. FRANK L. HESS. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. I, 553-64 (separate 26, published Feb. 26, 1916).

E. J. C.

The production of talc and soapstone in 1914. J. S. DILLER. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 151-7 (separate, published July 30, 1915).

E. J. C.

The production of graphite in 1914. EDSON S. BASTIN. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 159-74 (separate, published Aug. 20, 1915).

E. J. C.

The production of asbestos in 1914. J. S. DILLER. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 93-102 (separate, published July 20, 1915).

E. J. C.

The production of abrasive materials in 1914. FRANK J. KATZ. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 349-68 (separate, published Oct. 26, 1915).

E. J. C.

Results of the new processes for the production of chemically pure nitrogen from the air, also of water gas by a continuous treatment through utilization of the oxygen and decomposition of water vapor by red hot coal. R. PICTET. *Arch. de Genève* 39, 281-4(1915); *Beiblätter Ann. Physik* 39, 474.—The process, which is commercially profitable, rests on the cascade principle.

L. W. RIGGS.

The chemical industries of Germany and France according to French information. H. GROSSMANN. *Chem. Ztg.* 40, 181-3, 222-3(1916).—A review of French statistics as published by Fleurent.

J. H. MOORE.

High-temperature insulation. P. A. BOECK. N. Y. *J. Ind. Eng. Chem.* 8, 372-7 (1916).—Thermal insulation, especially of large furnaces, is discussed, covering some of the ground already covered in *C. A.* 9, 2572; 10, 722.

W. P. WHITE.

The manufacture of plastic masses from casein, especially of galalith. E. STICH. *Kunststoffe* 5, 145-6, 158-61, 171-3, 185-6(1915).—A comprehensive review.

F. W. SMITHER.

The American chemist and the war's problems. JAMES R. WITHEROW. *J. Ind. Eng. Chem.* 8, 453-6(1916).—An address.

E. J. C.

War chemistry. A. TSCHIRCH. *Pharm. Post* 59, 1-6, 17-9(1916).—A review of some of the chem. industries that have been stimulated by the war.

C. O. E.

The influence of the first year of the war upon the price of American chemicals. H. G. *Chem. Ind.* 38, 481-2(1915).

F. W. SMITHER.

Sulfide of phosphorus. F. C. FRARY. *Can.*, 165,931, Nov. 9, 1915. See U. S. 1,153,054 (*C. A.* 9, 2800).

Anhydrous hyposulfite. OESTERREICHISCHER VEREIN FÜR CHEM. UND METALLURGISCHE PRODUKTION. *Aust.*, 70,949, Jan. 10, 1916. The dehydration of solid hyposulfite hydrate is carried on under a high boiling liquid, not miscible with H_2O , at a temp. above the b. p. of H_2O .

Table salt from rock salt. GEWERKSCHAFT EINIGKEIT I. *Aust.*, 70,947, Jan. 10, 1916. An app. comprises a channel, divided in the direction of the motion of the salt into canals, and heated on the bottom.

Sodium oxalate. K. HAUPT. *Ger.*, 286,461, Sept. 19, 1913. Na is fused with 0.1 its wt. of petroleum in the vessel g, provided with reflux condenser e, and heated to 150-200°. CO_2 is then conducted through the tube a at a temp. of 360-400° and under 0.5 atm. pressure, whereby the Na is atomized, by injection, through the tube r, provided with cock b, into the chamber in which the resulting $Na_2(OCO)_2$

falls to the bottom. The excess CO_2 escapes through the valve *f* to be returned to the system.

Zinc sulfate. H. T. DURANT and METALS EXTRACTION CORPORATION. Brit., 21,737, 1914. ZnSO_4 is obtained from roasted ZnS ores by dissolving out the ZnSO_4 with H_2O , if desired, and treating the residue, or the roasted ore without such preliminary treatment, with dil. H_2SO_4 in quantity less than sufficient to dissolve all the ZnO , thus obtaining a soln. free from Fe and SiO_2 . The residue is then treated with more dil. acid to ext. the remainder of the Zn, and this soln., which may be impure, is then used, together with more dil. acid, in the treatment of another batch of roasted ore in which the excess of ZnO ppts. the impurities. The ore before or after roasting is crushed and screened, the coarse part being treated by leaching, and the fine by pulping and filter-pressing.

Heating by chemical action. W. F. McNABB. Brit., 22,242, Nov. 9, 1914. A mixt. for producing heat by chem. action with H_2O consists of a caustic alkali in solid form such as KOH or NaOH, with an oxidizable substance such as $(\text{HOCO})_2$ or tartaric acid, and an oxidizing agent such as a persulfate. The mixt. may be used for warming food in an air-tight can, as a disinfectant, and for cleaning sewers and sanitary appliances. Suitable proportions are 15 g. NaOH, 5 g. $\text{H}_2\text{C}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$, and 5 g. $\text{K}_2\text{S}_2\text{O}_8$ to which 0.5 g. KNO_3 and 3 g. tartaric acid may be added, and, in order to produce greater heat, 0.5 of finely divided or granulated Al. When used as a disinfectant, 0.3 g. of HgCl_2 may be added, together with vanilla, musk, or camphor.

Metal polishes. H. HUNTER. Brit., 22,752, Nov. 19, 1914. A metal polish consists of 1.25 lb. rottenstone, 1.25 lb. emery flour, 3 qt. turpentine, 2 qt. turpentine substitute, 1 pt. methylated spirit, and either 1.25 lb. pumice powder or 0.5 oz. jeweler's rouge.

Oxygen from air. L. BERGFELD and A. WEYRICH. Aust., 70,942, Jan. 10, 1916. In obtaining O from air, N_2O_5 is oxidized with air, in the presence of steam, to HNO_3 from which, by passage through H_2SO_4 , with heating, O is liberated, while the residual $\text{NO}_2 \cdot \text{SO}_3\text{H}$ is decomposed, by the action of steam, into H_2SO_4 and N_2O_5 which is treated as specified. Cf. C. A. 9, 237.

Non-explosive preparations. FARBW. v. M. L. & B. Aust., 70,653, Dec. 10, 1915. Sulfite cellulose end lyes, or their essential constituents, or phenols or their salts, are incorporated with the nitro- or di- and poly-nitro compds., especially the di- and trinitro-phenol salts.

Preparation of lithographic metal plate surfaces. F. NIEMEYER. Ger., 286,367, Feb. 9, 1913. The plates are treated with a dil. acid holding in suspension a finely divided material which is not attacked by the acid and which settles slowly, so that it gradually weakens the action of the acid on the plate, and finally stops it altogether. If desired, the process can be repeated by stirring the liquid. Especially suitable for the treatment of Zn plates are mixts. of the salts of 2 metals, such as the salts of Fe and Cu, especially CN compds. of these metals. These are not attacked by the acid of the bath, and, on account of the fineness of the particles and low sp. gr., they remain suspended for some time in the liquid.

19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

The production of silica (quartz) in 1914. FRANK J. KATZ. U. S. Geol. Survey, *Mineral Resources of U. S.*, 1914, Pt. II, 443-8 (separate, published Oct. 14, 1915).

E. J. C.

Influence of the Al_2O_3 - SiO_2 ratio on the properties of porcelain glazes. R. RIECK AND W. STIEGER. *Sprechsaal* 48, 390-2(1915).—Glazes with 0.3 K_2O , 0.7 CaO , 0.3-2.0 Al_2O_3 , 6-16 SiO_2 were burned on porcelain at cone 15. With more than 9-10 SiO_2 an enamel-like turbidity was obtained, changing to complete opacity with higher SiO_2 . Crazing appeared below 6-8 SiO_2 and with 0.3-0.4 Al_2O_3 . The coeff. of expansion varied from 294×10^{-8} to 532×10^{-8} and was independent of the Al_2O_3 : SiO_2 ratio with increasing percentage of fluxes. The alkalis principally seem to increase the coeff. Glazes having a coeff. less than 400^{-8} were free from crazing, this being close to the coeff. of the body (50% Zettlitz kaolin, 25% quartz, 25% feldspar). R. K. H.

The adsorptive power of clays, kaolins and talcs. P. ROHLAND. *Apoth. Ztg.* 31, 40-2(1916); cf. *C. A.* 9, 2322.—Just as it has been found that animal charcoal adsorbs colors of animal, plant and artificial origin, such action being most pronounced in the case of blue and violet dyes, less so with red and green, and least of all the yellow and brown, in the present paper it is shown that the rate or order of adsorptive activity is given in the following scale: (1) methylene blue, (2) methyl violet, (3) malachite green, (4) brilliant green, (5) bordeaux red, (6) eosin, (7) vesuvin, (8) aniline yellow.

W. O. E.

Light porous bricks. ANON. *Brit. Clayworker* 24; *The Brickbuilder* 1916, 47.—Porosity may be secured by (1) adding sawdust, naphthalene, flour or paper pulp which burn out (coal causes overfiring); (2) using clay as a binder for kieselguhr, asbestos, silicate cotton, etc.; a typical mixt. is 7 lbs. kieselguhr, 3 lbs. asbestos, 5 lbs. clay mixed with water and burned to 1000° . Absorption should be 100%.

C. H. KERR.

Bricks for high temperatures. W. A. HEISEL. *Brit. Clayworker* 24, 183(1916).—A general description.

C. H. KERR.

Notes on the occurrence and use of flint clay. J. H. HANCE. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 639-48.—Typical analyses are given and the uses, geological occurrence, methods of sampling and testing and methods of development of deposits are described. A bibliography of the occurrences of flint clay is included.

E. J. C.

Statistics of the pottery industry in the United States in 1914. JEFFERSON MIDDLETON. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II (preliminary issue dated Aug. 6, 1915).

E. J. C.

Statistics of the clay-working industries in the United States in 1914. JEFFERSON MIDDLETON. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 455-548 (separate, published Oct. 23, 1915).

E. J. C.

Rough surfaced ceramic plates. UTZSCHNEIDER & E. JAUNEZ. *Aust.*, 70,826. Dec. 27, 1915. Granules of carborundum are incorporated in the upper layer of a burned plate. Cf. *C. A.* 9, 1984.

Securing metal coatings to ceramic surfaces. L. HELLER. *Ger.*, 286,537, Oct. 12, 1913. See U. S., 1,126,211 (*C. A.* 9, 701).

20. CEMENT AND OTHER BUILDING MATERIALS.

C. N. WILEY.

The cement industry in the United States in 1914. ERNEST F. BURCHARD. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 221-59 (separate, published Aug. 23, 1915).—Statistics.

E. J. C.

The production of lime in 1914. G. F. LOUGHLIN. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 363-73 (separate, published Oct. 14, 1915).

E. J. C.

Tests of Douglas-fir bridge stringers (to determine the effect of treatment on strength). H. B. MACFARLAND. Eng. of Tests, A. T. and S. F. Ry. System, Am. Ry. Eng. Assoc., *Bull.* 184 (1916) (to appear later *Proc. Am. Ry. Assoc.* 17, Pt. II).—Over 50 7 in. $\times$ 16 in. $\times$ 15 ft. D. fir bridge stringers were creosoted by the boiling under vacuum process and tested for strength in comparison with a similar number untreated. The results indicate that about $\frac{1}{3}$ of the moisture in the wood was removed by the treatment; the treated material lost about $\frac{1}{4}$ of its original av. strength; its stiffness was not affected; the loss in strength was not confined to the area penetrated by the creosote. Detailed records and photographs are given.

GEO. M. HUNT.

Methods for the examination of bituminous road materials. P. HUBBARD AND C. S. RÆGEV. U. S. Dept. Agr., *Bull.* 314, 48 pp. (1915).—A revision of a previous bulletin (cf. C. A. 6, 540). A detailed description of methods (with numerous cuts of app., report forms, tables, and an outline of equipment for a lab.), under the following captions: classification of materials, scheme of examn., sp. gr. detn., sp. viscosity detn., float test, penetration test, m. p., flash and burning points, volatilization test, distn. test, dimethyl sulfate test, bitumen sol. in CS_2 , bitumen insol. in paraffin naphtha, bitumen insol. in CCl_4 , fixed C, paraffin scale, extn. of bituminous aggregates, grading the mineral aggregate, voids in the mineral aggregate, bituminous emulsions.

F. W. SMITH.

Cements. L. P. BASSER. Brit., 22,644, Nov. 17, 1914. Modifications in the process of 17,873, 1913 (C. A. 9, 365), for mfg. cement or hydraulic lime from CaSO_4 , clay, and charcoal, consisting (1) in employing a furnace having two zones of different oxidizing powers, (2) in first treating the CaSO_4 with C under the conditions described in the parent specification, and subsequently mixing the lime obtained with clay, (3) in using an excess of clay so as to obtain a slag, and then either roasting the slag in presence of lime or CaCO_3 , or granulating the slag and mixing it with slaked lime to form slag cement. Both zones may be oxidizing, or the first zone may be reducing or neutral according to the proportion of C in the charge, and in the extreme case no C is present in the charge.

Rough stone. C. SCHNEIDER. Aust., 70,827, Dec. 27, 1915. In the manuf. of castings of cement and finely divided combustible matter, the latter is incorporated only in the outer layer of the block.

Artificial stone. A. RINNE. Brit., 28,417, Dec. 9, 1913. Artificial stone or synthetic marble slabs and the like composed of or containing $\text{Ca}(\text{OH})_2$ or $\text{Mg}(\text{OH})_2$, or other alk.-earth mixed with mineral filling materials or coloring matter are cast or pressed sep. in molds of the same size as the required slab, and are then suspended vertically while being hardened by CO_2 treatment so as to prevent distortion. The suspending means, such as metal wires, threads, or grips are pressed or embedded in the slabs during the casting or pressing operation. The slabs thus produced may be smoothed by means of powders and polished in the usual way, but preferably, polished steel molds are used, the smoothing operation being thereby rendered unnecessary.

Artificial marble. H. BRUSCH. Aust., 70,872, Jan. 10, 1916. The major portion of the H_2O is removed from the mass which has been made plastic with a little H_2O , by compression in two stages, whereupon the mass is broken up into pieces and, after this mass has been rolled out upon a perforated board covered with muslin, the coloring

matter is applied and a second rolled layer is superimposed, the whole is rolled together, compressed axially, and again rolled out.

Artificial stone slabs. A. HARTMANN. Aust., 70,937, Jan. 10, 1916. Artificial stone slabs are manufd. by working together a mixt. of hydraulic binder, well dild. with H_2O , and mineral fiber, on the pulp machine. Asbestos and slag wool are employed together.

Impregnating wood. GRUBENHOLZIMPRÄGNIERUNG GES. M. B. H. Aust., 70,654, Dec. 10, 1915. In the impregnation of wood with aq. solns. of dinitrophenols or their salts, with or without the addition of other substances, such as inorg. salts, adding to the solns. alkali chromates, dichromates, iodates, chlorates, borax, or dialkali phosphates, alone or in admixt.

Impregnating and preserving wood. M. MAYERL, JR. Aust., 70,732, Dec. 27, 1915. The wood is coated with an easily absorbed liquid such as tar oil, or the like, mixed with a readily combustible compd. such as alc., benzine, or the like, in such proportion that, upon burning this admixt. neither the other constituent of the mixt. nor the wood is kindled or destroyed, so that upon kindling, the readily combustible constituent burns and serves to burn the satg. agent into the wood. In a modification of the process, melted pitch, rendered odorless and difficultly fusible by removal of the volatile constituents, and preferably in admixt. with colophonium or the like, is burned onto the previously heated or artificially dried wood as a glaze.

Preserving and restoring wood. S. ENDRÖDI. Aust., 70,652, Dec. 10, 1915. The well dried article is imbedded in a paraffin-wax mixt., solid at the ordinary temp. m. below 100° , and contracting considerably upon solidifying. The wood is first heated to the m. p. of the molten mass, wherein it is heated, and the whole is allowed to cool, then the paraffin-wax casing is removed and the surface of the wood cleaned by means of a suitable solvent.

Destroying wood worms. J. M. LAP. Brit., 100,019, Jan. 14, 1916. Wood worms and other vermin in wood, etc., are destroyed by the application of a compn. consisting of Hg ointment, NaCl and wax. Coloring matter, such as yellow ochre and aniline dyes, may be added. The compn. destroys the parasites and fills up the holes.

21. FUELS, GAS, TAR AND COKE.

J. D. PENNOCK.

A test of a surface-combustion furnace. E. SCHRAMM AND J. R. CAIN. *J. Ind. Eng. Chem.* 8, 361-5(1916).—A laboratory surface-combustion type of gas furnace was tested by making simultaneous measurements of air and gas consumed, of flue gas compns. and of temps. developed with various rates of combustion. The effect on temps. of varying air-gas ratios was also studied. The highest temp. reached was 1675° , at which point the alundum muffle failed. The test established that complete combustion could be attained without excess air, that the best air-gas ratio was 5:3, and that a 20% excess of air caused a lowering of the furnace temp. of 100° .

E. SCHRAMM.

Fuel briquetting in 1914. EDWARD W. PARKER. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 57-60.—The production in 1914 was 250,000 short tons valued at \$1,500,000. Raw materials and binders are discussed. "The chief objection to the use of pitch binders is the emission of smoke when first fired, which

results in the deposition in the flues and on other surfaces of a tarry soot, which is difficult to remove."

E. J. C.

The production of coal in 1914. C. E. LEAHER. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 587-746 (separate, published Nov. 29, 1915).

E. J. C.

The production of peat in 1914. CHAS. A. DAVIS. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 375-85 (separate, published Oct. 9, 1915).

E. J. C.

Peat as a source of power. GEORGE FLETCHER. Some chemical aspects of the peat problem. GILBERT T. MORGAN. *J. Dept. Agric. Tech. Instruction Ireland* 16, 33-45(1916); *Nature* 97, 19-23(1916).—It is considered that the industrial utilization of peat can be most efficiently brought about by gasifying it in gas producers, as this procedure renders feasible the recovery of several valuable by-products. The combined nitrogen of the peat can be economically recovered in the form of $(\text{NH}_4)_2\text{SO}_4$. This valuable fertilizer together with the peat ash containing potash and phosphoric acid can be restored to the land from which the peat had been taken. Peat tar, another by-product, can be fractionated into the following useful materials: refined pitch and tar, candle wax, lubricating and burning oils, and very powerful disinfectants. The aq. distillate from the producer contains MeOH, acetone, pyridine bases and crude AcOH, all of which are capable of recovery and utilization.

W. H. ROSS.

Coal-gas residuals and their application. FRED. H. WAGNER. Johns Hopkins Univ. *J. Franklin Inst.* 181, 505-24(1916); cf. *C. A.* 9, 142.—A comprehensive description of the chem. reactions involved and the procedure used in the recovery of graphite, tar, S, NH_3 and CN compds. in the destructive distn. of coal. An outline is given of the fractionation of the tar, and the manuf. of dyes, explosives, pharmaceuticals, and chemicals from the various fractions.

JOSEPH S. HEPBURN.

Coal problem. H. E. ARMSTRONG. *J. Soc. Chem. Ind.* 35, 220-71(1916); *J. Gas Lighting* 133, 416(1916).—An economic discussion on the utilization of coal.

R. H. SAWENS.

Coal handling and carbonization. J. DICKSON. *J. Gas Lighting* 133, 417-8 (1916).—A description of economics in coal handling as practiced at the Kirkintilloch Gas Works is given. In reference to carbonization, D. advocates greater production of gas of lower value, showing that it serves as well for most purposes. By giving careful attention to heats and settings an av. yield of 12,000 cu. ft. of 15.5 c. p. gas per ton is attained. The resulting coke is hard and gives very little breeze. A considerable advantage of this process is the automatic removal of C from the retorts. When the cake becomes about $\frac{1}{4}$ in. thick it falls off; this is attributed to the rapid retort charging followed by an increased pull on the exhaustor.

R. H. SAWENS.

Carbonization of coal in gas works. J. W. NAPIER. *J. Gas Lighting* 133, 407 (1916).—N. points out the advantage of vertical retorts over the horizontal type. There is no complicated machinery for charging and discharging; the capacity is greater; operation is more simple; coke of high quality is produced. A disadvantage at present is the lower yield of C_2H_4 and C_2H_2 . Expts. to increase the NH_3 yield were tried, the most successful being the passage of steam intermittently through the red-hot coke. In this way a slight increase of NH_3 was produced and a considerable increase in the volume of gas due to the H_2O gas formed.

R. H. SAWENS.

Carbonization and purification. J. DICKSON AND W. BENNET. *Gas World* 64, 200-3(1916).—The papers are confined to the personal experience of D. and B. and contain many useful details of coal handling, carbonization and gas purification in practical day operation.

M. L. TROWBRIDGE.

Purification (of gas). W. BENNET. *J. Gas Lighting* 133, 419-22(1916); *Am. Gas Light J.* 104, 202-5(1916).—Light tars and tar fog must be completely removed before the gas enters the scrubbers in order to avoid "clogging up" in the scrubbers and oxide purifiers. The small amounts of CO_2 escaping the scrubbers, and CS_2 produced in modern gas practice are of little consequence, the main problem being the removal of the NH_3 and H_2S . Since the NH_3 pressure of the soln. must be less than that of the gas in order to have any absorbing value, it is wrong to place a washer on the exhaust side. NH_3 absorption increases with decrease of temp. but this must not be carried low enough to throw out C_2H_4 and C_4H_4 . Dry purification with Fe_2O_3 seems to be most practical for removal of H_2S and, under certain conditions HCN and CS_2 . The fouled material is easily revived by passing air through it. In a series of oxidation boxes it has been found possible to introduce air in such a way that the oxidation goes on at the same time as the sulfiding. The reactions do not take place extensively side by side however. The soln. of the problem is to use the boxes in either forward or backward rotation, the valves working either way. A number of factors influence the efficient working of oxide purifiers: the physical state of the oxide, its size, moisture and compn. As a mixing material old oxide is preferable to sawdust or coke breeze. In the purifier the chemical action evolves heat which should be conserved to render the oxide more efficient. If the oxide is too moist this heat is taken up in evapg. the H_2O . Better results are obtained by artificially heating the boxes by means of interior steam coils. Light oils and tar fog together with moisture and heat are largely responsible for caking of the oxide. Acidity of the oxide should be avoided because of the formation of FeS_2 which is not easily revived. To correct this condition a trace of NH_3 is allowed to go forward with the gas although enough usually passes the scrubber to keep the purifiers alk. A downward flow of gas through the purifiers is desirable. In explanation of the fact that S is occasionally found deposited in the service pipes when the gas leaving the works rarely shows a trace, attention is called to the reversible reaction which takes place with moderate speed at temp. above 77° , $\text{CS}_2 + \text{H}_2\text{O} \rightleftharpoons \text{CO}_2 + 2\text{H}_2\text{S}$.
R. H. SAWENS.

Judging the accuracy of generator-gas analyses. F. HOFFMANN. *Z. anorg. Chem.* 29, I, 46, 54-6(1916).—From a study of the volumetric compn. of gas mixts. resulting from the dry or wet gasification of C with the aid of air, H. has devised a scheme for detg. the accuracy of a number of given generator-gas analyses. By means of formulas given in the text the gas is divided into 2 portions, the "de-gasification" (Entgasung and the "gasification" (Vergasung); the latter, considered independently, is studied by further formulas, or more simply by an accompanying diagram, as to whether and in what amts. its percentage compn. deviates from the volumetric compn. as previously detd. by analysis. The degree of deviation enables one to judge as to whether the analysis may be considered as correct, doubtful, or false. The method is explained by numerous examples. A large number of the generator-gas analyses reported in the literature are inaccurate according to H.'s formulas.
F. W. SMITH.

The production of natural gas in 1914. JOHN D. NORTROP. U. S. Geol. Survey. *Mineral Resources of U. S., 1914*, Pt. II, 747-818 (separate 32, published Dec. 15, 1915).
E. J. C.

Pitch for gas making. A. YUILL. *J. Gas Lighting* 133, 422(1916); *Gas World* 64, 174(1916).—10% of a hard pitch fusing at 90° , broken into small pieces and thoroughly mixed with a good coking coal and carbonized in a vertical oven will give satisfactory results and will yield as found by expts. 9488 cu. ft. of gas per ton of pitch. Compared with all coal results the admixt. of coal and pitch yielded rather less coke per ton of material; rather more tar and about the same quantity of liquor; and 262 cu. ft. less

of gas of higher calorific value. The mixed coke is of excellent appearance and burns well. In a horizontal retort a 5% mixt. gave satisfactory results. M. L. T.

Increasing the yield of hydrocarbons in gas and tar. A. ROLLASON. *Gas World* 64, No. 1646, *Coking and By-Product Section*, 10(1916).—A series of tests has been made on low grade coking slacks with and without the addition of limestone before carbonization. Careful measurements of the volume and calorific value of gas were made. The results obtained per ton of coal carbonized follow. The ash content of the coal was 26.9%.

The manufacture of coke in 1914. C. E. LESHER. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 387-442 (separate, published Oct. 13, 1915).—Statistics. E. J. C.

Portable gas detector (BURRELL) I.

Gaseous-fuel furnaces. J. M. RUSBY. *Brit.*, 22,425, Nov. 12, 1914. The temp. of combustion in a retort furnace heated by a combined gas producer is controlled in two stages, namely (1) by supplying steam to the producer in sufficient quantity to maintain the temp. of the fuel bed at a point below that dangerous to the refractory material of the producer, or at which clinker is formed, and (2) by admitting inert gases, e. g., returned combustion products, to the chamber in which the producer gas is burned with air.

Nitrogen compounds and combustible gas from nitrogenous fuel. C. F. MAULE. *Aust.*, 70,612, Dec. 10, 1915. The necessary lowering of the generator temp. is effected by the return of a portion of the cooled gas from the generator. This gas is allowed to generate and take up the greatest possible amt. of steam, whereby, in addition to the cooling effect, a marked decrease in its combustibility results. A modification consists in employing a very moist fuel (peat with about 60% H₂O) in the generator.

Recovering ammonium sulfate from distillation gases. BERLIN-ANHALTISCHE MASCHINENBAU-AKT.-GES. *Aust.*, 70,650, Dec. 10, 1915. The condensate falling beyond the saturator, at the high temp., is treated with an excess of H₂SO₄, and this mixt. is returned to the saturator.

22. PETROLEUM, ASPHALT AND WOOD PRODUCTS.

F. M. ROGERS.

Petroleum in 1914. JOHN D. NORTROP. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 893-1098 (separate 33, published Jan. 12, 1916).—Statistics. E. J. C.

United States standard tables for petroleum oils. S. W. STRATTON. *Bur. Standards, Circular 57*, 64 pp.(1916).—This circular contains the following tables:

No. 1. Sp. gr. at 60°/60° F. of oils having, at the designated temps., the apparent specific gravities indicated. No. 2. Degrees Baumé at 60° F. of oils having, at the designated temps., the apparent degrees Baumé indicated. No. 3. Vol. that would be occupied at 60° F. by a quantity of oil, of various sp. grs., occupying unit volume at the designated temps. No. 4. Degrees Baumé, lb. per gal., and gal. per lb. corresponding to the designated sp. grs. No. 5. Sp. grs., lb. per gal., and gal. per lb. corresponding to the designated degrees Baumé. These tables apply to all crude and refined petroleum oils produced in the United States. F. M. ROGERS.

The effect of temperature on the formation of olefins from petroleum at atmospheric pressure. G. EGLOFF AND T. J. TWOMEY. *Mel. Chem. Eng.* 14, 247-50(1916); cf. C. A. 10, 820.—The object of the authors was to show the influence of temp. on the unsatd. hydrocarbon formation in the fractions boiling up to 95°, from 95 to 120°, 120 to 150°, 170 to 230°, 230 to 270°, and 270° to tar, and in the gasoline cut up to 150°. A gas oil derived from Penn. crude petroleum was cracked in the gaseous state by passing it through a steel tube at atm. pressure at the following temps.: 450°, 500°, 550°, 600°, 650°, 700°, 750° and 800°. The recovered oil from each expt. was distd. with the aid of an efficient fractionating column. The % unsatd. compds. in the different cuts was detd. by means of 95% H₂SO₄. Ten cc. of oil were measured into a Babcock milk bottle, the neck of which was calibrated in tenths of a cc.; one cc. of 95% H₂SO₄ was then added. The bottle was shaken for 5 mins. with cooling. Following the same procedure 2, 3 and 4 cc. of acid were added, making 10 cc. in all. The bottle was centrifuged for 3 mins., enough H₂SO₄ put in to bring the unabsorbed oil upon the scale in the neck of the bottle, and the latter again centrifuged until no further increase of unabsorbed oil was obtained. The amt. of unabsorbed oil was read, and the unsatd. formation was found by difference. The oil used for the cracking expts. was not affected by the 95% acid; it boiled between 250 and 350°. The fraction of recovered oil cracked at 450°, boiling from 0 to 95°, contained 36% of unsatd. compds. At 500° this same fraction contained 40% of unsatd. compds.; at 550°, 51%; at 600°, 50%; at 650°, 39%; at 700°, 29%; at 750°, 19%; and at 800°, 5%. For the fraction 95° to 120°, the max. of unsatd. compds. is 39% at 550°, and the min. 4% at 800°. The max. amt. of unsatd. hydrocarbons in the 120° to 150° fraction is 35% at 550°, and 10% at 750°. The 170 to 230° cut has its max. of 20% at 700°, and min. 11% at 550°. The 230 to 270° fraction has a max. of 16% at 700°, and a min. of 1% at 450°. The 270° to tar fraction has a max. of 20% at 700° and 1% at 450°. The % of unsatd. compds. in the gasoline cut, from 0 to 150°, was 44% at 550°, and 5% at 800°. In the cracked oil, the total unsatd. formation increased with temp. with indications that a decrease would have been found at the higher temps. The change in compn. of the lower boiling fractions of the cracked oils with increase of temp. may be represented by low boiling paraffins to low boiling olefins to low boiling aromatics. In the higher boiling fractions, the change may be expressed as follows: high boiling paraffins to high boiling olefins to high boiling aromatics. O. E. BRANSKY

Experiments on the production of gasoline from hydrocarbon oils of high boiling points. E. L. DAVIES. *J. Ind. Eng. Chem.* 8, 114-8(1916).—The purpose of the author was to det. the best conditions for cracking the oil, and for satg. with H those portions converted into unsatd. compds. The app. consisted of a superheater for steam a retort for distg. the oil under pressure, a chamber for cracking the distd. oil in the presence of H made by passing steam over red hot iron and steel shavings, a condenser and a meter for measuring the gases. The oil was distd. from the retort at pressure varying from 60 to 100 lbs. The oil vapors were mixed with the superheated steam. the mixt. passing on through the cracking and hydrogenating chamber, which was kept at 650 to 675°. The rate of flow of the steam was about 10 lbs. per gal. of oil.

The steam and cracked-oil vapors were condensed, and the oil condensate sep'd. from the water. The best yield of naphtha (38%) was obtained by distg. the oil at the rate of 17 mins. per gal., with the steam temp. 625° and the temp. in the cracking chamber 650° . The cracked products reacted readily with the nascent H. The yield increased with pressure. The residue left after distg. off the naphtha can be re-cracked satisfactorily. Oils having higher boiling points are cracked more easily than those with lower boiling points, but the production of gas is greater. O. E. BRANSKY.

Naphthenic acids in Balachanski petroleum residues. J. HUTT. *Chem. Tech. Ztg.* 33, 43(1915).—The oil distillates are treated with NaOH which removes the acids in the form of Na soap. These soaps are then salted out with NaCl, and heated to remove H_2O . The dried soaps are distd. with steam to remove free oil. The residue in the steam still is then decompd. with mineral acids. The naphthenic acids so obtained from spindle oil possess a sp. gr. of 0.9506 at 20° , and an acid value of 171.8, and boil between 160° and 180° at 2.5 mm. pressure; those obtained from machine oil have a sp. gr. of 0.9461 at 20° , an acid value of 169.2, and boil between 160 and 300° at 2.5 mm. pressure. O. E. BRANSKY.

Area, distribution, and present production of the petroleum deposits of Argentina. E. M. HERMITTE. *J. Ind. Eng. Chem.* 8, 194(1916).—In 1914, 44,000 cu. meters of crude oil were produced; up to Aug., 1915, 48,500 cu. meters were obtained from 10 wells. The deposits are found principally in Cachenta, Mendoza, Comodoro Rivadavia, and in the provinces of Salta and Jujuy. The oil has a high sp. gr., and only a small amt. of S. O. E. BRANSKY.

The production of asphalt, related bitumens, and bituminous rock in 1914. JOHN D. NORTHROP. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. II, 347-62 (separate, published Oct. 18, 1915). E. J. C.

Identification of bituminous materials. H. B. PULLAR. *Oildom* 6, 130-2(1916). —A review. F. W. SMITHER.

Temperature control in wood distillation plants. R. B. GOETSCHUS. *J. Ind. Eng. Chem.* 8, 196(1916).—Temp. control of the retorts is possible only where the raw material is uniform in size. When the size of the blocks varies, the smaller pieces give up their free water and are decompd. before the larger pieces have become water free. Pyrometric regulation of the destructive distn. of wood will materially increase the yield of its important products, but uniformity of the raw material is a necessary preliminary to proper temp. control. O. E. BRANSKY.

Temperature control in wood distillation. R. C. PALMER. *J. Ind. Eng. Chem.* 8, 283-4(1916); cf. *C. A.* 9, 2587.—P. contends, contrary to the views of Goetschius (preceding abstract), that pyrometric regulation of wood distn. retorts is of advantage, even when the size of the blocks of wood shows considerable variation. Equal mixts. of large pieces of split wood and smaller pieces of sawed wood more readily gave the desired rate of rise of temp. than either of the two kinds alone. By proper control of temp., the variability of size of the blocks may even prove an advantage. O. E. B.

Potash from fir mill waste. H. F. ZOLLER. *J. Ind. Eng. Chem.* 8, 105-8(1916). —One lb. portions of ashes obtained from large mill waste incinerators for burning butts, slabs, and sawdust of Douglas fir, were digested with 1 liter of H_2O at 80° to 90° for 24 hrs. The insol. matter was filtered from the ext., and the residue washed until the filtrate measured 1 liter. The ext. was analyzed for K by the perchlorate method. Amts. varying from 15.65 to 21.3 lbs. of K_2O per ton of ash were obtained from Douglas fir ash. From cedar ash 5.99 lbs. per ton of ash were obtained. The ashes consisted largely of charcoal, and inorganic matter from occluded soils. A large amt. of NaCl

was found in several samples, and this is explained by the fact that the logs in their transportation by water to the mills became impregnated with salt sea water.

O. E. BRANSKY.

Examination of bituminous road materials (HUBBARD) 20.

Purifying oils. E. V. EVANS and SOUTH METROPOLITAN GAS CO. Brit., 22,147, Nov. 6, 1914. S is eliminated from an oil by heating the oil, either in the liquid or vaporous condition, with H, or with a gas containing free H, in the presence of a catalytic agent or contact substance; the H_2S which is produced is removed by absorption in reagents. Ni, Fe, Co and Cu, deposited in porous nuclei, are cited as catalytic agents; and pumice, fire-clay, and asbestos are mentioned as suitable contact substances. Coal gas is cited as an alternative to H. The catalytic material used in the purification of coal-tar naphtha may be prepared by steeping porous fire-clay spheres in a satd. soln. of $NiCl_2$, and reducing the salt in a stream of H or coal gas at a temp. of 300-350°. It is stated that hydrogenation of the oil does not take place.

Cracking oils. A. M. MCAFEE. Brit., 22,244, Nov. 9, 1914. The high boiling constituents of mineral oils are converted into low boiling hydrocarbons by heating the oil in the presence of finely divided Al, Zn, Fe, or other metal capable of reacting with Cl or HCl, and simultaneously passing a current of Cl or HCl gas into the oil. An aluminous material, such as Al_2O_3 obtained by drying $Al(OH)_3$, may be used in place of Al. The Al may be used in the form of "aluminium bronze" powder, com. Al containing Zn, pure Al ground with coke, etc., or Al amalgam. The vapors of the lighter hydrocarbon escaping from the still may be cooled to 300-350° F., in order to condense and return to the still the heavier constituents of the vapors. The oil under treatment is fed continuously to the still, the catalytic activity of a charge of Al being spread over 2-3 days. The still is fitted with an agitator. A granular coky mass containing the aluminous matter is formed, and may be removed from time to time and replaced by additional quantities of Al. In treating oils containing S, the S is disengaged in the form of H_2S ; where the S content is high, a preliminary purification of the oil is resorted to.

Cracking oils. A. M. MCAFEE. Brit., 22,243, Nov. 9, 1914. High boiling mineral oils are converted into gasoline and other low boiling hydrocarbons by boiling them with $AlCl_3$, cooling the vapors to a temp. of 350° F. or less, and returning the condensed portion to the still for further treatment. About 5% of $AlCl_3$ is employed, and fresh oil is added from time to time to render the vol. of oil constant. After 2 or 3 days the $AlCl_3$ accumulates in coky granules and begins to lose its activity. The period of activity may be lengthened by passing Cl into the still. If the vapors are cooled to 300° F., gasoline constitutes the major portion of the product escaping to the condenser. When S-bearing oils are treated, the S is disengaged as H_2S ; but when the S content is high, it is preferable to adopt a preliminary treatment with H_2SO_4 . The $AlCl_3$ may be recovered in the manner described in 22,923, 1914.

Motor fuel. G. E. HEYL and T. T. BAKER. Brit., 21,738, Oct. 29, 1914. A fuel for internal combustion engines consists of 75-50% of petrol, paraffin, or other mineral-oil fuel, mixed with 25-50% of the liquid obtained when the 170-230° distillate (middle oil) of coal tar or analogous tars is freed from naphthalene and tar acids. The mixt. is filtered from a deposit, probably of bases, before use.

Motor fuel. P. SUCHY. Brit., 22,191, Nov. 7, 1914. A fuel for internal-combustion engines is obtained by dissolving in fuel hydrocarbons $(HO)_2C_6H_7CO_2H$ or other substances containing the group OH in combination with carboxylic acids or esters,

and distg. with a reflux condenser. In an example, illuminating oil, a light benzine, EtOAc, ether and $(\text{HO})_2\text{C}_6\text{H}_4\text{CO}_2\text{H}$ are distd. together.

Motor spirits. J. J. SHEDLOCK. *Can.*, 166,101, Nov. 16, 1915. Impurities and solid matters are removed from liquid hydrocarbons in the first stage of their treatment by forcing the liquid hydrocarbons through heated solids having an affinity for the impurities and solids of the hydrocarbon.

23. CELLULOSE AND PAPER.

A. D. LITTLE.

Modern development in pulp and paper. W. R. BROWN. *Paper* 18, No. 2, 11-5(1916).—General with regard to paper twines, textiles and specialties. V. N.

Review of the paper textile industry. ANON. *Pulp Paper Mag. Can.* 14, 103-6 (1916). V. NUNEZ.

Origin and development of papermaking in the old world. ALBERT KOMP. *Paper Trade J.* 62, No. 10, 35-8, No. 11, 40-4(1916). V. NUNEZ.

Paper problems at the University of Maine. J. N. STEPHENSON. *Paper* 17, No. 26, 16-8(1916).—The effect on (a) bursting strength, (b) tensile strength, (c) stretch and (d) folding endurance, of concn. and temp. of stock in beater, pressure on wet sheets, and temp. of drying, gave the following general results: Increased concn. of stock increased *a* and *c*, decreased *d*, and had no effect on *b*. Increased temp. of beating gave decrease in all respects. Increased pressure on wet sheets increased *a*, *b* and *d* and decreased *c*. Increasing drying temp. decreased *a*, *c* and *d* and had no effect on *b*. V. NUNEZ.

Wood pulp for paper making. C. F. CROSS. *Nature* 97, 35-7(1916).—Statistics on the production of wood pulp in Canada and other countries, and on the quantity imported annually into Great Britain. W. H. ROSS.

Manufacture of pulp and paper from straw. JAS. BEVERIDGE. *Paper* 18, No. 1, 18-9(1916).—A general description. V. NUNEZ.

Bache-Wüg ground-wood process. ANON. *Paper* 17, No. 21, 18(1916).—The wood in blocks is confined in a digester which is partially evacuated, then treated with SO_2 under pressure and finally cooked with water, NaCl soln. or bisulfite liquor. The wood is then ground. The resulting pulp is stated to be suitable for the manuf. of print paper without the addition of sulfite pulp. V. NUNEZ.

The Friedsam ground-wood process. ANON. *Paper* 17, No. 21, 19(1916).—Mineral fillers or pigments are added to the wood pulp while it is being produced on the grindstone. The pulp is thoroughly impregnated with the filler, improved in color and quality and rendered more greasy. Filler retention is very high. V. NUNEZ.

White mechanical pulp by the Enge process. ANON. *Paper* 17, No. 18, 11-5 (1916).—A digest of German and Austrian opinions of the Enge process in which wood is boiled with water for about 6 hrs. at temp. of 230°F . and pressure of 147 to 176 lbs. before grinding. The process is generally considered as of great significance and excellent results have been obtained by its use. In the manuf. of print papers, the use of N. G. (Enge) pulp permits a decreased percentage of sulfite cellulose, but the opinion is expressed that the saving so effected will be practically wiped out by the increased cost of N. G. pulp over ordinary white ground wood. A report by E. KIRCHNER is very favorable to the strength and printing functions of paper made from N. G. pulp.

V. NUNEZ.

New Enge wood-grinding process. WILLI SCHACHT. *Wochenbl. Papierfabr.; Paper 17*, No. 21, 17(1916).—While admitting the superior strength of N. G. pulp over ordinary white mechanical pulp and the general excellent qualities of the paper in which it is used, S. points out that the samples of paper reported on by Kirchner (cf. preceding abstract) appear to contain less filler and to be made at slower speeds than ordinary newsprint. Exact data concerning yields of pulp (which will probably be lower than for white mechanical pulp), cost of plant and of process are necessary to draw final conclusions.

V. NUNEZ.

More about Enge mechanical pulp. ANON. *Paper 17*, No. 26, 11-2(1916).—The printing qualities of paper made from N. G. pulp are reaffirmed by Kirchner to be excellent. The reliability of K.'s conclusions is questioned by an anonymous writer.

V. NUNEZ.

Beater rolls and bed-plates of basalt. G. F. LOUGHLIN. *Mineral Resources of U. S., 1914, Paper 17*, No. 22, 11-2(1916).—Requirements for the stone are hardness, toughness and a uniform vesicular structure. The stone now used is of German origin but lavas of this general character are found in the western U. S. and may prove usable. The basalt-lava beating tackle is considered excellent for certain classes of paper.

V. NUNEZ.

Sulfite cooking with forced circulation. EINAR MORTERUD. *Paper 17*, No. 23, 13-5(1916); *Chem. Eng.* 23, 103-6(1916).

V. NUNEZ.

Proposed method for the profitable utilization of waste sulfite liquor. HERMAN V. TARTAR. *J. Ind. Eng. Chem.* 8, 226-8(1916).—A process is described for production of EtOH from waste sulfite liquor in which the essential novelty is the method of freeing the liquor from SO₂. This method is as follows: H₂SO₄ is added in amount to be the reacting equiv. of the total SO₂ in the liquor and the liquor concd. *in vacuo* at not over 85°. This drives off the SO₂. Residual traces are carefully neutralized with lime and the concd. liquor is subjected to fermentation which proceeds favorably by the use of ordinary brewer's yeast. A yield of 1% abs. alc. is considered possible. The residue after distn. appears harmless to fish life.

V. NUNEZ.

Ash tests for percent of filler in paper. JOS. E. PLUMSTAD. *Pulp Paper Mag. Can.; Chem. Eng.* 23, 70-1(1916).—General considerations regarding retention of filler and the relation between bulk and strength.

V. NUNEZ.

Resistance of paper to folding in machine and cross directions. W. HERBERG. *Papier Ztg.* 41, 137(1916).—Tests of 918 papers show that the folding strength is greater in the machine direction in case of $\frac{2}{3}$ of the papers and greater in the cross direction in case of $\frac{1}{3}$. Variation between individual specimens of a given class of normal papers is much greater in case of the folding test than in the tensile or stretch tests.

V. NUNEZ.

The paper industry and substitute materials. U. HAASE. *Kunststoffe* 6, 21-2(1916); continuation of *C. A.* 10, 822.—Various combinations of pasteboard and crepe paper with other materials are discussed.

F. W. SMITH.

The production of celluloid coatings. ANON. *Kunststoffe* 5, 291-2(1915).—Celluloid is applied to articles by laying on thin sheets previously warmed and then pressing, by repeatedly dipping the articles into thin celluloid solns., or by spraying the solns. on the articles. Solvents dissolving both the celluloid and the surface of the article to be coated are used to advantage. Mother of pearl effect is obtained by using transparent celluloid mixed with special fish scales. In spraying, the temp. of the solns. is very important. Transparent celluloid is seldom used for dipping. Lacs are sometimes used for dilg. the celluloid solns.

CHESTER TUSTIG.

Plastic composition from cellulose. W. T. BONNER. U. S., 1,173,336, Feb. 29. Dry cellulose is treated with liquid NH_3 and a very reactive product is obtained which yields a substance resembling viscose on reaction with CS_2 and treatment with H_2O .

Preparing sulfite-cellulose back waters for use as a briquet binder. M. PLARSCH. Ger., 286,210, Aug. 20, 1911. The object of the treatment is to remove lime by the addition of H_2SO_4 in slight excess. When H_2SO_4 is added to the back water with heating, or when the lye is heated with H_2SO_4 before briqueting, H_2O -insol. substances sep. from the lye which no longer have the power to act as binders, wherefore a loss of both lye and acid results. This breaking down of the lye can be prevented if the acid is added in the cold, with cooling of the lye. All organic lye constituents remain in soln., and a needless loading of the briquet with non-binding lye constituents is prevented.

Working reed stalks into long fibers and fiber for paper stock. B. VON ORDODY and B. SCHORRIK & Co. Ger., 285,539, June 14, 1914. After ripening, the fibrous material, cut, slit and dried, is treated in roasting vats at $20-30^\circ$ for about 2-5 weeks, with repeated change of H_2O , and then, after washing and drying, it is placed in a petroleum soap emulsion with added caustic alkali, either in open vessels, in layers and cross layers, or under pressure in closed vessels. The fibrous material is washed and the long and short fibers sep'd. at the same time, and treated further in the usual manner. The treatment is continued, in open vessels, for 2.5-3.5 hrs., at a pressure of 1-1.5 atm. for about 1-1.5 hrs. The resulting spun fiber is strong, soft and lustrous.

Washing stripped vegetable fiber. F. KRUPP, AKT.-GES. Ger., 285,929, May 28, 1914. Addition to 280,545 (C. A. 9, 1998).—The loose fibers are run alternately over partitions and through a H_2O bath, the surface of which is below the upper edge of the resistance.

Apparatus and methods for reducing and washing paper pulp. C. W. SHARTLE. U. S., 1,173,747-8-9-50, Feb. 29.

Safety paper for checks. J. B. WEIS. U. S., 1,172,414, Feb. 22. Paper pulp for safety paper is mixed with FePO_4 0.5, $\text{Mn}_2\text{Fe}(\text{CN})_6$ 2, $\text{Na}_4\text{Fe}(\text{CN})_6$ 0.5 and PhNH_2 -HCl 1%. Acids and Cl produce blue and brown stains, resp., on the paper, if alterations with such reagents are attempted.

Cellulose esters. H. DREYFUS. Brit., 100,009, Apr. 30, 1915. In the acetylation of cellulose, the H_2SO_4 employed as condensing agent is replaced by equiv. quantities of NaHSO_4 , or other bisulfate, containing a small proportion of free acid; the bisulfate is preferably formed in the acetylating mixt. of Ac_2O , glacial HOAc , and H_2SO_4 , by addition of appropriate quantities of Na_2CO_3 or NaOAc , etc. The bisulfates of K or pyridine are also specified as suitable. The products can be converted (C. A. 8, 1010) into other products of various solubilities as specified in 20,877, 1911, 10,852, 1912, 21,376 (C. A. 8, 1010), 1912, and 22,645, 1912. Cf. also 6,463, 1915.

Colored or bronze paper for packing. H. OESER. Ger., 284,656, Mar. 10, 1914. The paper consists of two transparent sheets of paper, united with the color or design between them. The paper is rendered transparent by the use of an agent which serves both to hold the color and bronze powder, and to cement the paper. As binder between color or bronze and paper, or between both paper sheets, adhesives sol. in H_2O or alc. may be used.

Rendering paper transparent and air- and water-tight. H. OESER. Ger., 285,978, May 19, 1914. The paper is first sat'd. with resin and wax melted in oil, with the addition of alc., is then treated with a colloidal soln. of gelatin, agar-agar or the like. In case

the fixing agent is formed with the aid of a size soln., such coating can be hardened by means of HCHO , alum, or the like. To produce a colored transparent paper, a transparent dye (aniline or vegetable dye) is added to the satg. mass or to the fixing agent. The fixing agent can be melted together with the satg. mass. If a glue-like substance, such as gelatin, glue, or agar-agar, is used as fixing agent, this is first softened in H_2O , and then melted, by warming in alc. Single-ply paper can be made into colored or bronze paper by dusting the color or bronze powder on the satd. sheet.

24. EXPLOSIVES AND EXPLOSIONS.

C. R. MUNROE.

Oxyliquite. LUDWIG SIEDER. *Z. ges. Schiess-Sprengstoffw.* 10, 165-6, 179-80 (1915).—As pointed out in 1906 the basis of this explosive is free O while all others have chemically fixed O. To get a practical explosive it is necessary to have large surface for liquid so that mols. of O and oxidizable substances can come into close contact. Kieselguhr and burnt cork are good absorbents; the former is used so as to be partly satd. with petroleum. Charcoal cannot be used because it reacts with the O to form CO. The procedure of Baldus and Kowastch for use of oxyliquite is as follows: A thick paste-board shell, provided with an inner perforated distribution tube and filled with the harmless mixt. of kieselguhr and any oil, asphalt, soot, or paraffin is introduced into the drill hole. In the central tube is placed a thin admission tube made of paper, and above the latter is a wider paper tube to carry off evapn. products. The stemming may be put on without danger. Weighed amts. of liquid air are at hand in small bottles fitted with metal hose with a conical tip which is introduced into the central admission tube protruding from the stemming. When the bottle is inverted the liquid air rises under its own evapn. pressure from the bottle, through the admission tube and into cartridge where it lodges between particles of the charge, ready to combine vigorously with constituents of the cartridge when explosion is started by elec. ignition. S.'s method is to dip the cartridge into liquid air prior to introduction into bore hole. The excess of O can evap. 4-5 min. without impairing the effects of the explosive while drill holes are being prepd. 40 parts petroleum was absorbed in 60 parts kieselguhr and by using well insulated shells the full strength of the explosive was maintained 8-10 min. after removal from liquid O. The chief objection to oxyliquite is the difficulty of transporting it.

W. C. CORG.

Nitrocellulose or nitroglycerin powders. ALBERT BUISSON. *J. U. S. Artillery* 44, 211-4 (1915).—B. discusses the relative advantages and disadvantages of these 2 classes of propellants. While accidents on French vessels have been shown to be due to nitrocellulose powders the explosions on the 2 Japanese ships Mikasa (1905) and Matsushima (1908) are to be attributed to decomp. of cordite (nitroglycerin powder). The powder which Germany uses in the navy has about 25% nitroglycerin which up to now has never been the cause of any accidents, but this country works over its stock of this powder every four years. Tables are given showing the extent of the erosion caused by cordite and other nitroglycerin powders which produce temps. as high as 3000° . The verdict of A. Trévor Dawson, which appears to be accepted, is as follows: The most important considerations in detg. the best compn. of powder to be adopted are, (1) its keeping qualities and safety under normal climatic conditions; (2) its capability of obtaining the highest possible ballistics, and consequently the flattest trajectory; and (3) its regularity in results, so that the ballistics may not be seriously affected by change of temp. or by the wearing away of the gun due to excessive erosion. All these qualities are secured by the use of a properly manufactured nitrocellulose powder,

whereas none of these conditions can be said to be met by any powder containing nitroglycerin.

CHARLES E. MUNROE.

Report of Chief Inspector of Bureau for Safe Transportation of Explosives and other Dangerous Articles. B. W. DUNN. *Bureau of Explosives Report* No. 9, Feb., 1916; cf. *C. A.* 9, 1392.—Although during 1915 explosives and ammunition of all kinds were transported in larger quantities than ever before they gave rise to but 11 accidents in which none was killed, only 6 were injured and but \$127 of property lost. The chief source of disaster was inflammable liquids, which caused 55 deaths, 470 injuries and a loss of \$851,348 in property, while acids and corrosive liquids came second in the injury wrought. The main report contains 13 statistical tables analyzing the data for the year and in the comparison columns giving *modified* data for previous years. This is followed with appendices which bring the report up to 85 pages of fine print matter. The Chemist's report shows examn. of: new explosives all of which passed the tests; fireworks in which those containing NH_4 salts with chlorates were condemned as liable to spontaneous ignitions; railway time signal fuses in which new substances are successfully replacing the acceptable KClO_4 ; fire engine torches disapproved on errors in construction; rubber scrap and buffed rubber found liable to ignite spontaneously; garbage tankage, dried manure, dried alfalfa, lime, charcoal and other substances gave rise to self-occurring fires. Cylinders for chlorine, packings for carboys, and many other articles were examined and are reported on at length. It is interesting to note that excelsior treated with $\text{Al}_2(\text{SO}_4)_3$ is not a satisfactorily fire-proofed material. Another report describes, with illustration, an app. for detg. the vapor pressure of liquefied petroleum gas.

CHARLES E. MUNROE.

Aluminium in war munitions. ANON. *Metal Ind.* 14, 7(1916).—While before the war shrapnel fuses were made of brass, the larger part of them is now being made of Al containing a small percent of Cu. But Al is still more largely used for war purposes as thermite for ignitions or with NH_4NO_3 as a detonating explosive in shells. It is also in use as tips for rifle bullets and in aeroplane constructions.

CHARLES E. MUNROE.

Cause of transmission of detonation in explosives. A. VOIGT. *Z. ges. Schiess-Sprengstoffw.* 10, 180-2(1915).—A theoretical discussion.

W. C. COPE.

Oil-hardening tank explosion. A. D. BYRNE. *Chem. Trade J.* 58, 164(1916).—An explosion occurred May 22nd, 1915, in 1 of 6 tanks employed by Messrs. Ardol, Ltd., Selby, Yorks in converting oil into a solid by means of H. Each tank was fitted with 3 vertical coils of Cu tubing forming an endless circuit through which hot water was passed. Its temp. normally was about 290° and its pressure 2000 lb. per sq. in. The oil in the tank was heated to a temp. of about 260° and the H, at a pressure of 5 lb. per sq. in. was sent from the bottom upward through the tank to the cleansing plant. B. finds the accident to have been due to a leakage from the copper coil producing an undue pressure in the tank.

CHARLES E. MUNROE.

Benzene explosion at gas works. ANON. *Chem. Trade J.* 57, 388(1915).—An explosion occurred at Beckton works of London Gas Light and Coke Co., Oct. 18, 1915, as purified C_6H_6 was being run from the condenser into the 50-gal. drums in which it was to be shipped. Precautions had been taken as to naked lights, matches, smoking, and fire, and no cause of sparks was found. The building was seriously damaged, one man killed and several injured. The cause was not found.

C. E. M.

Inquiry into Manchester chemical works explosion. ANON. *Chem. Trade J.* 57, 343(1915).—An explosion occurred in a factory for the manuf. of dyestuffs. It is

believed to have originated in the grinding mills where straight and blended materials were treated. The investigation failed to indicate any cause. The material appears to have been a black dyestuff.

CHARLES E. MUNROE.

Temporary gas by-pass over decked subway excavations. *Gas Age* 37, 253-8 (1916).—Under the legend "Danger of Gas Pockets in a Decked Excavation" and "Serious Nature of Gas Explosions," the nature of the construction by which to avoid the formation of pockets in which explosive gaseous mixtures may accumulate is described and the seriousness of the results following gas explosion where these precautions have not been taken is illustrated by citations of explosions which have actually occurred and photographs showing the effects are given.

CHARLES E. MUNROE.

Coal-gas residuals and their application (WAGNER) 21. Aluminium dust (CLEVENGER) 9. Portable gas detector (BURRELL) 1.

Explosive charges of fusible explosives. DEUTSCHE SPRENGSTOFF AKT.-GES. Aust., 70,734, Dec. 27, 1915. The liquid explosive is centrifuged, horizontally, thereby securing high density, freedom from bubbles, and adhesion to the shell.

Explosives. SPRENGSTOFF AKT.-GES. CARBONIT. Ger., 286,736, Apr. 2, 1913. Hexanitrodiphenyl is especially suitable for use as an explosive, alone or in combination with other components. It consists of fine bright yellow crystals which do not attack the skin nor color it, and also has completely neutral properties inasmuch as it does not form salts with acids or alkalis. Furthermore, it is very stable and may be stored without deterioration. It is but slightly sensitive to percussion and concussion. It is insol. in H₂O, slightly sol. in alc., acetone, benzene, and toluene. The flashing temp. is above 320°, and the m. p. is about 230°. Its power exceeds that of hexanitrodiphenylamine about 10%, and that of picric acid to a still greater extent. It is employed in grenades, torpedoes, and mines in a compressed state. Cf. C. A. 9, 392.

Charges for blasts, mines, and torpedoes. SPRENGSTOFF AKT.-GES. CARBONIT. Ger., 286,543, Aug. 28, 1912. [1,3,5-(NO₂)₃C₆H₃]₂S is employed, in cryst. or compressed form, and alone or with the addition of other nitrohydrocarbons, C compds., or O carriers. The product is chem. very stable, has a high explosive action, is easily compressible, yields SO₂ on detonation, does not become yellow, and is not poisonous.

25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

The status of the German dyestuff trade in the U. S. A. L. W. SCHMIDT. *Chem. Ind.* 38, 477-9(1915).

F. W. SMITHER.

Production of aniline black with the aid of a diamine. ALFRED EHRENZEIG. *Z. Farben-Ind.* 14, 41-2, 51-2, 59-60, 67-8, 75-6, 81-2, 90-1, 96-7, 104-5(1915); 15, 1-2(1916).—There are several processes which utilize the catalytic effect of a diamine in the oxidation of the aniline. E. distinguishes three different kinds of action, differing with the ratios of the number of moles of aniline to diamine: 12 to 1, 6 to 1, and 3 to 1. Each of these differs radically from the others. In the first, chlorate, diamine and Cu salts are used; in the second, the catalyzers are Cu salts and diamine, no chlorate being added; and in the third only chlorate and diamine are employed, the oxidation being carried directly to aniline black. The first process is suitable for dyeing when the dry-

ing is effected at 90–100° in a calendar (Glattfärben), and causes no weakening of the fabric. The second process gives an aged black and is particularly applicable where no regular equipment is available. The third process is suitable for steamed-black in dyeing and printing. A single drying is required, the black being entirely ungreenable. Both animal and vegetable fibers can be handled satisfactorily. Ger. pat. 267,628 (C. A. 8, 828) covers the first process. The following ingredients are used in making 30 l. of padding soln. for mercerized or 24 l. for unmercerized goods: 12 moles $C_6H_5-NH_2HCl$, 1 mole *p*-phenylenediamine, $\frac{1}{2}$ mole $NaHSO_3$, 1 mole 90% $HCOOH$, 2 moles $NaClO_2$, 1 mole $CuSO_4$, 1 mole 50% lactic acid, $\frac{3}{2}$ mole $C_2H_5(OH)_2$, $\frac{1}{2}$ mole powdered $Al(OH)_3$, and 1 mole 50% $AcOH$. Dynamometric tests show decreases in breaking strength of only about 1%, as compared with 15% by the usual processes. Stock solns. of the sep. ingredients may be made, but no large quantities of the complete bath should be prepd. at any one time. Complete directions for padding, drying, chroming, etc., are included. For the 2nd process, any drying temp. between 30 and 100° may be used, the ageing period being 2–8 days. In the 3rd process, glycolic acid is used instead of lactic acid. Tables of costs are given, as well as a brief description of a fairly permanent lustering produced on moist fabric by calendaring with fluted rolls.

W. F. FARAGHER.

Removal of the natural impurities of cotton cloth by the action of bacteria. B. S. LEVINE. *J. Ind. Eng. Chem.* 8, 298–302(1916); cf. C. A. 9, 1548.—The following summary is given: (1) "Of all the natural impurities of cotton cloth only the N-containing and the ether-sol. substances when insufficiently removed from the cloth previously to the "chemick," cause yellowing of bleached cloth in the steam test or during storage. (2) The N substances of the fibers were broken down by bacteria so that they were completely removed from the cloth. This transformation in the presence of the $Ca(OH)_2$ has probably resulted in some cases in the formation of ether-free NH_3 or N, $CaCO_3$ and H_2O , and in some in the reduction of the N substances to peptones and amino acids which are easily oxidized to nitrites and nitrates. (3) The ether-sol. substances were removed by bacterial treatment more efficiently than is the case in the ordinary bleaching process. (4) The alc.-sol. substances were very little attacked by the bacteria, probably because of the formation of a Ca salt in the presence of the $Ca(OH)_2$ of the media. (5) None of the bacteria experimented with have transformed the starch of the cloth any further than to dextrins. (6) Bacteria may be profitably employed as a substitute for the present method of purifying cloth preliminary to its bleaching." Full details of the expts. are given with the results in 4 tables. Cf. Hebden, C. A. 8, 3632.

L. W. RIGGS.

The determination of the impermeability of cloth. G. A. LEROY. *Ann. fals.* 8, 377–85(1915).—A description of the "impermeabilimeter," very similar to that previously reported (cf. C. A. 9, 2595), followed by cuts and description of another app. suitable for measuring the impermeability of tissues to air. The rarefaction due to the absorption of CO_2 by KOH , from a definite quantity of air- CO_2 mixt., is the basis of the app. which is similar to the "impermeabilimeter." The space below the diaphragm of tissue which is being tested contains CO_2 -free air and 25 cc. of 20% KOH soln., a handful of glass beads being added to increase the absorption surface. The bell-shaped cover of the diaphragm is closed, at the top, with a 2-hole stopper, through one hole of which passes a pipet, and through the other connection is made with a U tube partly filled with Hg. In each side of the U is an elec. contact. To operate, the pipet, which has a stopcock above and below the bulb, is filled with CO_2 , the air in the space both above and below the diaphragm is brought to atm. pressure, and connection is made with the U gage. After the entire app. has come to const. temp. by standing in a thermostat, the lower cock of the pipet is opened, and CO_2 allowed to run down

and mix with the air in the space above the diaphragm. As it passes through the diaphragm and is absorbed by the KOH, the pressure in the app. decreases, and the Hg in one side of the U tube rises, closing the elec. circuit, and ringing a bell or registering on the chromograph. The time interval between the adding of the CO₂ and the making of the elec. contact is taken as the measure of permeability.

H. S. BAILEY.

Military clothing. EUGEN SEEL AND ALBERT SANDER. Stuttgart. *Z. angew. Chem.* 28, I, 457-63(1915).—The fabrics used in making field-gray uniforms have in a great many cases been unsatisfactory in regard to fastness to light and weather during service. Fading often results in change of shade due to differences in fastness of the dyes used. The resulting shades are often dirty blue, yellow or brown. Many complaints have been made also about the poor wearing qualities of the fabrics. The causes of the unsatisfactory serviceability are attributable to the methods employed in manufacture and dyeing of the fabrics, and to the poor quality of wool used owing to the cutting off of imports. Three methods of producing field-gray dyeings are permissible: Indigo bottom, topped with acid chromed dyes, straight vat dyeing (helindon, thiondigo, algol dyes), and mordant dyeing with acid chromed dyes. The dark wool for mixing is dyed by the first method and constitutes 50% or more of the stock. The remainder can be undyed wool, a lightly dyed wool (as, e. g., "Greenish pearl," an indanthrene mordant-dye dyeing) or a wool dyed lightly with Cu or Cr salts. Gray-green produced by alizarin on indigo bottom is generally deficient in light fastness on account of the great difference in light fastness of the separate components. The greater simplicity of vat dyeing is in its favor especially since vat dyes are now available, which can be used like indigo in an NH₂-hyposulfite vat. Cheap chrome dyes are deficient in light fastness. If the lightly dyed wool for mixing is dyed with inorganic salts, the fastness to rubbing and the strength of the fabric are less than with undyed wool, while the fastness to light is superior. S. and S. have worked out a process for identifying the different dyeings which are allowed in the production of field-gray. Complete tables showing the reagents and their reactions are included. W. F. FARAGHER.

Coal-gas residuals and their application (WAGNER) 21. Manchester dyestuffs works explosion 24.

Developing dyes. BAYER & Co. Aust., 70,921, Jan. 10, 1916. The diazo compds. of the dyes obtained by coupling diazo- or diazoazo compds. with 1-amino-2-naphthyl ethers or their derivs., are coupled with derivs. of 2,5-aminonaphthol-7-sulfonic acid or of 2,8-aminonaphthol-6-sulfonic acid which contain diazotizable amino groups in union with the heteronuclear nucleus.

Body dyes. BADISCHE. Aust., 70,642, Dec. 10, 1915. Body dyes consist of compds. of the following general formula, or their nucleus substitution products, and the substrata common in dye lake manuf., such as alumina, blanc fixé, kaolin, heavy spar, etc.

Yellow monoazo dyes. BAYER & Co. Aust., 70,917, Jan. 10, 1916. The amino carboxylic acids obtained from dehydrothiotoluidine, its homologs and substitution products, as also from the corresponding primulin compds., by oxidation, are diazotized and coupled with acetoacetic acid arylides.

Aldehydes of the anthraquinone series. AKT.-GES. FÜR ANILIN-FABRIKATION. Aust., 70,873, Jan. 10, 1916. The corresponding methylantraquinones are oxidized directly with MnO_2 in H_2SO_4 soln. at moderate temps., *i. e.*, below 100° .

Alizarin. CHEM. FABRIK GRIESHEIM-ELEKTRON. Aust., 70,646, Dec. 10, 1915. *meso*-Nitration products of anthracene are heated with alkalies, with or without the addition of oxidizing agents, in the presence or absence of sulfites or lime.

Converting *o*-amino dyes into pseudoazoimines. CHEM. FABRIK GRIESHEIM-ELEKTRON. Aust., 70,641, Dec. 10, 1915. The *o*-aminoazo dyes are heated with catalyzing metals in the presence of solvents.

Dyes. DURAND and HUGUENIN, SOC. ANON (formerly FARBW. v. J. DURAND, H. & Co.). Brit., 22,247, Nov. 9, 1914. Gallocyanins are condensed with aromatic diamines, containing at least one free NH_2 group, by stirring at ordinary temp. with or without using diluents, such as alc. Gallic acid gallocyanins yield products from which CO_2 has or has not been eliminated according to the working conditions. According to examples, the gallocyanins from gallic acid or Me gallate and nitrosodimethylaniline are condensed with *p*-aminodimethylaniline. 21,949, 1906, is referred to.

Dyes; dyeing. FARBW. v. M. L. & B. Brit., 22,148, Nov. 6, 1914. Stable preps. for addition to indigo fermentation vats are obtained by mixing isolated albuminous substances with H_2O -sol. carbohydrates or glycerol; indigo or indigo white may be added to the mixt., also materials containing bacteria, such as cut hay, hay infusion, or liquids undergoing lactic or butyric fermentation. Suitable albuminous substances are concd. ext. of rye-bran, gluten, vegetable casein, casein, albumoses, peptones, etc.; suitable carbohydrates are molasses, invert sugar, glucose, or maltose.

Dyeing. M. BECKE, W. SUIDA and H. SUIDA. Aust., 70,640, Dec. 10, 1915. In a process of dyeing with quinoneanilide- or anilinoquinone-like dyes, on the fiber, ready-formed or forming quinones of the benzene and naphthalene series, and their derivs., are allowed to act, in the dye bath or on the fiber, upon aromatic amines, their sulfo and carboxylic acids, or upon dyes with free amino groups. Cf. C. A. 10, 278.

Dyeing fiber with water-insoluble vat and mordanting dyes. R. WEDEKIND & Co. Aust., 70,849, Jan. 10, 1916. The dye compds. are applied to the fiber and then converted into suitable dyeing form. Neutral, acid, or alk. aq. suspensions are used, without thickening agents, the labile dye compds., on the fiber, being then converted into the stable compds. by vat treatment and oxidation of the resulting leuco compds., or, in the case of mordanting dyes, by subsequent heating under H_2O or in steam.

Dyeing animal fibers. K. HOFMANN. Ger., 286,411, May 8, 1914. Gaseous or dissolved C_2H_2 is allowed to act on the material (wool) pretreated with Cu compds., whereupon the material is after-treated with dil. acid and dil. NH_4OH or warm NH_4Cl . Dark dyeings are obtained which are fast to washing and milling.

Centrifugal pump with heating and cooling means. P. JERUSALEM. Aust., 70,636, Dec. 10, 1915.

Dyeing and bleaching textiles. J. F. POSSELT. Ger., 286,208, Jan. 3, 1913. Means are provided for the periodic automatic interruption of the flow of the vat liquors.

Fast dyeing on textile goods. SOC. ANON. POUR L'IND. CHIM. À BALE. Ger., 286,410, Dec. 11, 1913. Brown, olive, to black shades are obtained. Amino derivs. of car-

bazole, its homologs and derivs., are applied to the fiber, which is thereupon oxidized as usual for amines.

Continuous bucking of textile goods. E. WEICHERT. Ger., 286,429, Aug. 13, 1912. The material is conducted, successively, in a chamber from which air is excluded, through lye and through a steaming chamber disposed above the bath.

Preparing fiber for spinning. C. A. NEUBECKER. Aust., 70,648, Dec. 10, 1915. A machine is specified.

Cleaning textile stuffs. O. RÖHN. Aust., 70,850, Jan. 10, 1916. Tryptic enzymes are added to the washing liquor.

Fireproofing; bleaching. T. J. I. CRAIG and WHIPP BROS. & TOD. Brit., 22,617, Nov. 17, 1914. Unbleached or partly colored unbleached textile fabrics, etc., are first fireproofed by the process described in 16,153, 1914 (C. A. 10, 98), and then bleached. suitable bleaching agents are NaOCl soln. when treating uncolored fabrics or partly colored fabrics dyed with dyes unaffected by hypochlorite, or H₂O₂ soln. when treating partly colored fabrics dyed with dyes affected by hypochlorite; alkali bicarbonate is preferably added to the bleaching solns. used. Examples of the treatment of gray cotton cloth and striped flannelette are given.

Weighting silk. SCHMID, GEB. Brit., 100,033, Jan. 21, 1916. In the weighting of silk by treating it alternately with metal chloride baths and alkali phosphate baths, and subsequently with an alkali silicate bath, baths of ZnCl₂ or of SnCl₄, or of a mixt. of the two, are employed, to which are added silk and silkworm chrysalids in soln., or the product obtained by boiling silk and silkworm chrysalids in H₂O, or the oily H₂O obtained by boiling the remnants of cocoons known as "shave silk," or other silk waste containing silkworm chrysalids.

Degumming silk. SCHMID, GEB. Brit., 100,029, Jan. 22, 1916. In the ungumming of silk or silk waste, as raw material, yarn, or woven fabric, if the material is free from silkworm chrysalids, the soap hitherto used is partially replaced by gallettadini (silk waste containing silkworm chrysalids), or silkworm chrysalids; if the material contains chrysalids or parts of chrysalids, part or the whole of the soap hitherto used is replaced by soda. Cf. 13,952, 1905.

26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

The production of mineral paints in 1914. JAMES M. HILL. U. S. Geol. Survey, *Mineral Resources of U. S.*, 1914, Pt. II, 103-22 (separate, published July 21, 1915).—Natural mineral pigments, pigments made directly from ores and chemically manufd pigments are considered. E. J. C.

Detection of resin in drier. E. W. BOUGHTON. Bureau Standards, *Tech. Paper* No. 66, 9 pp.(1916).—A discussion of the significance of resin in drier is given. Purchasers of oil drier presumably desire material that is free from resin. The proposed method for the detection of resin is as follows: (1) Test for rosin by the Liebermann and Storch method; (2) if no rosin is detected by (1), treat 0.2 g. of the mixture of unsapon. matter, resin acids and fatty acids, separated from the drier, with 5 cc. of 97% EtOH. A turbidity or deposit of insol. matter shows the presence of resin, but rosin, Manila, shellac and very small amts. of Kauri cannot be detected by this step (3) if no rosin is detected by (1) or (2), esterify 1 g. of the mixt. used in (2) by Wolff's method (cf. C. A. 1, 8, 2495) using abs. EtOH and H₂SO₄, and titrate the unesterified

acids. An acid no. (mg. KOH per g. of the mixt. of unsapon. matter and acids taken) of over 10 shows the presence of resin in the sample. By this step resin can be detected when the amt. is at least 6% of the ash-free, non-volatile portion of the drier.

E. W. BOUGHTON.

Determination of oil and resin in varnish. E. W. BOUGHTON. *Bur. Standards, Tech. Paper No. 65*, 32 pp.(1916).—Existing methods were found to give erroneous results with certain types of varnish. The $C_2H_5(OH)_3$ yields of varnishes, detd. after sapon. with aq. KOH soln., when multiplied by 10, gave figs. which were fairly close to the amts. of oil present, except with varnish containing tung oil, in which case the results were low. Extn. of oxidized films with $CHCl_3$ removed only a portion of the resinous matter present, except with a sample the non-volatile portion of which was mainly rosin. Treatment of varnish with petr. ether did not quant. ppt. the "gum," and the amt. of oil pptd. by this treatment varied with the nature of the varnish. Treatment of the unsaponifiable matter, resin acids and fatty acids (sepd. from varnish) with petr. ether did not quant. ppt. the "gum;" the amt. of fatty acids pptd. was small with a short-oil varnish, but considerable with a spar varnish. The proposed method, for which directions are given in detail, is briefly as follows: To approx. 4 g. of varnish add 25 cc. of H_2O and boil. Add alc. KOH and C_2H_5 and heat on the steam bath. Sep. most of the unsaponifiable matter by one extn. with Et_2O . Add HCl to the soap soln. and after recovering the fatty and resin acids, esterify by Wolff's method (cf. *C. A.* 8, 2495). Sep. the resin acids from the fatty acids ester and remaining unsaponifiable matter by treatment with KOH soln., recover and weigh. Saponify the fatty acid esters with alc. KOH, sep. the unsaponifiable matter by repeated extns. with ether, liberate the fatty acids, recover and weigh. Also recover and weigh the total unsaponifiable matter. By this procedure about 7% of the total resin content of the varnish is weighed as fatty acids, so (resin acids + unsaponifiable matter) $\times 1.07$ = resin present. The calcn. of the oil content from the fatty acids is correspondingly corrected. The method gives results which are sufficiently accurate for practical purposes. No attempt was made to sep. rosin from "gum."

E. W. BOUGHTON.

Synthetic resins. R. ELLER. *Kunststoffe* 6, 45-7(1916).—A review of the patented processes for the production of condensation products, e. g., HCHO and phenol or similar reactions.

F. W. SMITHER.

Recovering atomized colors, pigments. P. HEINRICH. *Aust.*, 70,616, Dec. 10, 1915. The pptg. color is taken up by means of a sheet of liquid formed by a flow under pressure.

Coating processes. H. B. TOONE and H. S. TOONE. *Brit.*, 22,398, May 12, 1915. A smooth surface is produced on wood, card, paper, and other materials which have been coated with ordinary oil paint or spirit varnish by placing them, after drying, in contact with a polished finishing plate and applying heat and pressure, the finishing plate being removed after cooling. A press may be used capable of being heated by steam and cooled by H_2O , and a number of coated sheets and finishing plates may be treated together in a pile. The finishing plates are preferably made of metal such as bronze or Ni, and may be plated to resist corrosion.

Coating compositions. G. CARTER. *Brit.*, 22,533, Nov. 14, 1914. An anti-corrosive coating compn., intended especially for machinery but applicable generally, consists of a soln. of 100 oz. of common rosin or colophony in 100 oz. of petroleum

spirit, with the addition of 5 oz. of liquid drier and 0.25-0.5 dram of solid spirit-sol. red.

27. FATS, FATTY OILS AND SOAPS.

E. SCHERUBEL.

Recovery of wool fat. E. E. AYERS. *Met. Chem. Eng.* 14, 317-8(1916).—*Discussion of methods of recovery:* Recently some work has been done on the commercial recovery of wool fat by centrifugal force, and there is now a centrifuge on the market which is said to be satisfactory. A scouring H_2O contg. 1.55% wool fat yielded 1.45% or 10-11 lbs. of fat per hr. at a temp. of $145^\circ F$. The purification of the product can be effected by a combination of washing and chem. bleaching agents. The elimination of odor depends on the oxidation, reduction or hydrolysis of the odoriferous substances. SO_2 and Cl give the best results as bleaching agents.

E. SCHERUBEL.

Determination of the melting point of fats and waxes. L. GOLODETZ. Hamburg. *Chem. Ztg.* 40, 223(1916).—Select a thermometer with a uniformly cylindrical bulb about 8 mm. diam. and slip through a rubber stopper. Cut pieces about 3.5 cm. long from a glass tube that will just slip over the end of the thermometer and carefully close 1 end of each piece by fusing so that the end is of uniform thickness. Weigh about 0.2 g. of the substance into 1 of the tubes, melt carefully, slip over the warmed thermometer till the bulb touches the bottom, let cool, carefully re-melt over a burner and quickly insert the thermometer into a closed glass tube about 2 cm. diam. by means of the stopper. The outer tube is to protect from air currents and allow slow cooling. Hold the tube toward the light and note the temp. at which the transparent substance suddenly becomes cloudy. This is sufficiently near the true m. p. for practical purposes. Any number of check readings may be made by re-melting the same sample.

J. H. MOORE.

Oleic acid. W. FAHRION. *Chem. Umschau* 23, 2-8(1916).—A valuable account of our present knowledge of the chem. constitution of oleic acids, 16 of which are possible by theory; 15 of these may also exist in their stereoisomeric form of elaidin acids, making a total of 31. Their general formula is $CH_3(CH_2)_nCH:CH(CH_2)_mCOOH$ with the exception of 17,18-oleic acid whose formula is $CH_3:CH(CH_2)_nCOOH$. The known 11 acids and their 3 known elaidin forms are described ranging from 2,3-oleic acid, $CH_3(CH_2)_4CH:CHCOOH$, up to 12,13 acid, $CH_3(CH_2)_4CH:CH(CH_2)_{10}COOH$, the higher ones 13,14 to 17,18 are unknown; 4 of the 11 known acids are liquid, the remainder, including the 3 elaidin forms, are solid. P. FASCHER.

Notes on the feeding and manurial value of lime seed. H. A. TEMPANY. *West Indian Bull.* 15, 27-8(1915).—Analysis showed N 1.11, P_2O_5 0.58, K_2O 0.353, moisture 9.30, crude protein 6.94, crude fat 34.44, crude fiber 17.79, crude ash 2.49, and crude carbohydrates 29.04%. An extn. with $CHCl_3$ gave an oil of dark yellow color and pronounced bitter taste, the latter being removable by washing with alc. HCl . The oil does not appear to possess any drying properties; in general, it resembles the rape oil and cottonseed oil groups. The following constants were detd.: $d_{25}^{25.8}$ 0.9160, n 1.4700, I absorption 153.9, sapon. equiv. 339.6, solidifying point $6-7^\circ$.

W. H. FRY.

Method for the determination of free caustic alkali in soap. F. H. NEWINGTON. *J. Soc. Chem. Ind.* 35, 95-6(1916).—Ten g. soap are weighed into a 250 cc. wide-necked flask; 50 cc. of boiled hot distd. H_2O are added, the flask lightly corked and heated on

a hot plate until the soap is dissolved. Next 50 cc. of a hot satd. soln. of Na_2SO_4 is added and after mixing the contents of the flask are transferred to a narrow-mouthed separatory funnel. The funnel is lightly corked and stood perpendicularly in a beaker in a hot- H_2O oven. In a short time the soap seps. on the surface while beneath is an aq. soln. of Na_2SO_4 and the free alkali, which is drawn off and titrated with 0.1 N H_2SO_4 with 5% AgNO_3 as outside indicator. As long as free NaOH is present brown Ag_2O is produced. Throughout the test the sample is very little exposed to the air and if the Na_2SO_4 and AgNO_3 are neutral there appears to be little source of error.

E. SCHERUBEL.

Analysis of waxes with special reference to beeswax and wool wax. F. W. RICHARDSON AND G. A. BRACEWELL. *J. Soc. Chem. Ind.* 35, 160-3 (1916).—The methods described are those generally used in oil and fat analysis such as detn. of acid, ester and sapon. no. with ratio of acid value to ester value. To sep. the unsaponifiable matter in beeswax R. and B. add 50 cc. of 0.5 N alc. KOH to 5 g. of the wax in a flask and evap. the mixt. almost to dryness, after which it is emulsified with boiling H_2O , transferred to a large separator and shaken out with large vols. of petr. ether. The unsaponifiable matter thus sepd. gave no trace of ash and yielded the following figures: I no. 8.0, n_{D}^{20} 1.4386, butyrefractometer at 75° 21.30. The latter will at once indicate the presence of paraffin or ceresin as the reading for these lies between 9.6 and 11.6. To det. glycerol in beeswax 5 g. of the wax which has previously been washed with hot H_2O to remove honey, are boiled with 50 cc. of 0.5 N alc. KOH in an oil flask and the alc. is then removed by heating. The pasty mass obtained is neutralized with AcOH and after diln. is mixed with excess of basic Pb acetate and filtered and the ppt. washed. The Pb is removed from the filtrate by H_2SO_4 and after concn. the dichromate method is applied. Resin can be detd. by the well-known process depending upon the relative insoly. of cerotic acid and its homologs in hot 50% alc. For the sepn. of the unsapon. matter in wool wax, about 3 g. are heated with 50 cc. of N alc. KOH , the alc. evapd. and the residue treated with a boiling mixt. of equal vols. of alc. and H_2O and while still almost at the b. p. petr. ether is added to the soln. which should be in a separatory funnel. After shaking the alc. layer is drawn off into a 2nd separatory funnel and the alc. soap soln. plunged into a boiling H_2O bath till it has attained the temp. of the bath; then the extn. is repeated. In all 7 extns. are necessary. Tables are given showing analyses of saponifiable and unsaponifiable matter of wool wax.

E. SCHERUBEL.

Action of chlorinated hydrocarbons on metals (SASTRY) 9. A large fat-extractor (SCHMIDT) 1.

• **Hydrogenating fatty acids, their glycerides and esters.** OELVERWERTUNG G. M. B. H. Aust., 70,930, Jan. 10, 1916. H is introduced with the aid of H carriers (catalyzers) such as finely divided metal oxide, carrying out the process at the ordinary pressure or under a pressure of not more than 20 atms.

Recovering fats and oils. G. BOTTARO. Brit., 22,351, Nov. 11, 1914. Trade effluents obtained in the bleaching of wool, etc., and consisting of a fatty or oily emulsion containing an insol. alk. earth sulfite, are treated to sep. fat, oil, or fatty acid by passing in SO_2 so as to transform the sulfite into a sol. bisulfite. The fat, etc., rise to the surface and may be sepd. On boiling the aq. soln., SO_2 is sepd., and the sulfite is pptd. and may also be sepd. Any sol. ingredients of the emulsion, such as glycerol, metallic chlorides, etc., may be recovered from the liquid.

28. SUGAR, STARCH AND GUMS.

A. HUGH BRYAN.

The determination of reducing sugars in the presence of an excess of sucrose. L. MAQUENNE. *Compt. rend.* 162, 207-13(1916); cf. *C. A.* 10, 980.—Data are given, showing that in the detn. at boiling temp. 10 g. sucrose affect the detn. of invert sugar at most 1 mg. M. recommends working with a fixed quantity of sugar, either 5, 10, or 20 g. If, on account of high invert content, it is necessary to work with a smaller sample, enough pure sucrose should be added to bring the total up to the usual amt. In this way, only a single entry table is necessary, as the sucrose is const. For 20 g. of sucrose, and 10 min. heating in a bath at 65°, the correction for sucrose is const. and amounts to 5 or 5.5 buret divisions of $\text{Na}_2\text{S}_2\text{O}_3$. For low invert sugar (less than 0.2%), M. recommends the following method: Mix 10 cc. each of Cu soln., tartrate soln., and H_2O , dissolve in this 10 or 20 g. solid sugar, and heat 10 min. in a 65° bath. Cool, add 20 cc. 50% H_2SO_4 , and, with vigorous stirring, 5 cc. 20% KI. Titrate with $\text{Na}_2\text{S}_2\text{O}_3$ (20 g. cryst. salt per l.) using starch paper as an outside indicator. The $\text{Na}_2\text{S}_2\text{O}_3$ soln. should be standardized weekly. The method is not applicable to molasses. If the sugar must be previously dissolved, the detn. must be made immediately, or else the soln. must be boiled for 5-6 min. to destroy invertase; otherwise the invert sugar is sometimes increased 1% in 2 days. The soln. must be cooled and titrated immediately after the heating, as 5 or 10 min. standing at ordinary temp. may increase the reduction by an amt. equiv. to more than 1 mg. of invert sugar. For concordant results, the temp. must be held const. to 0.5°, and all other conditions kept the same. Since personal equation influences the results, each one should make his own table. Sucrose free from reducing sugars may be obtained by the method of Pellet (*C. A.* 10, 538), or by 3 recrystns. from a 75% aq. soln., made at 90°. The accuracy is about 2% of the total invert sugar present. P. M. GIBBY.

Steuerwald's modification of the double polarization method, and some general observations on inversion. H. PELLET. *Intern. Sugar J.* 18, 83-8(1916).—The method described by S. (cf. *C. A.* 8, 2501) by which inversion is carried out in the cold, by allowing a quantity of HCl 3 times as strong as that ordinarily used to react at the prevailing temp., is not recommended. The ordinary method will give constant results in the hands of several chemists using the same product if the usual precautions are observed. Inversion is often found to be incomplete if the HCl is not of the required d. because of the neutralization of a large part of this hydrolyst by the excess of Pb remaining in the soln., and the neutralization of another portion by org. salts contained in the molasses or similar impure product being examd. Other sources of error attributed to the inversion are the influence of dilution, the failure to place the tube in the saccharimeter in the same position each time when examg. the liquid, and the lighting of the saccharimeter. The Andriik process is suggested for molasses, as the presence of substances of the nature of glutamine and probably asparagine do not modify the rotation when using 5 cc. or even 15 cc. concd. HCl. For 50 sugar soln., 5 cc. HCl (with 5 g. urea) should be used. A. GROSS.

The recovery of copper as sulfate from the filtrates from sugar determinations according to Fehling. KRUMBHARR. *Chem. Ztg.* 40, 174(1916).—The hot filtrates are pptd. with a slight excess of a dil. glucose soln., decanted, the Cu_2O filtered and washed free of alkali with hot H_2O , treated with concd. HCl in a covered beaker on a H_2O bath, with the addition from time to time of small amts. of H_2O_2 till oxidation is complete; evap. the soln. as far as possible on the H_2O bath, add excess dil H_2SO_4 , evap., redissolve in H_2O and evap. 2 or 3 times, filter the hot soln. into 3 vols. 96% alc., filter and wash the fine ppt. with alc. J. H. MOORE.

Some observations on the deterioration of sugars in storage. W. L. OWEN. *Louisiana Planter* 56, 173-4, 188-90(1916); cf. *C. A.* 9, 1130.—These observations confirm to a certain extent the "factor of safety" of the Colonial Sugar Refining Co., of Australia, as a criterion of the keeping quality of sugars. The factor holds that the moisture of a sugar should not be more than half of the non-sugar, or when $\text{water}/(100 - P) < 0.333$, the sugar will not deteriorate. In the case of Louisiana test sugars, 40% of the samples were safe according to this factor, and only 13% actually deteriorated. In this instance only 50% of the sugars found unsafe according to the factor actually deteriorated, which indicates that with this type of sugar a lower ratio between the non-sucrose and moisture than required by the factor need not unvariably be regarded as unsafe. Of the samples of 96 test sugars that deteriorated the av. ratio of non-sucrose was 0.450 with a minimum of 0.303, while the av. for the samples which kept well was 0.300 with a max. of 0.347. The degree of infection of a sugar with deteriorative microorganisms may invalidate the reliability of the factor of safety as a means of predicting the behavior of sugars in storage. A sugar with a factor of 0.488 ordinarily regarded as unsafe retained its original polarization during a 12-month storage period. In this sugar there were only 2200 microorganisms per g., while another containing 11,000 per g. with a factor of 0.242 deteriorated appreciably during a similar period of storage. The factor seems equally applicable to plantation white sugar. Theories regarding the nature and extent of moisture films surrounding the sugar crystals are discussed, together with the influence of bagacillo. This substance possibly hastens deterioration by maintaining a moist zone surrounding the sugar and in this way fosters the activities of microorganisms. The theory that the deterioration of sugars could be contingent upon the presence of bagacillo is held untenable, in so far as it attributes to this substance the function of supplying food for the microorganisms in sugar. Sugars which in comparison with white sugars are most bountifully supplied with nutrient material for microorganisms are the ones most likely to contain bagacillo. A. GROSS.

The use of the steam turn plate. JAMES MALLON. *Louisiana Planter* 56, 109 (1916).—Instead of water, steam is applied to the bagasse in the cane mills in the line of the turn plate. The extrn. of cane juice is accomplished without serious dilution due to the softening of the cane fibers, the ready penetration of the mass by the steam and the reduction of the viscosity of the cane juice by the higher temp. developed. Tests by this method gave 3.48% (on the basis of the wt. of the cane) of additional juice. The quality of the juice is also improved and the bagasse becomes a more ready and economic fuel due to the lower moisture content and its conservation of the heat of the steam. A. GROSS.

The manufacture of sugar in Java. J. F. CLARENC. *Intern. Sugar J.* 18, 80-2 (1916).—A description of the sugar industry of Java. A. GROSS.

Effect calandrias. CHAS. E. NEWBOLD. *Intern. Sugar J.* 18, 71-8(1916).—A practical description with suggestions for increasing efficiency. A. GROSS.

Starch and dextrin. A review of patents for the last nine years. R. M. WOLF. *Chem. App.* 3, 52-4(1916).—German patents to Nov., 1915. J. H. MOORE.

Sugar cane mills. J. WILSON. *Brit.*, 22,390, Nov. 12, 1914. A sugar cane or like mill is built up with a series of pairs of rollers mounted on an inclined frame. The pairs of rollers are set parallel and inclined at the same angle to the frame, and the roughness of the surface of the rollers decreases with each pair, while the pressure in-

creases. The last pair of rollers may be either both smooth, or the lower smooth and the upper one finely grooved.

Betaine and betaine salts. AKT.-GES. FÜR ANILIN-FABRIKATION. Aust., 70,875. Jan. 10, 1916. In the manuf. of betaine or betaine salts from molasses, molasses washings, or other end liquors from beet sugar manuf., the initial material is freed from H_2O as completely as possible, then mixed with HCl , while avoiding overheating so that, *e. g.*, a temp. of $50-60^\circ$ is not exceeded, and the betaine- HCl is cooled to crystn., the sepd. crude salt being purified in the known manner, as by resoln. in $MeOH$ and evapa., or by recrystn. from H_2O .

29. LEATHER AND GLUE.

LLOYD BALDERSTON.

Barium in the leather and allied trades. Its history, occurrence, manufacture, use in the leather industry, and the testing for it. FRED ASHWORTH. *Leather Manuf.* 27, 2, 43-5 (1916).
J. S. ROGERS.

Tanning substitutes. W. EITNER. *Gerber* 41, 263 (1915).—As substitutes for the unobtainable tanning substances, E. enumerates *Rhus cotinus*, from Southern Tyrol, Dalmatia and Herzegowina, whose leaves, gathered immediately after the flowering stage, contain up to 18% tannin. During the Napoleonic wars a book, "Ausführlicher Beschreibung der Lohgerberei," by Ignaz Bautsch, a tanner in Wurtemberg, was published (1796) in Dresden, which contains a list of many plants useful as tanning substitutes or auxiliaries. E. has elsewhere described members of the Ericaceae, *e. g.*, the bilberry and the cranberry, and a few vaccinia, which contain tannin, both in leaf and stem.
W. B. J.

The war and tanning requirements. E. GLÜCKSMANN. *Gerber* 41, 197 (1915).—Syntans can largely replace the tannins unobtainable because of the war. Five to 15%, based on the wt., of the raw hide, of Neradol D following sumac tanning, quickly gives good leather from sheep and goat skins. Upper leathers and all kinds of heavy leathers can be tanned either in the drum or vat, with Neradol D, and all vegetable tannins, in less time, and with greater yield. With heavy leathers, 1 to 2° Bé. solns. of Neradol D are used. The advantages of the different neradols, with and without vegetable tans, are further discussed.
W. B. J.

The leather industry of the Philippine Islands. VINCENTE Q. GANA. *Philippine J. Sci.* 10A, 349-71 (1915).—A study of the resources of the islands for leather manuf. and of the methods in use, with special reference to remediable faults in methods. There are 167 tanneries in the islands, the yearly output being about 93,000 tanned hides. Statistics of imports, exports and prices are given. The method of tanning used is that introduced centuries ago by the Chinese. Beside native hides, some Australian hides are used, and more from China. A large proportion of the hides taken off in many parts of the islands are wasted. The tanning materials used are mangrove bark of several species and the bark of *Pithecolobium dulce*, called camanchile. Mangrove is used only in Manila, the native tanners generally preferring camanchile, although its price is very high, reaching \$40 per ton, because of the lighter color of the product. Analysis of camanchile shows (dry basis) tannin 25.4, non-tannins 9.4%. Some nitrogenous matter is present, which may account in part for the growth of putrefactive organisms in the tan-liquors. Analyses are given of a number of other materials which have been proposed as possible sources of tannin. None which is available in quantity has enough tannin to make it useful. The camanchile bark is

prepd. for use by chopping it into pieces 3-4 cm. in size. A sample of spent bark showed more than half as much tannin as the new bark. Hides are soaked for a few hours in water and then limed from 10 to 15 days, with 3 or 4 haulings. After being unhaired and fleshed they are washed for a few hours in running water and placed in pits with liquor and bark. Once a day for 4 days the packs are shifted and the hides kneaded with bare feet to aid in the penetration of the tannin, which by the end of this time amounts to $\frac{1}{2}$ the thickness of the hides. If evidence of putrefaction is found, a 5th or even a 6th handling is given. In the rainy season some tanners shut down because of the difficulty in preventing the hides from putrefying in the first stage of tanning. After being taken from the handlers, the hides are laid down in other pits with liquor and bark for 6 weeks to complete the tannage. After washing, the leather is dried in sunshine and sold without further treatment. Losses from putrefaction are great. Much tannin is wasted, and the product is very much under-tanned. One cause of poor results is the use of unsuitable water. Analyses of 3 waters are given. Lack of cleanliness is partially responsible for putrefaction in the liquors. Putrefactive bacteria were found in both weak and strong liquors. In this respect infusions of camanchile bark differ from those of other familiar tanning materials. Several analyses of liquors at various stages of the process are given. The percentage of tannin is low in all. G. tried an expt. in one of the Philippine tanneries, using ten hides, which were placed for 24 hrs. in a 1% soln. of phenol after being unhaired, fleshed, and partially delimed with H_2SO_4 . In the later stages stronger liquors were employed, and the whole time in the liquor was increased to 12 weeks. The leather was oiled, rolled and dried in the shade. The wt. of leather produced was 32% greater than that from similar hides tanned by the native process and its quality much higher. In another expt. some mangrove bark was used in the layers, the product being of good quality and orange brown in color.

L. B.

Potassium titanium oxalate as a dye, stainer and mordant. FRED ASHWORTH. *Leather World* 8, No. 2, 15-6(1916); *Shoe and Leather Reporter* 121, No. 9, 77-9(1916).—Ti salts in conjunction with tanning materials form a yellowish brown lake which is fast to light and to the action of alk. salts. It is used in the dyeing of both chrome and vegetable tanned leathers. A shade of yellowish brown tan suitable for strapping purposes may be produced by dissolving 2 oz. of K Ti oxalate in 1 gal. of water and applying with a brush. K Ti oxalate has an advantage over tartar emetic as it not only fixes the tannin on the leather, thus preventing staining in the dye bath, but on account of the yellowish brown color lake, much less dyestuff is required. A large variety of shades can be obtained by its use with dyewood exts. Formulas are given for light yellow, light yellowish brown, sugar loaf brown, brown, chocolate, red, crimson, scarlet, olive green, brown, and reddish violet. Bright blue cannot be obtained as the yellow color would produce bluish greens. Satisfactory shades may be produced without the use of coal-tar dyes or with only a little added to make the shade a trifle "livelier." One advantage is that the color is regular throughout the whole of the skin. The goods may be fat-liquored after dyeing. Wood vessels are preferable to copper, as the latter lead to a darkening of the color, and are injurious to the basic coloring matters.

J. S. ROGERS.

Dressing pig skins. I. E. MORTON. *Leather World; Hide and Leather* 51, No. 10, 25-6(1916).—Pig skins are almost without exception tanned with oak bark, and require a light prepn. for dressing. They are, as a general rule, shaved by hand, lightly boraxed, washed, scoured, washed, and sumaced, washed, struck out, set and strained. For color work, the straining is done after the dyeing. They must not be tallowed before dyeing. For London Color, the skins should be sorted and then stained, usually

with an annatto in an alk. or alc. soln. Suitable dyes are Golden brown Y, Cuba yellow, croceine AZ, phosphine substitute, tartrazine, turmeric substitute, sun yellow G, titan yellow Y, titan orange, and resorcine brown. One-quarter oz. of any of these dyes is dissolved and made up to one gal. Six lbs. of gum tragacanth are dissolved in 60 gal. cold water with 4 oz. oxalic acid. Two pints dissolved gum and $\frac{1}{2}$ pint of dye are taken and made up to 4 gals. The skins are given two good brushings, horsed up and set. Hand stuffing is done by brushing the grain side with dubbin. The skins are then hung up and dried in a cool place, trimmed and slicker whitened on the flesh side, pebbled on the grain side, and grained in almost any direction. They are then flattened by graining on the flesh side, and finally brushed on the grain. Paraffin wax will give a bright face. A suitable mixt. for drum dyeing is 8 oz. tartrazine, 8 oz. resorcine brown, and 16 oz. formic acid for 3 doz. medium sized pig skins. Dye for an hour, run off water, wash with drum in motion, drain and examine. They must be warm for stuffing. A good stuffing mixt. is 6 parts stearin, 2 parts hard tallow, and 2 parts cod oil. Allow $\frac{1}{2}$ the quantity of stuffing to the dry wt. of the goods. The paddle is preferred to the tray or drum for dyeing as it is cheaper and the goods can be watched and do not need handling. The chief colors required are yellows and tan browns. Lime water should be neutralized by acetic acid. Practical recipes are given for tan shade in the drum, browns medium, light, medium and dark green, maroon, blue, and black, and the method of dyeing described in detail. Acid colors give a more even and clean result than basic. The Russian smell may be imparted in various ways. M. prefers spraying a mixt. of birch tar oil and whale oil on to the skins when they are hanging up. Pig skins for saddles are soaked in linseed oil. J. S. ROGERS

Report of committee on miscellaneous methods. L. BALDERSTON. *J. Am. Leather Chem. Assoc.* 11, 95-8(1916).—Estn. of volatile acid in lactic acid was studied. A standard method of distn. is suggested, and results of distg. mixts. containing up to 3% of CH_3COOH are given; also a table showing amts. of volatile acid in distg. flask corresponding to amts. up to 70 mg. found in distillates. L. B.

The use of nickel hydroxide in tannin estimation. PURAN SINGH AND T. P. GHOSH. *J. Soc. Chem. Ind.* 35, 159-60(1916).—As supplies of hide powder sometimes run short in India it is desirable to secure a substitute. It is difficult to prepare $\text{Ni}(\text{OH})_2$ free from sulfate in paste form. Kahlbaum's extra pure $\text{Ni}(\text{OH})_2$ contained traces of sulfate. After repeated washing with hot water and finally with water containing traces of tannic acid, it was free from sulfate and in a fairly granular condition. The $\text{Ni}(\text{OH})_2$ was used in this form. Babul pods by the $\text{Ni}(\text{OH})_2$ paste method give 26.3% tannin, by the hide powder method 23.7%, and by the Cu acetate method 26.6%. Solns. of tannic acid, gallic acid, glucose, and cane sugar of known strength were treated with chromed hide powder and with $\text{Ni}(\text{OH})_2$ under similar conditions, and encouraging results were obtained. The table of results is given. Comparative estimates were then made with a number of tanning materials, the results of which are given. Instead of hide powder, 20 g. $\text{Ni}(\text{OH})_2$ free from water should be added for detannization. The authors are using this $\text{Ni}(\text{OH})_2$ method and consider it as reliable as and perhaps preferable to the hide powder method considering that $\text{Ni}(\text{OH})_2$ is a standard substance and can be used wherever org. and mineral acids likely to dissolve $\text{Ni}(\text{OH})_2$ are not present. In the discussion Procter said that this method could not take the place of the hide powder method commercially but there was no reason why it should not be used as a preliminary method in forming judgment for forestry purposes. $\text{Al}(\text{OH})_3$ has been used with good results. Cu gives considerable accuracy with some tannins, but many tannins give ppts. which are sol. in ammoniacal copper solns.

J. S. ROGERS.

Analysis of Dutch, English and American sole leathers. ANON. *Hide and Leather*; *J. Am. Leather Chem. Assoc.* 11, 167-70(1916).—De Nederlandsche Leder-industrie has published an article giving comparative analyses of Am., Dutch, and Eng. sole leathers. In none of these countries do tanners still use pure oak bark exclusively. The use of exts. in drum tannage is much quicker but the quality of leather is not improved. Oak-tanned sole leathers contain only 8-10% of water-sol. materials. With mixed tannage this percentage is higher, while with pure ext. tannage it is still higher, the av. being 18.6% for Dutch ext. tanned sole leather according to expts. by the Govt. Expt. Station at Waalwyk, Holland. The English Federation of Tanners recently decided on 25% as the limit. Figures are given showing the results of 32 analyses of Dutch sole leather. They show 11.3% sol. org. materials and 19.4% moisture. The results of analyses of 3 English leathers are given. One was a good tannage, having 21.1% sol. org. materials. The others were of leather of the quick tanning method as it is now made to satisfy the urgent demand. They contain 31.4% and 32% sol. org. materials. Analyses results are given for 6 Am. leathers. The worst of these was a sole leather of a large corporation and so-called "scoured bends." It sold for 59 cents a lb., had 31.2% sol. org. materials, 2.7% ash, 9.76% sugar, 4.85% Epsom salts, and 18.66% combined tannin (indicating quick tannage with strong materials). This leather looked all right on the grain, thus indicating that American leather cannot be judged by its looks. Far superior to this was a hemlock-tanned sole leather (from a leading producer) which sold for 49 cents a lb. The best sample was an oak-bark tanned product of Kentucky, tanned by the old system. The price was 59 cents a lb. It contained 22% sol. org. materials, but only 12.68% moisture. The two samples next in quality were normal excepting in sugar content. They contained 3.42% and 2.5%, respectively, while only 2% is allowed. One of these sold for 55 cents a lb.

J. S. ROGERS.

Analysis of tannery lime liquors. H. G. BENNETT. *Collegium (London)* 1915, 258-66, 313-22, 329-35; *J. Am. Leather Chem. Assoc.* 11, 98-130.—(1) *Alkalinity:* Methyl orange or phenolphthalein may be used for rough control work, though neither gives accurate results. Alizarin paste is a better indicator, being sensitive to weak acids and suitable for the titration of ammonia. It should be added near the end of the titration, as its Ca salt is insol. Half of the Na present as sulfide is detd. along with other alkalis. Two other methods for total alkalinity of liquors containing sulfide are given: indirectly by boiling with excess of 0.1 N H_2SO_4 till H_2S is expelled and titrating the excess, and directly by titrating with 0.1 N acid and methyl orange after pptg. peptone matters held in soln. by alkalis by means of H_3BO_3 and filtering. Methyl orange is not affected either by H_3BO_3 or H_2S . (2) *Ammonia:* As long as the liquor is boiled, NH_3 continues to be given off, in consequence of gradual decompn. of org. matter present. The distn. must therefore be stopped at some arbitrary point. To check liberation of NH_3 20 cc. of a 10% soln. of $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ are added to 100 cc. of lime liquor before distg., and the mixt. is distd. exactly 15 min., the NH_3 being collected in excess of boric acid soln. and titrated direct with 0.1 N HCl and methyl orange. If ZnSO_4 soln. be substituted for MgSO_4 , the pptn. of nitrogenous matter is more complete. (3) *Sulfides:* The method recommended employs a soln. of ZnSO_4 with NH_4Cl and NH_3 with Na nitroprusside as external indicator (*C. A.* 7, 716; 8, 3135, 2505). (4) *Soda:* A measured amt. of filtered liquor is evapd., ignited, the residue moistened with $(\text{NH}_4)_2\text{CO}_3$ soln. and gently ignited. The residue is washed on a filter and the filtrate titrated with 0.1 N HCl and methyl orange. (5) *Lime:* (a) *Total lime:* Evap. 25 cc. of filtered liquor, ignite the residue and dissolve it in HCl. Ppt. Ca as oxalate, wash and dissolve in dil. H_2SO_4 and titrate with 0.1 N KMnO_4 at 70°. (b) *Caustic lime:* Three methods are discussed, and their errors pointed out.

B. prefers a fourth, in which the liquor is treated with HCHO before titration. HCHO reacts with NH_3 to form hexamethylenetetramine which is neutral to phenolphthalein. It also reacts with hydrosulfides, converting them into hydroxides. There is thus no error due to the escape of H_2S , but the alkalinity to phenolphthalein is increased. HCHO also reacts with amino acids present in the liquor, forming acids which affect the indicator, thus reducing the alkalinity. Such reduction may be determined separately by a method suggested by Stiasny (*C. A.* 5, 1004). To 10 cc. 40% HCHO add 10 cc. H_2O , and neutralize to phenolphthalein with 0.1 *N* NaOH. Add 25 cc. filtered lime liquor and titrate with 0.1 *N* HCl. *Stiasny's correction:* Neutralize 25 cc. filtered liquor to phenolphthalein with 10% AcOH. Add 0.1 *N* I to slight excess, then 10 cc. 40% HCHO, neutralize, and titrate again with 0.1 *N* NaOH. The 2nd titration is a measure of the amino acids present in the original liquor. If sulfides and NaOH have been detd., it is now possible to calc. the $\text{Ca}(\text{OH})_2$. (6) *Nitrogenous material:* The Kjeldahl method is satisfactory. Six possible causes of error are discussed. The Ronch  e method is recommended for estg. the NH_3 ; after digestion exactly neutralize excess H_2SO_4 with NaOH, and add excess of neutral HCHO, which converts NH_3 to hexamethylenetetramine, liberating an equiv. amt. of H_2SO_4 , which is titrated with 0.1 *N* NaOH. (7) *Sodium chloride:* (a) *Indirect.* Sulfides and much of the organic matter are thrown out with $\text{Zn}(\text{NO}_3)_2$. The filtrate is oxidized with HNO_3 and a definite amt. of 0.1 *N* AgNO_3 is added; pptd. AgCl filtered off, and excess of AgNO_3 titrated with KSCN, ferric sulfate indicator. (b) *Direct.* Sulfides, NH_3 , and much organic matter are thrown out by boiling with $\text{Mg}(\text{NO}_3)_2$, which leaves the liquid neutral, and permits the usual titration with AgNO_3 , K_2CrO_4 indicator. The direct method is less satisfactory because of incomplete removal of org. matter which causes too great consumption of AgNO_3 .
L. B.

Artificial leather and leather substitutes. R. LAUFFMANN. *Kunststoffe* 6, 41-3 (1916).—A discussion of processes patented during the past 2 yrs. in Germany (cf. Kausch, *C. A.* 8, 1885; Micksch, *C. A.* 9, 1258, 1553, 2606). F. W. SMITHER.

Leather. REBERLE & Co. Brit., 22,753, Nov. 19, 1914. Hides are bated by means of a material obtained by the decompn. of animal organs by the enzymes contained therein or by peptolytic enzymes; pancreatic gland, liver, gall, bowel, etc., are suitable starting materials; other albuminous substances such as meat, glue, casein, etc., may be added; when decompn. is complete, the mass is heated to destroy the enzymes, and the liquid portion of the product is sepd.; it may be used as such or absorbed in kieselguhr, sawdust, etc.

Artificial leather. N. G. SCHUEER. Brit., 100,038, Jan. 24, 1916. Artificial leather is made by impregnating linen duck with linseed oil or a varnish to which a little siccative and Vienna red have been added, drying and sticking sheets of this material together with a mixt. of 4 kg. heated wood-tar pitch, 2 kg. India rubber dissolved in benzene or the like, 4 kg. Vienna red mixed to thick consistence with French turpentine, and 2 kg. of powdered cork. The compd. sheet is finally passed through pressure rollers.

Artificial sole leather. O. LINDNER. Aust., 70,943, Jan. 10, 1916. The fibrous material serving as initial material, such as hair mat, wool fiber, or the like, is subjected first to a petrifying process by satn. with sol. silicates, finally in the presence of substances containing lime or silica, the plates obtained from this material by rolling it out, are rendered water-tight and flexible, after drying, by immersing them in mixts. of resin solns. with glycerol, and these plates are then impregnated with

a melt of resinous wax-like or fatty acid-like substances or mixts. of these. Cf. C. A. 9, 1857.

Linoleum soles for boots and shoes. I. FIZIA. Aust., 70,609, Dec. 10, 1915. The soles are built up of layers of linoleum and fabric, cemented together with shoe-makers' cement and enamel varnish.

Tannin-colored etchings with vat dyes. KALLE & CO. Aust., 70,946, Jan. 10, 1916. The tanned material, before printing with the color etch, is prepd. with Al acetate.

Tanning and impregnating. ELEKTRO-OSMOSE AKT.-GES. Aust., 70,915, Jan. 10, 1916. The liquid containing the active substances is subjected, between diaphragms, to the action of the elec. current. Circulation of the liquid is facilitated by stirring, or the like.

Tanning and cleaning the tanning material simultaneously. ELEKTRO-OSMOSE AKT.-GES. Aust., 70,916, Jan. 10, 1916. In the application of the process of 70,915 (*supra*), an electro-osmotic purification process for the tanning substance is combined with the tanning process.

Glue and gelatin. C. TWELE. Aust., 70,944, Jan. 10, 1916. Alum leather scrap or the usual leather parings for size are treated with a NaCl soln. After washing out the NaCl, and boiling, a neutral glue liquor is obtained.

30. RUBBER AND ALLIED SUBSTANCES.

R. T. STOKES.

Investigation of caoutchouc-like products. ALFONS LANGER. *Pharm. Ztg.* 61, 14(1916).—The examn. of 2 samples of caoutchouc substitutes revealed the presence, among other things, of naphthalene and a saponifiable material yielding glycerol and fatty acids, of odor resembling that of oleic acid. W. O. E.

Prevention of the harmful effects of ultraviolet light on balloon fabric. THEODOR SCHOPPER. Berlin, Neukoelln. *Gummi-Ztg.* 29, 1250(1915).—Inspired by Ger. Pat. 286,260, on the coating of balloon fabric with yellow pigment, Al powder, or both. S. describes expts. which show that the action of light on sensitized paper is almost completely prevented by the addition of $1/100000$ th part of β -methyl-dihydroxycoumarin or a 1% soln. of dimethylamino- β -methylcoumarin to a colorless lacquer on a glass plate covering the paper. A spot of tender skin covered with a very weakly alk. 15% soln. of β -methylhydroxycoumarin in glycerol was not sun-burned, while a spot next to it covered with glycerol only was badly burned. These materials have the further advantage of low gravity and could be used as pigments to color the balloon fabric.

E. L. D.

Prevention of harmful effects of ultraviolet rays on balloon fabrics. C. MANNICH. *Gummi-Ztg.* 30, 349(1916).—M. claims that Schopper's discoveries on this subject (cf. preceding abstract) were anticipated by him, and are protected by Ger. patent No. 253,334 (cf. C. A. 7, 433). R. T. S.

Tackiness of crude rubber. K. GORTER. *Gummi-Ztg.* 30, 351(1916); *Caoutchouc et Gutta-percha* 12, 8721-2(1915).—According to Spence tackiness is caused by a breaking down of the caoutchouc mol. G. exposed samples of caoutchouc in sealed tubes to the action of light, the tubes being filled with air, CO₂, O, and H, respectively. The caoutchouc became tacky only in those tubes which contained O and air. The oxidation proceeded slowly the first 6 days, then more rapidly, reaching

a max. in about 30 days. Rubber boiled in H_2O oxidized under these conditions also, proving that tackiness is not caused by enzymes, as claimed by Whitby (*C. A.* 7, 2318). The presence of aldehydes in the tacky rubber was established. R. T. S.

Reclaimed rubber. M. WACHTER. *Gummi-Ztg.* 30, 373-4(1916).—A rambling discussion of the manuf. and uses of reclaimed rubber. W. grants that American reclaimed rubber is in general superior to the European product, for the reason that the rubber scrap in America is better than European scrap, containing less factice. W. considers reclaimed rubber especially suited for elec. insulation, and protests vigorously against the prohibition of its use by specification writers. [W. is an authority on cable manufacture.—ABSTR.] R. T. S.

Indigenous rubber plant, high in rubber content. J. SCHILLER. *Gummi-Ztg.* 30, 500-1(1916).—Discussion of *Laetuca viminea*, a plant which flourishes in the Danube and Elbe valleys, and which grows to a height of 1 to 2 m. The "latex" yields a weak rubber, analyzing 19.06% of resin and 73.21% of caoutchouc. The % of rubber, calcd. against dry material, is 0.49, the yield being higher in cultivated than in wild plants. S. points out that the annual yield from *Hevea brasiliensis* and *Kickxia elastica* is only 0.3% on a dry basis. *Parthenium argentatum* yields 10%. The article must be regarded as the theoretical ideas of a biologist, rather than the practical consideration of a rubber expert. R. T. STOKES.

Porosity of rubber. ANON. *Gummi-Ztg.* 30, 456-7(1916).—Porosity of rubber, in a technical sense, may be due to several factors. Surface porosity is usually caused by condensation of steam on the goods during vulcanization. If the goods are embedded in talc, the drops of H_2O percolate through the talc to the rubber and cause uneven vulcanization. Höhn (*Gummi-Ztg.* 14, 423) suggested that this danger might be obviated by slightly moistening the entire surface of the talc before the heater is closed. In the case of goods which are wrapped before vulcanization, moistening the wrapper will prevent blowing. Internal porosity is caused by moisture in the rubber or compound, by the use of a low-grade weak rubber in whole or in part, or by over-milling the stock in "breaking down" or compounding. Porosity in molded goods is due to the fact that the mold was not completely closed, or that insufficient stock to fill the mold was taken. R. T. S.

The storage of rubber goods. ANON. *Gummi-Ztg.* 30, 402-3(1916).—Light, high and low temps., and moisture tend to shorten the life of rubber goods. Blue and violet light rays are particularly harmful; red light is practically without effect. The color of the goods seems to have some influence, bright colors acting to some degree as preservatives. The S "bloom" may have a certain protective effect. R. T. S.

Hard rubber and other electrical insulation. ANON. *Gummi-Ztg.* 30, 499-500(1916).—A description of methods of making-up and curing sheet, rod, and molded articles, of the prepn. of hard rubber dust, etc. R. T. S.

The manufacture and use of reclaimed rubber. ANON. *Gummi-Ztg.* 30, 147-9(1915).—Discussion, under the following captions: What is reclaimed rubber; what brought about its manuf. and use; should the rubber goods factory run its own reclaiming plant, or leave reclaiming to the reclaiming industry? The author inclines to the latter view. The article contains nothing new. RAXLEY F. WESSER.

The resin content of rubber. F. JACOBSON. *Gummi-Ztg.* 30, 5-6, 28-30, 53-6(1915).—A comprehensive compilation from the literature of a mass of information regarding the resins of various sorts of rubber and gutta-percha, their source, compn. and nature, the conflicting views as to their significance, their role in vulcanization, etc. The following related subjects are also considered: compn. of rubber latex, theories

of coagulation, causes of tackiness, technical uses of resins (particularly of Pontianak resin). A bibliography is included.

RAXLEY F. WEBER.

Determination of barium carbonate and barium sulfate in rubber goods. J. B. TURRLE. *Bur. Standards, Tech. Paper No. 64*, 5 pp.(1916); *J. Ind. Eng. Chem.* 8, 324-6(1916).—Since the presence of BaCO_3 interferes with the detn. of total S in rubber goods, a method for its detn. is needed. T.'s method is as follows: Heat 1 g. of the sample in the app. described by Schaeffer (cf. *C. A.* 7, 906), passing a current of CO_2 through the tube. After ignition, remove the boat containing the sample and transfer it to a 250 cc. beaker. Treat with 5-10 g. of $(\text{NH}_4)_2\text{CO}_3$, 15-20 cc. concd. NH_4OH and 50 cc. H_2O . Boil for 15 min., filter and wash. Wash insol. matter back into beaker and treat with 10 cc. glacial AcOH and enough H_2O to bring the vol. of the soln. to about 100 cc. Boil and filter. Pass H_2S through the filtrate, filter off the PbS , wash and det. Ba in filtrate by pptn. with H_2SO_4 and weighing as BaSO_4 . $\text{Wt. BaSO}_4 \times 0.845 = \text{BaCO}_3$. Analysis of mixts. of known compn. showed the method to be reliable.

E. W. BOUGHTON.

A method for the direct determination of rubber in a compound. R. W. BELFIT. *J. Ind. Eng. Chem.* 8, 326-7(1916).—The method is applicable only to high-grade compounds which are free from org. substitutes of every description. Instead of converting rubber into a nitrosite as Wesson does (*C. A.* 8, 2815), B. treats the acetone-extd. sample with boiling HCl , and burns the residue in a combustion tube after washing out HCl and drying in CO_2 . From the wt. of CO_2 obtained from the combustion, the % of caoutchouc is calcd. Two detns. on fine Para gave 96.19% and 96.57%; and in the analysis of 4 "30% compounds," results checking remarkably well with the theoretical figures were obtained.

R. T. S.

Action of chlorinated hydrocarbons on metals (SASTRY) 9.

India rubber. S. C. DAVIDSON. *Brit.*, 22,138, Nov. 6, 1914. Rubber latex is coagulated by adding an "alkalized" cresol, cresylic acid or higher tar acids, or other "alkalized" phenol, as described in 11,470, 1912 (*C. A.* 7, 3673), and 13,438, 1913 (*C. A.* 8, 3867), and an aq. soln. of a thio sulfate, sulfite, or other compd. capable of evolving SO_2 on treatment with acid or acid substance, and finally coagulating by adding an acid or acid substance to liberate the preservative substance in the phenol and also to liberate SO_2 .

Kneading India rubber. S. C. DAVIDSON. *Brit.*, 22,490, Nov. 13, 1914. Machines for kneading, and at the same time, if desired, for drying or washing, rubber, etc., consist of a number of rollers assembled so as to form a cavity in which the rubber is rolled over and over.

Coagulating rubber latex. S. C. DAVIDSON. *Brit.*, 22,489, Nov. 13, 1914. Latex is coagulated by the addition of dil. acid or other coagulant during its oscillation in a specially shaped churn or receptacle. The latex is contained in a vessel having its ends curved over inwards, and with an open top. The vessel is attached to links pivoted so that it can be oscillated by any suitable means. A tank contains the coagulating liquid, which flows through a measuring vessel into the latex vessel. When coagulation is finished, a catch holding the said latex vessel is released, and the vessel turned over so that the liquid flows through a screen on to a deflecting shoot, the rubber being retained on the screen. The vessel is then turned over on the opposite side and the rubber emptied onto another discharge shoot on the opposite side of the center line of the app.

3-Methylbutenol, its homologs and analogs. BAYER & Co. Aust., 70,880, Jan 10, 1916. 3-Methylbutenol, its homologs and analogs, are obtained by treating 3-methylbutinol, as well as its homologs and analogs, with reducing agents. The products have technical value inasmuch as isoprene and its homologs and analogs can be obtained from them by the removal of H_2O . The reducing agents specified are Na, Zn dust and HOAc, Zn dust and H_2O ; colloidal Pd, and Ni.

Published by the American Chemical Society, Easton, Pa.

Entered as Second-class Matter at the Post-Office, Easton, Pa.

Communications for the Editor should be addressed to E. J. Crane, Ohio State University, Columbus, Ohio.

The Council have voted that no claims for copies lost in the mails can be allowed, unless such claim is received within "sixty days" of the date of issue, nor if due to failure to give sufficient notice of change of address. Charles L. Parsons, Secretary.

Remittances for annual membership dues or for subscriptions, changes of address, orders for subscriptions or back numbers, claims for missing numbers and all matters intended for the Proceedings should be sent to the Secretary, Charles L. Parsons, Box 505 Washington, D. C.

Secretary's Office: Box 505, Washington, D. C.
Eschenbach Printing Company, Easton, Pa.

The American Chemical Society

The Board of Directors of the American Chemical Society has fixed the following schedule of prices for its publications:

Subscription Rates

Journal American Chemical Society.....	\$6.00
Chemical Abstracts.....	6.00
Jour. Industrial and Engineering Chemistry.....	6.00
Two Journals to same address.....	10.20
All three Journals to same address.....	12.60

Back Numbers and Volumes

	To Members	To Non-members
Single Numbers: J. A. C. S.; J. I. E. Chem. or Chem. Abs. . .	0.50	0.60
Proceedings, Vol. 1 (1876); Vol. 2 (1877).....	2.00	2.50
Back volumes { J. Am. Chem. Soc., Vols. 1-16 inclusive, each..	4.00	5.00
J. Am. Chem. Soc., Vols. 17-37 inclusive, each	5.00	6.00
Chem. Abs., Vol. 1, 2, 3 or 5 complete, each . .	10.00	12.00
Chem. Abs., Vol. 4, 6, 7, 8 or 9 complete, each .	5.00	6.00
Index to Vols. 1-20, J. Am. Chem. Soc.....	0.50	0.75
Index to Chem. Abstracts, Vol. 1, 2, 3, 4, 5, 6, 7, 8 or 9....	1.00	1.00
Jour. Ind. and Eng. Chem., Vols. 1-7.....	5.00	6.00

Foreign Postage, each Journal 75c; Chemical Abstracts, \$1.00 a year.

Special Discounts to Newsdealers, Libraries and Institutions of Learning

Complete sets, Vols. 1 to 37, of the Journal; Proceedings, Vols. 1 and 2; Vols. 1 to 9 of Chemical Abstracts; and Vols. 1 to 7 of the Jour. Ind. and Eng. Chem., may be had of the Secretary.

The following numbers can be furnished only in complete sets, viz.: J. Am. Chem. Soc., 17 (1895), 1-6, 8, 9 and 11; 18, 5; 19, 1 and 4; 20, 3; 22, 4, 9, 10 and 11.

Besides the above, the following numbers can be furnished only in complete volumes, viz.: J. Am. Chem. Soc., 26, 4; 29 (1907) 4, 7 and 9; 30 (1908), 4, 5, 6 and 7; 38 (1916), 1 and 2; Chemical Abstracts, 1 (1907), 2, 3, 12, 13, 14, 15, 16 and 22; 5, no numbers except 1, 4 and 6; 7, 24; Jour. Ind. and Eng. Chem., 1, only No. 11; 2, 12; 3, only Nos. 2 and 8; 4, 3, 4, 5 and 10; 5, 1; 6, 5, 6 and 8; 7, 1 and 8; 8 (1916), 1 and 2.

Advance payment is required and should be made by check or money order only

The Council has voted that the Secretary shall honor claims for non-receipt of publications only if received within sixty days of their issue. Claimants must also directly state that the publication was not delivered at their recorded address. "Missing from files" is no proof of non-receipt.

The Society will not be responsible for loss due to change of address unless notification is received one week in advance of issue.

Members or subscribers desiring their Journals or Abstracts forwarded from an old address should always notify their Postmaster and leave necessary postage.

The names of members and subscribers, whose Journals or Chemical Abstracts cannot be delivered by the Post-Office Department, will be cut off the mailing list at once, and will not be restored until correct addresses have been furnished.

In the absence of other information, the notices of change of address received from the Post-Office Department will be considered as correct, and the mailing list changed accordingly.

All communications should be addressed to

CHARLES L. PARSONS, Secretary,

Box 505, Washington, D. C.

15. Soils and Fertilizers	1390		

PATENTS

Abstracts of patents are included under the appropriate divisions of the journal, those on organic compounds, unless they pertain especially to some other division, are under Pharmaceutical Chemistry. The abstracts of U. S. patents are prepared by Earl T. Ragan, those of Canadian patents by Russell S. Smart, of Fetherstonhaugh & Smart, Ottawa (50 Queen St.), and all others by O. D. Swett. Most German patents are prepared, with permission, from the abstracts in *Chemiker-Zeitung* and Italian patents from those in *Annali di chimica applicata*. All other patents are obtained direct from the specifications.

Copies of any patent may be obtained for: United States, 5 cents, sent to the Patent Office, Washington, D. C., French; one franc, sent to L'Imprimerie Nationale, 87 rue de Vieille du Temple, Paris; German, one mark, sent to the Patent Office, Berlin; British, eight pence, sent to Patent Office, London (extra postage, outside United Kingdom); Austrian, write to the Patent Office, Vienna; Danish, write to the Patent Office, Copenhagen; Norwegian, 1 crown, Patent Office, Christiania; Swedish, 1 crown, Patent Office, Stockholm. Of Canadian patents, manuscript copies only are obtainable. They may be secured from Fetherstonhaugh & Smart, or the Commissioner of Patents direct. Estimates of cost may be obtained in advance.

In ordering a copy of a patent, the number of the patent, name of the patentee, and subject of the invention should be stated.

CHEMICAL ABSTRACTS

Vol. 10.

MAY 20, 1916.

No. 10

I. APPARATUS.

L. C. JONES.

Simple vacuum distilling apparatus. T. G. GREAVES. *J. Am. Leather Chem. Assoc.* 11, 172-3(1916).—For the app. having a glass dome joined to the lower part by a rubber gasket, extra parts for which cannot now be obtained, G. substitutes a glass jug of about 4 l. capacity, set in an outer metal vessel. L. B.

Pocket carbon dioxide indicator. ANON. *Eng. Mining J.* 101, 647(1916).—The app., designed to det. the amt. of CO_2 in flue and furnace gases, is constructed with an upper and lower bulb; the latter is filled with KOH, one filling sufficing for 200 detns. About $2\frac{1}{2}$ min. are required for a test. *Operation:* A sample of gas is pumped in through a cock above the upper bulb; a lower cock is then turned 180° to permit the gas and KOH to come in contact. The lower cock is closed, and the app. is inverted and immersed in H_2O ; the upper cock is then opened, and H_2O flows in to take the place of the absorbed CO_2 . Closing what was the top cock and bringing the app. to its normal upright position, the percentage of CO_2 is read off on the graduated tube at the H_2O level. The H_2O is then poured out through the top cock, and the app. is ready for another test. The app., manufd. by the Bacharach Industrial Instrument Co., Pittsburgh, Pa., is of small wt. and with case fits one's pocket. F. W. SMITHER.

Practical cock keys. F. W. HORST. *Chem. App.* 3, 49-50(1916).—Descriptions, with 9 cuts. J. H. MOORE.

Vacuum drier for substances which can be shoveled (grain, etc.). J. E. BRAUER-TUCHORZE. Hanover. *Chem. App.* 3, 50-1(1916).—General remarks, with description and 1 cut of the Paszburg drier (capacity 55 tons per 24 hrs.). J. H. M.

Illuminating gas retort for school instruction. RICHARD SCHULZE. *Chem. App.* 3, 54(1916).—To illustrate the production of illuminating gas, an Fe pipe about 20 cm. long and 2.5 cm. diam. is closed with caps and filled with small lumps of coal. Near 1 end is an exit pipe connected with suitable scrubbers for purifying the gas. The retort is heated with Bunsen burners. J. H. MOORE.

A universal switch for thermoelement work and other potential measurements. W. P. WHITE. Geophys. Lab., Washington. *Am. J. Sci.* 41, 307-16(1916).—This switch is intended to favor rapidity and completeness in measuring. It enables different thermoelements (or other sources of unknown e. m. f.) to be quickly connected for reading in a variety of combinations with other app., such as potentiometers. Contact is made between thin strips of Cu, which is thermoelectrically one of the best forms of contact known and permits the use of very simple mechanical arrangements. The mechanical arrangement is such that for each combination of app. used the connections are made by pressing an appropriate button; the combinations can be changed by rotating the buttons. The switch is also very easy to overhaul and to construct. W. P. WHITE.

A new form of optical pyrometer. ANON. *Iron Age* 97, 779-80(1916).—This instrument aims to improve, without greatly altering, the usual practice, which is to judge temp. by color. The light from the object measured is compared directly.

with an illuminated color scale. The whole instrument is about the size of a pocket flashlight, and gives results "to 1 or 2%." W. P. WHITE.

Apparatus for producing ultraviolet radiation. W. S. ANDREWS. *Gen. Elec. Rev.* 19, 317-9(1916).—The high tension disruptive spark between Fe terminals is very rich in ultraviolet radiation covering about 80% of that part of the spectrum which is useful for producing fluorescent effects. Compared to other metals tried, Fe shows a more uniform distribution throughout the entire range. Accordingly Fe electrodes have been adopted in the new app. described. The complete outfit comprizes a small transformer that steps up 60-cycle 110-volt a. c. to about 4000 v.; a condenser; an adjustable spark gap. The app. can safely be connected to any a. c. lighting circuit since only 250 to 300 watts are consumed. A number of interesting expts. with willemite and other salts are briefly described. Diagram of connections is shown. C. G. F.

New apparatus. F. MEYER. *Chem. Ind.* 39, 20-1(1916).—A description with cuts of the Bihn-Jones automatic air device for raising or handling large quantities of liquids, and the Wiegand chain screen doors. (Cf. *Met. Chem. Eng.* 13, 875-7(1915).)

F. W. SMITHER.

Cleaning and sterilizing apparatus (BARLADEAN) 17.

Purifying air or gases. H. GRIEN. *Ger.*, 286,221, July 28, 1912. The air or gas is forced or aspirated through the concentric downwardly directed and enlarged supply tube 1, into the washing liquid, passing thence upwards through the space formed by the concentric jacket 2, which does not dip so deeply into the liquid as does tube 1, and which is perforated near the closed top surface, around the sides. The air or gas passes through the perforations, whereby the gas bubbles are broken so that the impure gas contained therein will be purified upon passing again through the washing liquid under the lower edge of jacket 3 which surrounds the system concentrically and dips still less into the washing liquid. After passing under the edge of jacket 3, the gas or air rises and passes out through the exit tube 4.

During the operation the liquid assumes the uneven surface as shown by dotted lines. The level n of the liquid is maintained const. by the overflow 5.

Diffusion apparatus for detecting gas in air. H. R. WEBSTER. U. S., 1,174,370, Mar. 7. The app. is especially designed to detect CH_4 in mines. The vessel a is formed of porous material surrounded by a layer of cotton fibers t and a layer of moisture-absorbing material u which may be KOH or CaCl_2 to protect the porous receptacle from clogging by H_2O or coal dust when the outer cover w is removed. The KOH or CaCl_2 also serve to prevent interference of CO_2 with the operation of the app. When in use the cover w is removed and the app., previously filled with pure air, is exposed to the atm. to be tested. CH_4 by diffusion causes increase of pressure within the chamber a and the diaphragm b actuates an indicating hand on the outside of the app.

Gas-analyzing apparatus. G. A. BURRELL. U.S., 1,176,199, Mar. 21. (Dedicated for free use by any person in the U. S.) To determine the amt. of CH_4 , CO , gasoline vapor or other combustible gas or vapor in air, the app. is filled with H_2O to the levels S and Q in the tubes C and A , by removal of the plug P , which is then replaced. By gaseous pressure or blowing in the app. at R the level of H_2O is raised to cause slight overflow into the cup K . A sample is then drawn in at V by allowing escape of air at R and equalizing level of H_2O in the tubes. A filament F is elec. heated by current supplied to terminals M and N to effect combustion of the combustible constituents present and after cooling the diminution in volume indicates the approx. compn. of the sample.

Quantitative analysis of gas mixtures with known constituents. SIEMENS & HALSKE AKT.-GES. Aust., 70,788, Dec. 27, 1915. In the quant. analysis of gas mixts. with known constituents, with the employment of a standard gas for comparison, according to 69,801, the speed of rotation of the centrifugal app., which causes the pressure difference necessary in detg. the compn. of the gas, is automatically regulated by the position of a manometer which is connected with the centrifuge for the standard gas, in order to render independent of temp. and pressure changes the reading of that manometer which is connected with the centrifugal app. for the gas under examn.

Quantitative analysis of gas mixtures with known constituents. SIEMENS & HALSKE AKT.-GES. Aust., 70,787, Dec. 27, 1915. In the quantitative analysis of gas mixts. with known constituents, according to 69,801, with the employment of a standard gas which is set in rotation at the same rate, whereby both samples of gas are kept at the same temp. and under the same pressure, the pressure differences caused by both gases are registered on the same indicator, which shows the proportion of the pressure difference.

Vapor burner. J. FELDMEYER. Ger., 286,179, July 4, 1911. The vaporizer is mounted on the cap plate.

Straight tubular burner for gas-air mixture. JUNKER & RUH. Ger., 286,263, May 8, 1914. The burner tube is revoluble and movable longitudinally, so that the regulation of the proportions of gas and air, as also the variation of the direction and position of the flames may be controlled by the tube itself.

Drying drums. C. KOCHEN. Ger., 285,817, Apr. 23, 1914. Construction whereby the caking and burning of the material on the charging chute is prevented.

Vacuum apparatus. W. GAERDE. Ger., 286,404, Sept. 25, 1913. The connection with the vacuum chamber is closed by a diffusion diaphragm. A current of steam is conducted past the side of the diaphragm towards the vessel, while upon the vacuum side a condensation or absorption app. takes up the diffused steam.

Furnaces. F. ORTH. Brit., 23,243, Nov. 28, 1914. In reversible chequer-work regenerators, in order to prevent the upper courses of the chequer-work from becoming clogged by the fusion of dust or the like, the speed of the gases is reduced on entering the regenerator, and the gases are passed through large passages of a primary heat-absorbing structure and then through distributing channels of large area before entering the smaller passages in a secondary structure of ordinary chequer-work.

Apparatus for washing filter masses. UNIONWERKE AKT.-GES. MASCHINENFABRIKEN. Aust., 70,785, Dec. 27, 1915. The app. is constructed in such manner that the

greater part of the fouled water is drawn off before the filter mass enters the washing device.

Acetylene generator. J. G. HARSTER. Ger., 286,576, May 24, 1914.

Automatic acetylene generator. W. J. JACKSON. Brit., 23,191, Nov. 27, 1914.

Acetylene generator. J. W. and E. H. SMITH. U. S., 1,175,568, Mar. 14.

2. GENERAL AND PHYSICAL CHEMISTRY.

WILLIAM D. HARKINS and E. B. MILLARD.

The scattering of X-rays and atomic structure. C. G. BARKLA AND JANETTE G. DUNLOP. Univ. Edinburgh. *Phil. Mag.* 31, 222-32(1916).—The scattering of X-rays of very short wave-lengths by equal masses of various substances increases only little with the at. wt. of the scatterer. With greater wave-lengths increase of at. wt. brings a more marked scattering and for long wave-lengths the scattering by heavy metals is considerable. The mass absorption coeff. can be const. only if each electron acts independently of all others; this is the case only for short wave-lengths but there the number of electrons indicated is about half the at. wt. The effect of heavier atoms on long wave-lengths is due to scattering by groups of electrons. G. L. WENDT.

Radiations from atoms and electrons. J. J. THOMSON. *Engineering* 101, 259-60, 282-4(1916).—Lecture. The regularity of interference bands is no indication of corresponding regularity in the vibration of the luminous body producing the light; it depends entirely on certain peculiarities of the instruments used or of the medium passed through by the light in the interval between its emission and its reception on the screen. If a wave passes through a homogeneous medium, its character and length remain unchanged, *e. g.*, the "crack" of a whip is propagated through air without any tendency toward prolongation. If this same sound be reflected from a flight of steps it corresponds to a long musical note of definite pitch because the foot of the disturbance on reaching the nearest step was reflected back, but the rest of the impulse passes on to the rizer of the next step, etc. This illustrates the way in which light reflected from a grating depends entirely on the grating and not at all on the character of the original light. The formation of several types of wave from a single disturbance on water is similar to the action of a prism on light. The expts. of Michelsen on interference of Hg light showed that a Hg atom sustained vibrations with such persistency that after over 500,000 vibrations perfect interference was still possible. Apparently the necessary precision of phase is produced by the light itself, and the light is not produced by a single vibrating atom, but by a considerable number of luminous centers forced into phase by their mutual interaction. The stream of green light in passing Hg atoms excites them to radiate in phase with itself. This phase is forced on the atoms, and as one ceases to radiate another begins, and the phase in which it starts is fixed by the stream of light in which it lies. The regularity of Michelsen's wave train is due to the medium through which the light passes, not to the source of light. Several mechanical models were used to show that vibrations could be transmitted from one system to another not of the same period. If light from a salted burner falls on Na vapor, there is an intense reflection, and back of this reflecting layer there is a region of faint glow. If the wave-length is properly chosen, the reflection is as complete as from white paper. The expts. of R. W. Wood were used to illustrate the fact that as long as the vapor is in phase with the incident light there is no absorption, and that this occurs only when there are irregularities in the substance through which the light passes.

E. B. MILLARD.

Magnetic rotary dispersion in relation to the electron theory. I. The determination of dispersal periods. S. S. RICHARDSON. Univ. Liverpool. *Phil. Mag.* 31, 232-56(1916).—Measurements of the magnetic rotary dispersion in the ultra-violet by H_2O , C_6H_6 , *m*-xylene, and $\text{C}_{10}\text{H}_7\text{Br}$ are applied to a new formula for calcg. dispersal periods. G. L. WENDT.

Determination of the work function when an electron escapes from the surface of a hot body. HORACE H. LESTER. Princeton Univ. *Phil. Mag.* 31, 197-221(1916).—Measurements of the adverse potential difference against which an electron escapes from a hot wire were made for filaments of C, Mo, Ta and W. The values are identical with those for Richardson's const. b , which represents the work done by an escaping electron, and both are similarly affected by traces of active gases. Intrinsic potential differences do not exist, but the observed contact effects are due to ionized surface films formed by the active gases and having a potential which opposes the escape of electrons and is independent of the applied field. A new method for measuring the temp. of the filaments is suggested, making use of Richardson's equation. G. L. WENDT.

Relative deflections of the positive and of the negative ions as compared with those of the electron. CHAS. T. KNIPP. Univ. Illinois. *Science* 43, 393-4(1916).—Photographs are reproduced showing on a single plate the paths of the simultaneous electrostatic and magnetic deflections of both the large ions (positive and negative) and the electrons streaming from the cathode in an electric discharge tube. The electrons are retained within the field by the use of a low magnetic field. G. L. WENDT.

Free electrons in gases. E. M. WELLISCH. Univ. Sydney. *Phil. Mag.* 31, 186-9(1916).—Free electrons have now been observed in air at 8 cm. pressure, in H at atm. pressure, and in CO and CO_2 at intermediate pressures. Petroleum vapor contains only free electrons and no negative ions. At atm. pressure a trace of O in the H removes the free electrons but at lower pressures the effect decreases rapidly. This is ascribed to the necessity for a critical velocity of collision below which a free electron cannot effect a permanent union with the molecule concerned. G. L. WENDT.

Properties of mechanically pulverized mercury droplets and the charge of the electron. A. SCHIDLOF AND A. KARPOWICZ. *Arch. sci. phys. nat.* 41, 125-48(1916); cf. *C. A.* 10, 550.—An app. similar to that formerly used, based on the Millikan app., was employed to study the rise and fall of small charged drops of Hg between the plates of a condenser. The time of fall of a drop increases continually and indefinitely, on account of evapn. of Hg from the surface of these droplets. This takes place in an atm. which is satd. with Hg vapor, even when large drops are on the lower plate of the condenser. The drops used by Millikan were said to be volatile as well. Closely agreeing results were obtained in atms. of air and N. The charge of the electron is $e = 4.818 \times 10^{-10}$ e. s. u., $\pm 0.015 \times 10^{-10}$, in good agreement with Millikan's value, and in fair agreement with the earlier work with oil drops. The expts. of Ehrenhaft on the existence of sub-electrons are discussed (*C. A.* 9, 411, 1000). E.'s droplets could not have had the same chem. compn. as those in the present expts. They did not have the compn. and spherical shape E. assumed for them, and were of poorly-defined character. The coeff. of correction for the Stokes-Cunningham law for small Hg spheres has the same value as that found for slightly larger drops of olive oil, $K = 8.29 \times 10^{-6}$. E. B. MILLARD.

Van der Waals' equation. W. V. METCALF. *J. Phys. Chem.* 20, 177-87(1916); cf. *C. A.* 10, 416.—The equation is again written in the form $p + a/v^2 = RT/(v - b)$, with p the external pressure, $p_2 (= a/v^2)$ the "cohesive pressure," and $p_3 (= RT/(v - b))$ the "elastic" pressure. The paper is a supplement to the previous one pointing out that the "cohesive pressure" varies inversely as the 2nd power of the whole vol., while

the "elastic pressure" varies as the first power of a corrected vol. ($v - b$), and that the cohesive force between the mols. is a function of the av. distance between the center of the mols., while the elastic pressure, depending at any given temp. on the mean free path, varies as some function of the av. distances between the surfaces of the mols. If the mols. are elastic spheres the distance between faces is probably less than half the diam. of the mol. in liquids under ordinary conditions. A math. discussion of these points follows.

E. B. MILLARD.

The kinetics of multirotation in gelatin sols. W. OSTWALD. *Kolloid-Z.* 17, 113-9 (1915).—A mathematical expression for the rotation of gelatin sols., based on the data of Trunkel (*C. A.* 4, 3091) and holding for sols. of less than 1%, temps. between 15° and 25° and rotations between 112° and 245°, is $[\alpha]_D^t = K \cdot t^{0.06}$, $K = 0.687 (100 + 186)$. $K = 9.17 (38 - t)$ in which $[\alpha]_D^t$ is the angle of rotation of the D line at temp. t , t the time after the beginning of the change in rotation, and K a const. which varies with the concn. c and the temp. t as expressed in the last two equations. The importance of the kinetic treatment of colloidal chemical phenomenon is emphasized, but an effort to show a quant. relation between changes in viscosity and in rotation was without success.

H. I. MATTILL.

The influence of capillary active materials on the stability of arsenic trisulfide sols. C. F. VAN DUIN. Utrecht. *Kolloid-Z.* 17, 123-30 (1915).—Pure iso-BuOH was prepd. in order to complete the comparison between the effects of phenol, iso-AmOH and iso-BuOH on the stability of As_2S_3 sols (*C. A.* 8, 603). The effect of these capillary active materials, measured by the concn. of electrolyte necessary to ppt. the As_2S_3 , was directly proportional to their adsorption by blood charcoal. The adsorption isotherms (by charcoal) for phenol, iso-AmOH and iso-BuOH are not proportional to the surface tensions of their sols., for phenol, whose soln. shows the least surface tension, is nearly as strongly adsorbed as iso-AmOH and much more so than iso-BuOH at the low concns. studied. Very carefully purified phenol and iso-AmOH show less adsorption by charcoal than "purified commercial products," the difference being greater than any error of observation; therefore the adsorption of a material is suggested as a test of its purity, after such a difference is once established. Iso-BuOH shows no such difference.

H. I. MATTILL.

The capacity for adsorption of living yeast. P. ROHLAND AND F. HEYDER. *Kolloid-Z.* 17, 139-41 (1915).—In general, inorganic, organic (animal and blood charcoal) and organized (living yeast) colloids show similar capacity for adsorbing dyes, the quantity of dye adsorbed depending on its constitution (*C. A.* 9, 1567), though there are exceptions, notably that the brown dye of the sulfite cellulose industry, much like chlorophyll, is not adsorbed by colloidal silicates and but slightly by living yeast. The constitution of the dye is a deciding factor, but another unknown factor must be considered, for living yeast will not adsorb the vegetable dye, indigo, nor the animal dye, carmin, which are readily adsorbed by inorganic and organic colloids.

H. I. MATTILL.

Adsorption of acids by cellulose. ALAN LEIGHTON. *J. Phys. Chem.* 20, 188-94 (1916).—Cotton was purified with NaOH as in *C. A.* 10, 824. H_2SO_4 , H_3PO_4 , and HCl form no compds. with cellulose, and are adsorbed by it in the above decreasing order. The presence of any one of the acids considerably cuts down the amount of H_2O adsorbed by cotton. Selective adsorption is most marked with HCl, it is less marked with H_2SO_4 and does not occur at all with H_3PO_4 . The sols. used covered a range of concn. up to over 700 g. of acid per l. of soln. for H_2SO_4 and H_3PO_4 , and from 45 to 414 g. of HCl per l. Both volumetric and gravimetric detns. of the acid concn. were carried out, and large differences were observed, because the first method gives only the selective adsorption.

E. B. MILLARD.

Velocity of saponification of fats and oils by potassium hydroxide in different solvents. E. ANDERSON AND H. L. BROWN. *J. Phys. Chem.* 20, 195-213 (1916).—A measured vol. of butter fat, cotton seed, castor, olive or croton oil, or MeOAc was made up to 100 cc. with MeOH, EtOH or C_2H_5OH , brought to the temp. of the thermostat, and mixed with an equal vol. of KOH in the same solvent. Samples were withdrawn and titrated from time to time. All of the saponification reactions were bimol. under the conditions studied. The glycerides are saponified at approx. the same rate. An increase of 1% in the H_2O content of the alc. caused an increase of 4% in the velocity of the reaction. The velocity of saponification of the glycerides in amyl alc. was about twice as great as in EtOH and about 10 times as great in EtOH as in MeOH, all at 15.5° . Between 15 and 25° the temp. coeff. of the reaction const. was 2.36 with castor oil in EtOH. An increase in the concn. of KOH greatly increased the velocity of the reaction, but no definite relation between the velocity and the concn. was found. Increasing the amount of oil causes a decrease in the velocity of the reaction in amyl alc., but increases the velocity in EtOH and MeOH. E. B. MILLARD.

Mechanism of reactions in aqua regia. E. BRINER. *Compt. rend.* 162, 387-9 (1916).—B. has examd. a monovariant system of phases with the 2 components, HCl and $HN\cdot O_3$, and shows that the reaction producing NOCl, Cl_2 , and H_2O is reversible. L. H. CHERNOFF.

Correction of about $1/100$ in freezing-point determinations in diluted aqueous solutions at one degree undercooling. M. G. DEKHUYZEN. *Chem. Weekblad* 12, 24-8 (1915).—D. emphasizes the importance of the above correction which should be detd. for each app. separately. The correction is necessary on account of the increase in concn. due to the formation of ice. J. T. FLOHIL.

Molecular volumes of the hyponitrites of the alkali metals and metals of the alkaline earths. PRAFULLA C. RAY AND RAJENDRALAL DE. *J. Chem. Soc.* 109, 122-31 (1916); cf. *C. A.* 7, 3 903.— $Hg_2N_2O_2$ was pptd. from $HgNO_3$ by an alkaline earth hyponitrite, avoiding an excess of $HgNO_3$, since the hyponitrite is sol. in excess and ppts. as a yellow substance on diln. Difficulty in dehydrating the Ca salt was due to a trace of $CaCl_2$ which was supposed to change the cryst. into the amorphous CaN_2O_2 . Detns. of d. were made with a pycnometer and xylene, as follows: $Na_2N_2O_2$ 2.466 at room temp., $Ag_2N_2O_2$ 5.75, $Hg_2N_2O_2$ 7.33, CaN_2O_2 2.527, SrN_2O_2 2.683, BaN_2O_2 3.891. For the first 3 salts the difference in mol. vol. between nitrite and hyponitrite is much greater than between the corresponding nitrite and nitrate. Sr has an atomic vol. between the values for Ca and Ba, but the nitrite has a larger mol. vol. than either that of Ca or Ba. Expts. have been made on the mol. vols. of some of the hydrates of these salts and vols. calcd. for the crystal H_2O . The vol. occupied by 4 mols of H_2O in the Ca salt is the same as that of the 5 mols. of H_2O in the Sr salt. No const. mol. vol. for crystal water is obtained, and the values in general do not agree with those of Thorpe (1880).. E. B. MILLARD.

Thermometer testing. (Temperature scale.) E. WARBURG. Charlottenburg. *Verh. deut. physik. Ges.* 18, 1-3 (1916); *Ber.* 49, 474-6 (1916).—Beginning with Apr. 1, 1916, the Physikalisch-Technische Reichsanstalt has adopted the following temp. scale: (1) Between the m. p. of Hg and the b. p. of S the scale is detd. by a Pt resistance thermometer, using the equation of the second order; $R = R_0(1 + at - bt^2)$. The consts. are detd. at 0° , 100° , and the b. p. of S, which is detd. by $444.55 + 0.0908(p - 760) - 0.000047(p - 760)^2$. The Pt must be of such purity that R_{100}/R_0 is greater than 1.388 and δR less than 1.52 where $\delta = b \cdot 10^4/(a - b \cdot 10^4)$. The following fixed points have been detd.: Melting or freezing point of Hg -38.89 , of Sn 231.84 , of Cd 321.07 , of Zn 419.4 , the transformation point of Na_2SO_4 32.38 ; the b. p. of $C_{10}H_8$ 217.96 .

+ 0.058($p - 760$), of Ph_3CO 305.9 + 0.063($p - 760$). This scale agrees with the international H scale between these limits within the limits of error. (2) Below the m. p. of Hg the scale of Henning (*C. A.* 7, 2892; 8, 1230) is used. As fixed points the b. p. of $\text{CO}_2 = -78.5 + 0.01595(p - 760) - 0.000011(p - 760)^2$, and of H = $-183. + 0.01238(p - 760) - 0.0000079(p - 760)^2$. (3) Above the b. p. of S the following fixed points are used: M. p. of Sb 630°, Ag 960.5°, Au 1063, Cu 1083, Pd 1557, Pt 1764. For interpolation between these points a thermocouple, Pt-PtRh 10%, is used. The equation is one of the third degree whose constants are detd. by the m. p. of Cd, Sb, Au and Pd. Within the limits of error this agrees with a radiation pyrometer scale in which $\log e H_1/H_2 = C/\lambda \{1/(273 + t_1) - 1/(273 + t_2)\}$ where t_1 and t_2 are the temps. corresponding to the brightness H_1 and H_2 of a black body for wave length λ , and $c = 14300$. F. A. HARVEY.

Location of the thermal energy of solids. A. H. COMPTON. *Phys. Rev.* 7, 349-54 (1916).—An explanation of the sp. ht. according to the quantum hypothesis implies that the heat energy of a solid lies in its elastic vibrations, while according to C.'s agglomeration hypothesis this energy lies in the vibrations of the individual atoms. A previous study of thermal cond. has shown that the distance through which an atomic collision is transmitted is in a crystal many times the distance between neighboring atoms, but is in amorphous substances not many times the atomic distances. The max. wave-length of elastic vibrations which can possess thermal energy appears to be greater for crystalline than for amorphous substances, which is shown to mean that if it is the elastic vibrations which possess the heat energy, the sp. heat of amorphous substances should be comparatively less at low temps. than that of cryst. substances. The fact that expt. shows no such difference indicates that vibrations of period greater than that of the individual atoms probably play no important part in the sp. heat, though the evidence is not conclusive. E. B. MILLARD.

Characteristics of tungsten filaments as functions of temperature. IRVING LANGMUIR. *Phys. Rev.* 7, 302-30 (1916).—A theoretical discussion of the various functions that may be used to estimate the temp. of W filaments. Exptl. data have been taken on the volt-amp.-candlepower characteristics of W filaments as functions of the temp. and the diam. of the filament, and these have been tabulated with derived functions such as watts, ohms, and watts per candle, over the temp. range from the m. p. of W to room temp. All data are corrected for the cooling effect of the leads. Data are also given for the sp. resistance of W and its total emissivity (black body taken as unit). Foote's formula for total emissivity of metals gives accurate results up to 500 or 600° K., but above 1200° K. the results are much too low. The intrinsic brilliancy of a black body as a function of the temp. has been calcd. in terms of the mechanical equiv. of light from Nutting's visibility data by means of the Planck equation. By comparing these results with the exptl. detd. brilliancies of W and correcting for the known emissivity of W the mechanical equiv. of light was found to be 0.00121 watts per lumen. This agrees with the Ives value 0.00125 calcd. from Nernst's data but differs from the Ives and Kingsbury value 0.00159 directly detd. The color of the light from a W filament is distinctly bluer than from a black body at the same temp., and corresponds to that from a black body at 40 to 80° higher temp. An equation for the thermal expansion of W in terms of its length at 300° K. and the first 2 powers of T , has been derived which represents the actual results to within 2 or 3%. E. B. MILLARD.

Study of the hydrogen electrode, of the calomel electrode, and of contact potential. V. W. F. CLARKE, C. N. MYERS AND S. F. ACREE. *J. Phys. Chem.* 20, 243-65 (1916).—To the app. of Loomis and Acree (*C. A.* 6, 823) as modified by Myers (*C. A.* 8, 1378) a new heating device was added, and another form of calomel battery was devised which could be easily cleaned and filled. The 0.1 N KCl-HgCl-Hg system is a const.,

stable system reproducible to 0.01 millivolt. The H electrode is a system which is extremely sensitive to small amounts of impurities and suited to the detn. of small H^+ ion concns. $Hg-HgCl-0.1 N KCl-0.1 N HCl-Pt-H_2$ is an accurate and const. element which gives one of the best intercomparisons that can be obtained. The 0.1 N $HCl-HgCl-Hg$ system is rather unsatisfactory for long periods of time, due to the formation of Hg and $HgCl_2$. An accuracy of 0.01 millivolt may be obtained with these electrodes if the materials are carefully purified.

E. B. MILLARD.

Factors affecting the electromotive force of binary solid alloys. D. F. SMITH AND N. T. GORDON. *J. Phys. Chem.* 20, 228-42(1916).—Zn-Cu alloys were prepd. by melting Zn under borax and adding Cu in the required amt. The specimens were annealed at 700-750°. The expts. reported are preliminary in character. Detns. of the e. m. f. of the alloys were made with Hg_2SO_4 and normal calomel electrodes on polished pieces cut from the melts, and these indicated that brasses could be prepd. which would give reproducible results if the specimens were subjected to no mechanical treatment from one expt. to the next and which would show gradual progressive changes of potential. A very marked but unexplained influence is exerted by surface treatment, producing with a given alloy and electrolyte "drifts" even the direction of which cannot be foreseen. Expts. on the influence of grinding, sawing and polishing are in progress.

E. B. MILLARD.

Electromotive forces. W. D. BANCROFT. *Trans. Am. Electrochem. Soc.* 28, 357-67(1915).—Nernst's original formulation of the e. m. f. of a cell in terms of the soln. pressure of the electrodes and the osmotic pressure of the ions in soln. is not readily applicable to all classes of cells. A more general statement of the e. m. f. is obtained by combining van't Hoff's formula for the reaction isotherm $A = RT \ln K \Sigma p_1 / \Sigma p_2$ with the expression for electrical energy $A = nFE$ to give the working equation $E = (RT/nF) \ln K \Sigma p_1 / \Sigma p_2$ in which Σp_1 refers to the substances which are consumed during the reaction and Σp_2 to the substances which are formed. It is shown how this formula may be applied to 5 classes of cells which are ordinarily treated in different ways: cells with reversible metallic electrodes, amalgam cells, gas cells, oxidation and reduction cells, chemical affinity cells.

E. SCHRAMM.

Direct photoelectric determination of Planck's "h." R. A. MILLIKAN. *Phys. Rev.* 7, 355-88(1916).—Einstein's photoelec. equation has been subjected to very searching tests and it appears in every case to predict exactly the observed results. The value of "h" has been detd. with a precision of about 0.5% and has the value 6.57×10^{-27} .

E. B. MILLARD.

Light sensitiveness of cuprous oxide. A. H. PFUND. *Phys. Rev.* 7, 289-301 (1916); see *C. A.* 10, 418.

E. B. MILLARD.

The absorptive power of luminous gases. F. SALZMANN. *Sitzb. Akad. Wiss., Wien, Abt. IIa* 123, 2071-84(1914); *Beiblätter Ann. Physik* 39, 518(1915).—The specific absorptive power of the luminous vapors of Li, Na, Sr and Tl was measured by a spectrophotometer, using an elliptical flame with an axial ratio of 2:1, and coloring the flame by spray from solns. of differing concns. Li and Na show 2 minima which are attributed to the varying intensity of the 2 red lines of Li and by the broadening of the lines at high concns. in both cases.

G. L. WENDT.

Energy changes in photochemical processes in gases. VI. Photolysis of hydrobromic acid. E. WARBURG. *Sitzb. kgl. preuss. Akad. Wiss.* 1916, 314-29; cf. *C. A.* 9, 883; 10, 546.—As a further test of the Einstein law of photochem. equivalents the photolysis of HBr has been detd. by passing a stream of H or N through satd. HBr at 0° and, after drying at -77°, conducting it through a decomposition cell on which Zn-spark radiation was falling, and finally through KI soln. Traces of O were removed

from the H or N by passing over hot Cu. The quantity of Br freed per g. cal. of radiation of a definite wave length and the partial pressure of the HBr in the gas mixt. were detd. for $\lambda = 0.209\mu$ and $\lambda = 0.253\mu$ for several concns. of HBr with an accuracy of a few %. There was a slight deviation from the Ångström law, i. e., a slight increase in the mol. absorption with increasing partial pressure of HBr. The sp. photochem. action was independent of the velocity of the gas stream, of the nature of the admixed gas, and has the value 1.53×10^{-8} mol. Br/g.-cal. for $\lambda = 0.209$. The mol. absorption for $\lambda = 0.253$ is about 7% greater than for 0.209, the av. value of the sp. photochem. action being 1.79×10^{-8} . As has been found before, the Einstein law does not hold for photolysis.

E. B. MILLARD.

The reflecting power of metals in the ultraviolet region of the spectrum. E. O. HULBURT. Johns Hopkins Univ. *Astrophys. J.* 42, 205-30(1915).—The reflecting power was measured for a fixed angle of incidence, viz., 18° , throughout the region 3800 to 1800 Å. Curves of reflecting power are given for the following substances: Au, C, Pt, Mg, Ni, Te, Cu, Sb, Ag, Cr, stellite, Pb, Se, steel, Pd, Si, Al, carborundum, Cd, Bi, W, Co, magnalium, speculum, Zn, Mo, Ta. The curves show 2 general characteristics; in the region studied the reflecting power decreases as the wave-length decreases, and the reflecting power is never zero. Several of the curves show a marked decrease in reflecting power beginning about 2000 Å. Cu, Cr, Ni, Mo, and cathodic Si all show a shallow minimum about 2400 Å. Ag differs from the others in that it has a decided minimum at 3100 Å., the reflecting power falling to about 5%, then rising to 32% at 2400 Å. Si gives the max. reflection, 76%, at 3000 Å., decreasing to 62% at 1870 Å. Pt and Ni are most serviceable as mirrors in this region. They reflect about 30% at 2000 Å. and are resistant to chem. action. The reflecting power for wave-lengths shorter than 3000 Å. is rarely above 50%.

The application of the activation theory to oxidation phenomena. H. J. PRINS. *Chem. Weekblad* 12, 38-48(1915).—A lecture dealing with: the action of O, the action of O in the presence of catalysts and action of O in O compounds. J. T. FLOHL.

Fluorescing sodium uranyl phosphate. H. L. HOWES AND D. T. WILBER. *Phys. Rev.* 7, 394-6(1916).—Mixts. of $\text{H}_2\text{UO}_4\text{PO}_4 \cdot 3.5\text{H}_2\text{O}$ and Na_2HPO_4 in the mol. ratio 1:1, 2:1 and 4:1 at -180° gave exactly similar spectra when excited by the C arc. Other specimens were prepd. contg. more H_2PO_4 , and in these the strongest line series were suppressed and the dimmer lines were merged into broad bands. The spectra of the mixts. containing no H_2PO_4 consisted of recurring groups of bands. The interval on any one of these line series has a value lying between 80 and 81 units, which is the shortest interval yet observed in the study of the fluorescence spectra of uranyl salts. With either H_2PO_4 or HNO_3 as a solvent the solid at low temps. has a vitreous appearance, perhaps because the acid is still dissolving the phosphate even at the temp. of -180° . If the acid were crystalline presumably the broad bands which appear would not be present. From the expts. with glassy and cryst. solids it appeared that cryst. form was a necessity if a resolved spectrum was to be obtained.

E. B. MILLARD.

The crystallization of diphenyl ether. C. DAUVERNE. *Compt. rend.* 162, 385-7 (1916).—Through the microscope, D. observed that when a crystal of Ph_2O is introduced into liquid Ph_2O at 20° there was at first a rush of liquid towards the crystal, producing a whirling motion. Another undulatory motion was observed towards the plane sides of the crystal. These waves cause the ridges and growth of crystals, and also their cicatrization.

L. H. CHERNOFF.

The thermionic current generated in an electric lamp at incandescence. ALFREDO GRANDONE. *Rend. accad. sci. fis. et mat. Napoli* [3] 21, 165-72(1915).—In studying elec. resistance from the electron point of view G. made some observations on the nature

of the thermionic current generated by an incandescent lamp with a C filament and one with a W filament. From the numerical results it was calcd. that a 16 c. p. C filament lamp at 110 v. emits 0.32×10^{10} electrons per unit of surface per unit of time.

3. RADIOACTIVITY.

WILLIAM H. ROSS.

Remarks on the production of radium by the Bureau of Mines. CHARLES H. VIOL. Standard Chem. Co., Pittsburgh. *J. Ind. Eng. Chem.* 8, 284-6(1916).—Polemical with respect to the conclusions reached by Parsons, *et al.* (*C. A.* 10, 424) on the cost of extg. Ra from carnotite ores by the method devised by the Bureau of Mines.

W. H. ROSS.

The atomic weight of radium emanation. S. C. LIND. Bur. of Mines, Denver. *Science* 43, 464-5(1916).—In the International Atomic Weights Table for 1916, the Commission has adopted for Ra the value of 226.0 obtained by Hönigschmid in 1911 (*C. A.* 7, 19). The at. wt. of Ra Em, however, has been retained at its former value of 222.4 instead of substituting 222.0 which would conform with the new value for Ra. The exptl. value obtained by Gray and Ramsay was 223 (*C. A.* 5, 1869), and the value of 222.4 was simply chosen on purely genetic grounds in accord with the then accepted value for Ra of 226.4. L. now points out that since the value for Ra Em of 222.4 was thus chosen in recognition of the principle of genetic relationship among the radioelements, it would now appear requisite that the at. wt. of Ra Em should be changed automatically to accord with that of Ra, and that there is no sufficient reason to retain the old value of Ra Em in the new Atomic Weights Table. W. H. ROSS.

The laws of the passage of alpha rays through air. L. FLAMM. *Elster-Geitel Festschrift* 1915, 601-22; *Beiblätter Ann. Physik* 39, 752(1915).—A review.

G. L. WENDT.

The ionization-current curve with alpha rays. A. LIEBERT. *Vierteljschr. natur. Ges., Zürich* 59, 117-44; *Beiblätter Ann. Physik* 39, 120-1(1915).—The curves obtained may be erroneous unless contact potentials are avoided. The direction of the current may also be a factor in case the electrodes are unsymmetrical. A magnetic field can introduce an effect on the current due to ionization by collision, and this is dependent on the gas pressure, the potential applied, the strength of the magnetic field and the form of the electrodes.

G. L. WENDT.

Radium, uranium and vanadium. FRANK L. HESS. U. S. Geol. Survey, *Mineral Resources of U. S., 1914*, Pt. I, 943-6 (Separate 25, published Feb. 26, 1916).

E. J. C.

A tungsten target for X-ray tubes. J. H. GARDINER. *Nature* 97, 67-8(1916); cf. *J. Röntgen Soc.* 6, 83-97(1910).—Attention is directed to the exceptional properties of metallic W which makes it particularly suited for use in anticathodes for X-ray tubes. It is very tough, does not readily disintegrate by cathode discharge, and has a very high fusing point of about 3000°. In this way anticathodes made of W offer an advantage over those made of Ni covered with Pt foil, for under a heavy discharge the latter alloys with the Ni backing and is thus soon destroyed.

W. H. ROSS.

A difference between the action of light and of X-rays on the photographic plate (SALOMONSON) 5.

4. ELECTROCHEMISTRY.

COLIN G. FINK.

Electrochemical industries in Russia. H. G. *Chem. Ind.* 38, 532-3(1915).—A brief review. F. W. SMITHER.

Service requirements of the electric arc furnace. H. HOLLIS. *Elec. World* 67, 766(1916).—Generation, transmission and transformation of the power is discussed. The characteristics of a furnace load and its regulation are considered. As to the desirability of the elec. furnace load for central stations, H. looks upon it as a very favorable business for a plant of moderate capacity. W. E. RUDER.

Operating characteristics of a small electric furnace. J. C. MATHIEU. *Elec. World* 67, 262(1916).—Performance curves are given of a one-ton single-phase arc furnace (apparently of the Snyder type) for melting steel scrap. The av. load was 380 kw., input per ton of steel 660 kw.-hr., av. power-factor slightly over 55%. Current, power, and power-factor readings were fairly constant except when cold scrap or flux was added. F. A. STRAUSS.

Addition agents in the electrodeposition of silver from silver nitrate solutions. F. C. MATHERS AND J. R. KUEBLER. *Indiana Univ. Trans. Am. Electrochem. Soc.* 29, 131-43(1916).—The aim of the investigation was to discover a method of depositing solid, smooth and adherent Ag cathodes. Additions of glue, peptone, gum arabic, pyrogallol and tannin only partially restrained the characteristic, loosely adherent, cryst. structure of the Ag and did not produce smooth deposits. Additions of HPO_4 increased the hardness and non-cryst. character of the deposit, but the bath soon deteriorated. Additions of H_2PO_4 and HNO_3 , 2% of the nitrates of NH_4 , Na, K, Ba, Sr, Ca, Mg, $\text{H}_2\text{C}_4\text{O}_4$ and HNO_3 , succinic acid, lactic acid, picric acid, tannic acid and citric acid produced no beneficial results. From a bath containing 3% each of AgNO_3 , HNO_3 and tartaric acid, it was found that a smooth, hard and entirely adherent deposit of Ag could be obtained. By the simultaneous addition of 0.01% of glue every 12 hrs., it was found that the amt. of tartaric acid could be reduced to 0.4%, and that the deposit obtained was much smoother and of a darker, more shiny color. The addition of 2% of $\text{Fe}(\text{NO}_3)_3$ to the above bath renders the deposit much smoother, darker, and more shiny; but deposits so obtained contain 0.086% of Fe. The best results were obtained when the above bath was only gently stirred, by a slow current of air bubbles, and a c. d. of 7.4 amp. per sq. ft. (0.8 amp. per sq. dcm.) employed. The total wt. of tartaric acid used up is 0.005 of the wt. of Ag refined. The consumption of tartaric acid and glue corresponds to a max. cost of 0.23 cent per lb. of refined Ag. As the deposit of Ag formed in this way is brittle, it is of no value in electroplating.

H. JERMAIN CREIGHTON.

The disintegration product of carbon anodes in acids. B. L. VANZETTI. *Ann. r. ist. Veneto* 72, II, 445-50; cf. *C. A.* 8, 281.—I. When an elec. current is passed between carbon electrodes in acid or alk. soln., the anode is attacked with the deposition of a black powder. V. finds that this substance is colloidal in nature and that it gives stable suspensions in pure H_2O or alk. solns. It is a negative colloid, as it is pptd. by acids and migrates to the cathode under the action of an elec. current. II. *Ibid* 1057-71.—Carbon electrodes were purified by heating to a high temp. in a current of Cl. This treatment, however, was not sufficient to remove traces of Fe and Si. The black powder formed at the anode on passing an elec. current between the C electrodes

in acid soln. was treated with dil. KOH soln., filtered, HCl added to the filtrate and the black ppt. which sepd. on acidification washed several times with HCl to remove traces of Fe. The black substance was evapd. at 100° and finally heated to 110° for several hrs. A small quantity of adsorbed Fe and HCl was extremely difficult to remove. By this treatment a friable black mass was obtained which easily formed a colloidal soln. in dil. alkali. Heated *in vacuo* this powder liberated CO and CO₂. After this latter treatment the residue no longer had the property of forming a colloidal soln. in dil. alkali. III. *Ibid* 1065-71.—Detns. were made of the compn. of the gases evolved at anode and cathode in acid soln. during the passage of the elec. current. At the anode, the principal gases evolved were CO₂ and CO with traces of O and H. At the cathode the principal gas was H with some CO₂ and CO. V. concludes that the product formed by the disintegration of the anode adsorbs relatively large quantities of the two principal gases CO and CO₂. On heating the substance *in vacuo* the adsorbed gases are given off. IV. *Ibid* 73, II, 767-74.—Various expts. were made to det. the chemical individuality of the anode substance. The suspension in alk. soln. was treated with dil. HCl and the ppt. thoroughly washed and analyzed. The results agree with the formula proposed by Bartoli and Papasogli—C₁₁H₂O₄. The anode substance was added to concd. KOH soln. and dialyzed until no further trace of KOH could be detected. Part of the suspension was then evapd. in a Pt dish and the K content found to be 17-18%. The neutral soln. of the K salt gave ppts. with the solns. of a number of metallic salts. The salts were analyzed and the calcns. made of the acid equiv. show good agreement. The substances obtained by pptn. with metallic salts however, are amorphous in appearance. V. considers this to furnish reasonable doubt as to the chemical individuality of the anode product.

L. T. FAIRHALL.

Minimizing electrolysis of cable sheaths. ANON. *Elec. World* 67, 769(1916).—The best method to accomplish this end is to improve the return circuits of all grounded systems in the vicinity, minimize the opportunities for stray currents to reach the cable sheaths and provide high conductivity paths for sheath currents where they tend to leave the cable. Methods used by the Edison Co. of Brooklyn to accomplish these ends are described.

W. E. RUDER.

High current transmission with zinc cables. L. LICHTENSTEIN. *Elektrotechn. Z.* 37, 4(1916).—Calcns. are made showing the comparative conditions for the use of Zn in the place of Cu for transmission. Expts. show that Zn does not deteriorate appreciably when very much overloaded. Heating to $200-350^{\circ}$ for short periods did not alter the ductility to a prohibitive point and the surface appearance showed no change until the m. p. was approached.

W. E. RUDER.

A history of the lightning arrester. A. J. WURTS. *Elec. J.* 13, 168(1916).—A detailed illustrated exposition starting with the early types of 1890. W. found that in the spark gap type there were 5 metals, Bi, Sb, Cd, Hg and Zn, which were particularly serviceable on account of their non-arcing property; Hg is the most effective and quick-acting.

C. G. F.

Photometry of gas-filled lamps. G. W. MIDDLEKAUFF AND J. F. SKOGLAND. *Bur. Standards, Sci. Paper* No. 264, 587-604(1916).

C. G. F.

Life testing of incandescent lamps at the Bureau of Standards. G. W. MIDDLEKAUFF, B. MULLIGAN AND J. F. SKOGLAND. *Bur. Standards, Sci. Paper* No. 265, 605-30(1916).

C. G. F.

Candle power measurements of series gas-filled incandescent tungsten lamps. R. C. ROBINSON. *Trans. Illum. Eng. Soc.* 11, 187-91(1916).—For comparing lamps and expressing temps. the watts per spherical c. p. should be used. The horizontal

c. p. readings are very much effected by changes in the design of the mounting of the filament.
C. G. F.

Chemical, electrochemical and metallurgical industries of Scandinavia 18. Characteristics of tungsten filaments as functions of temperature (LANGMUIR) 2. Cellon and cellon varnish 26.

Dry battery cell. V. G. APPLE. U. S., 1,174,798, Mar. 7. Structural features.

Storage battery. J. O. LUTHY. U. S., 1,175,280, Mar. 14. Structural features.

Storage battery electrode. W. MORRISON. U. S., 1,175,370, Mar. 14. Pb electrodes are superficially permeated with a Ti compd. deposited electrically from H_2SO_4 soln., to increase their durability.

Electrolytic apparatus for preparing bleaching liquor from sodium and magnesium chlorides. J. F. WEBB and W. W. WILLIAMS. U. S., 1,175,572, Mar. 14.

Cell for electrolyzing alkali chloride solutions. K. HEINEMANN. U. S., 1,176,551, Mar. 21. A flowing Hg cathode is used and the bottom plate of the cell is provided with obstructions more inclined on the side directed against the flow of Hg than on the other side, to effect a uniform mixing of the amalgam.

Electrolysis of alkali metal chloride solutions. A. E. GIBBS. U. S., 1,176,540-1, Mar. 21. Soln. is fed from the cup 15 (the height of which is adjusted to give the best efficiency of feed at different periods during the life of the cell) and passes through the permeable diaphragm 4 to the cathode 3 upon the projections of which the greater part of the electrolysis takes place. The caustic alkali produced is carried out through holes in the cathode and is washed down by electrolyte overflowing through perforations 13 in the upper portion of the diaphragm. The anodes 9 are C rods. 11 is a gas outlet.

Electrolysis. H. C. JENKINS, H. F. PARTISON and R. WELLESLEY. Brit., 22,867, Nov. 21, 1914. In app. of the "bell" type, as that described in 25,415, 1913 (C. A. 9, 1155), the floor of the cell is made with a ridge beneath each bell and with intermediate depressions at the bottoms of which are grooves communicating with outlets at one side of the cell. The electrodes, generally the cathodes,

which are outside the bells, consist of pairs of vertical plates sepd. by successively wider spaces from the lowest upwards. Liquid products can thus pass between the plates to the groove beneath them, and thence to the outlets, without disturbing the main body of electrolyte. Gases, if evolved, may be collected by a cover.

Electrodeposition of copper. S. C. BABCOCK and E. W. HAGMAIER. U. S., 1,174,466, Mar. 7. In depositing Cu electrolytically from $CuSO_4$ soln., about 0.2% of phenol-sulfonic acid or similar compd. is added to the soln. to accelerate the deposition and obtain a perfect and dense deposit.

Chromium alloy for electrical resistance elements. W. B. DRIVER. U. S., 1,175,724, Mar. 14. An alloy of Cu, Ni and Mn, which may be in about the proportions of 30:50:10, resp., is combined with 2-10% of Cr to increase resistance to oxidation.

Electric resistance furnace. T. F. BAILY and F. T. COPPE. U. S., 1,176,018, Mar. 21. Hollow blocks 6 support the bottom wall 7 of the furnace. Heat is furnished

by granular C or other resistance material, 13 in troughs supplied with current by electrodes 14 and heat rays are deflected to the hearth 10 by both the upper arched roof 24 and the inclined brick walls 16 below the hearth, to conc. the heat upon the latter.

Cyanides and cyanamides; electric furnaces. J. E. BUCHER. Brit., 23,292, Nov. 30, 1914. Modification of the process of 27,713, 1912 (C. A. 8, 1857), for the fixation of N with the aid of a catalyst such as Fe. The materials, *e. g.*, Na_2CO_3 , C and Fe, may be used in the form of small briquets or in a single mass with channels formed in it, or even in the form of powder, and the heating to a temp. below that at which the catalyst fuses is effected by elec. current passed through the material, the material being first sufficiently heated to render it conducting. A suitable furnace is shown.

Cyanides and cyanates; ammonia; electric furnaces. A. R. LINDBLAD. Brit., 22,852, Nov. 21, 1914. Cyanogen compds., such as cyanides and cyanates of alkalis and alk.-earths, are produced by the reaction of N on solid charges in elec. furnaces having one or more shafts or openings for feeding in the charge, and a melting chamber having such a form, *e. g.*, a frustro-conical form, that at one or several places the charge spreads itself to produce inclined surfaces, at which it contacts with the electrodes, which enter the melting chamber at its upper part.

Controlling the load of a diaphragm. ELEKTRO-OSMOSE, AKT.-GES. (GRAF SCHWERIN GES.). Aust., 70,744, Dec. 27, 1915. The extent and character of the adsorptions are varied during the process.

Galvanized tires. COLUMBUS-WERKE G. M. B. H. Ger., 283,399, Dec. 5, 1912. Addition to 281,499. Arrangement of the anode according to the principal patent.

Tungsten. GLÜHFADENFABRIK, AARAU AKT.-GES. Brit., 23,496, Dec. 3, 1914. Pure W is obtained in massive, malleable, and ductile form by fusing the powder completely and then rapidly cooling it. The W is packed in a tube heated elec. in the manner described in 23,495, 1914, and after fusion, the resistances are raised and blasts of cold air from funnels are caused to impinge upon the tube.

Compacting tungsten. J. A. WILLIAMS. U. S., 1,174,646, Mar. 7. Bars of W are formed from the finely divided metal by exhausting the air from a mass of the W and subjecting it *in vacuo* to pressure in a hydraulic press. A very dense metal is obtained by sintering, swaging and heating the compressed bars.

5. PHOTOGRAPHY.

LOUIS DERR.

Physiological aspect of photographic safe light screens. H. HARTRIDGE. Cambridge. *J. Physiol.* 50, 95-100(1915).—A screen made up of red and green components which transmitted a spectrum extending from $\lambda 680$ to $\lambda 530$ while photographically safe gave much better visual effects than did the ordinary orange and red screens. The colors of objects are only slightly modified by this light. Although it contains no blue rays, blue objects appear blue.

J. F. LYMAN.

A difference between the action of light and of X-rays on the photographic plate. L. K. A. W. SALOMONSON. *Proc. Akad. Wetenschappen* 18, 671-82(1916).—In a series of expts. "exposure scales" were obtained in the ordinary way, half the plate being exposed to light, the other half to X-rays, and from measurements of the optical density characteristic curves of the plates were drawn. In each case the curve obtained for X-rays was different from that obtained with light, the latter curve in each case having a greater slope. It is pointed out that in the case of a sensitive medium such as a photographic plate the effect of incident waves will be a function of the absorption coeff. of the film for the waves in question; on this basis an expression for the density, similar to that derived by Hurter and Driffield, is obtained. On this basis it should follow that in the case of the same density, a light-negative should contain less Ag than an X-ray negative, and analyses of a number of films confirmed this conclusion. It should further follow that the slopes of the characteristic curves obtained with light of different wave lengths should be different, a conclusion which is verified by reference to the literature.

Photography on porcelain or on glass 19. Manufacture of "photo" papers 23.

Mixed-color coatings for photographic plates. W. F. BLECKER. U. S., 1,175,224. Mar. 14. Powdered glass or other fusible material of different colors is allowed to fall into the flame of a blast burner by which the particles are melted to spherical form and projected into a settling chamber where particles of different colors are mixed for use in coatings for color-photography plates.

6. INORGANIC CHEMISTRY.

H. I. SCHLESINGER.

The constitution of ultramarine. H. PUCHNER. Weihenstephan. *Kolloid-Z.* 17, 119-23(1915).—In support of the view that the color of ultramarine is due to an adsorption compound and not to a definite chemical individual, P. quotes the results of expts. in which three different types of soil were first impregnated with NaCl then allowed to adsorb water; finally the water-soluble portion was evapd. to dryness and ignited. The soils used were a quartz sand, weakly humus; gypsum containing loam; and humus gypsum lime sand containing fragments of Al_2O_3 and Al silicate and much Ca humate. On igniting the residue from the water soln., the 3rd soil only gave blue residues and that only when the water ext. was not taken from the surface layer of the soil. The blue residue goes gradually to gray on heating and with HCl gives H_2S , and on analysis shows the presence of the lazurite or ultramarine radical in each case, though frequently in only small amt. Replacing NaCl with KCl interferes with the appearance of the blue residue. The concn. of the nitrates on the surface of the soil interferes with the ultramarine formation by preventing the reduction of the S compounds by the humus.

H. I. MATTELL.

The forms of dispersion of metallic silver. R. E. LIESEGANG. Frankfurt. *Kolloid-Z.* 17, 141-5(1915).—The diffusion of $AgNO_3$ and hydroquinone in gelatin gels shows that, within certain concn. ratios, the law of Pringsheim that a ppt. cannot form on both sides of the interface, does not hold. If $AgNO_3$ soln. is allowed to diffuse into gelatin gel containing $FeSO_4$, there results, depending on the concn. of the $FeSO_4$, a flocculent Ag ppt. which appears very black, or by slightly increasing the $FeSO_4$ concn. a banding of green and gray Ag of very complicated structure, or finally by still greater $FeSO_4$ concn. macroscopic glistening leaves. The latter is the densest form, the black

form is the least dense. Similar reaction with FeCl_2 beside forming much AgCl leads to so highly dispersed reduction product of Ag that it may escape observation.

H. I. MATTILL.

Preparation of chloroplatinic acid and chlorides of gold and palladium. ENRIQUE V. ZAPPI. *Anales soc. quim. Argentina* 3, 68-9(1915).—Z. proposes the following method of prepg. H_2PtCl_6 , thus avoiding the necessity of eliminating the last traces of N oxides (present as $\text{PtCl}_4 \cdot 2\text{NOCl}$) which remain when H_2PtCl_6 is prepd. by action of *aqua regia* on Pt. The Pt (as sponge or thin sheets) is placed in a flask and covered with HCl (d. 1.19) and 2.5 cc. of HClO_3 (d. 1.55° Bé.) to each g. of Pt are added in small portions; the nascent Cl produced in this manner attacks the Pt as readily as does *aqua regia*. The action is rapid on Pt sponge even in the cold, but is slower when Pt sheets or wire are used, depending on the area of the surface presented; the temp. should be raised to 50–60° in order to accelerate the reaction. After the reaction is complete the resulting soln. is evapd. to dryness on a H_2O bath, pure H_2PtCl_6 being obtained. This procedure may be extended to the prepn. of chlorides of Au and Pd.

H. S. PAINE.

Preparation of potassium chloroplatinite. ENRIQUE V. ZAPPI. Buenos Aires. *Anales soc. quim. Argentina* 3, 186-8(1915).— K_2PtCl_6 was completely reduced by K oxalate even in the absence of Ir chloride, although the catalytic action of the latter greatly decreases the time required for reduction as stated by Klason; Pt black as a catalyst was as effective as Ir. In order to prepare K_2PtCl_6 free from Ir, PtCl_4 was transformed into K_2PtCl_6 which was washed with hot H_2O and reduced to metallic Pt by boiling with NaOH and glycerol; the Pt thus pptd. was ignited in order to render the Ir insol. and again transformed into PtCl_4 by soln. in *aqua regia* and finally into K_2PtCl_6 , the entire process being twice repeated. The residue of Pt black (free from Ir) was transformed into pure PtCl_4 by soln. in a mixt. of HCl and HClO_3 and finally into K_2PtCl_6 (cf. preceding abstract). K_2PtCl_6 was then prepd. by reduction in the following mixt.: 3.53 g. pure K_2PtCl_6 (prepd. as above), 1.3 g. $\text{K}_2\text{C}_2\text{O}_4$ and 50 g. H_2O . All the K_2PtCl_6 dissolved in 9 hrs., thus completing the reaction, when the mixt. was boiled under a reflux condenser; when 0.1 g. of Pt black was added, there was violent evolution of CO_2 and the reaction was completed in less than 15 mins. under otherwise the same conditions, all the K_2PtCl_6 being dissolved. In order to recover the Pt from the mother liquors resulting from crystn. of K_2PtCl_6 these mother liquors were acidulated with HCl and an excess of KClO_3 was added, thus causing the immediate pptn. of K_2PtCl_6 .

H. S. PAINE.

Reduction of metallic oxides with hydrogen at high pressures. E. NEWBERRY AND J. N. PRING. *Proc. Roy. Soc. London (A)* 92, 276-85(1916).—A wire of W 0.5 mm. in diam. was wound around the magnesia crucible contg. the oxide to be reduced, and the furnace was packed in ignited magnesia and placed in a pressure app. capable of withstanding 150 atm. Commercial H (contg. a small amt. of N as impurity) was pumped in until this pressure was reached, and the oxide was heated to 2500° or below while H_2O vapor was partly removed by Na metal. Cr_2O_3 and MnO_2 were reduced to metals, V_2O_5 to VO , TiO_2 to TiO , Nb_2O_5 to NbO , CeO_2 to Ce_2O_3 and U_3O_8 to UO_2 . Al_2O_3 , MgO , ZrO_2 , Y_2O_3 and ThO_2 were unchanged. The metals obtained, Cr and Mn, are probably purer than those prepd. by any of the methods hitherto used, as was shown by the sharp m. ps. detd. with them. This has not been observed with metals prepd. before.

E. B. MILLARD.

Some reactions of carbonates of calcium, strontium, zinc and magnesium. W. Ö. DE CONINCK. Univ. Montpellier. *Rev. gén. chim.* 19, 27-8(1916).—The action of sol. salts on insol. salts has been studied. Satd. solns. of K_2SO_4 , KHSO_4 , and KNO_3 mixed with

finely pulverized CaCO_3 at room temp. gave in 1-4 weeks in the first 2 expts., CaSO_4 in the last, $\text{Ca}(\text{NO}_3)_2$. Under similar conditions NH_4NO_3 reacted with SrCO_3 ; KNO_3 and NH_4Cl with BaCO_3 ; KHSO_4 with ZnCO_3 and NH_4Cl with MgCO_3 . But KHSO_4 did not react with either SrCO_3 or BaCO_3 . The reactions are hastened at 100° .

L. H. CHERNOFF.

Displacement of acids by hydrogen peroxide. VI. JOACHIM SPERBER. *Schweiz. Anst. Ztg.* 53, 717-20(1915); cf. *C. A.* 8, 1327, 2778.— H_2O_2 ("peraquatic acid") will set free HNO_3 from $\text{Ca}(\text{NO}_3)_2$ and H_2SO_4 from Na_2SO_4 . In presence of pure Cu foil, a brown ppt. is formed of partly hydrated CuO if H_2O_2 is in excess, or green $\text{Cu}(\text{OH})_2$ if H_2O is in excess. Intermediate products are, resp., Na_2O_2 , CaO_2 (peraquates), NaOH , $\text{Ca}(\text{OH})_2$ (aquates), $\text{Cu}(\text{NO}_3)_2$ and CuSO_4 . Also some O is set free. By direct interaction of CuSO_4 and H_2O_2 , the brown ppt. is again formed. H_2O_2 and CuSO_4 in excess, form a green, and with excess of H_2O_2 a brown hydrosol which is gradually pptd. Exceptional ppts. are black CuO , and yellow CuO_2 . The conditions for obtaining these colors were not detd. $\text{Cu}(\text{NO}_3)_2$ gives similar reactions. The pptd. $\text{CuO} \cdot x\text{H}_2\text{O}$ on standing redissolves in the liberated acids.

S. WALDBOTT.

Thallic-thallous compounds. ALFRED BENRATH. *Bonn. Z. anorg. allgem. Chem.* 93, 161-9(1915).—Previous results (*C. A.* 9, 1723) had seemed to indicate the possibility of a specific effect of certain light waves on the equil. in the system TlBr_3 - TlBr - H_2O , and also a specific effect of $\text{H}_2\text{C}_2\text{O}_4$ in the light. To decide the point, the equil. was studied by satg. solns. of various TlBr_3 content with TlBr at boiling, decanting, and then cooling the soln. By slowly heating the cryst. mixture so obtained, the temp. at which the reactions $3\text{TlBr}_3 \cdot \text{TlBr}(\text{yellow}) \rightleftharpoons \text{TlBr}_3 \cdot 3\text{TlBr}(\text{red}) + 2\text{TlBr}$ and $\text{TlBr}_3 \cdot 3\text{TlBr} \rightleftharpoons \text{TlBr}_3 + 3\text{TlBr}$ ceased would be detd. by noting the temps. of disappearance of the yellow or red crystals, resp. These temps., plotted against the initial TlBr_3 content, gave curves tending to intersect at a little above 100° . From the results it follows that when a soln. containing more than 0.3 mol. TlBr_3 per l. is satd. with TlBr at boiling, as above described, $\text{TlBr}_3 \cdot \text{TlBr}$ seps. on cooling; when the soln. contains from 0.15 to 0.3 mol., first TlBr , then $\text{TlBr}_3 \cdot 3\text{TlBr}$, then $\text{TlBr}_3 \cdot \text{TlBr}$ are formed; when the soln. contains less than 0.15 mol., first TlBr , then $\text{TlBr}_3 \cdot \text{TlBr}$ seps. The results previously obtained are those to be expected from the ordinary phase rule relations, assumptions in regard to a specific effect of sunlight or $\text{H}_2\text{C}_2\text{O}_4$ being unnecessary. Results similar to those previously obtained with $\text{H}_2\text{C}_2\text{O}_4$ were obtained with $(\text{NH}_4)_2\text{C}_2\text{O}_4$, but tartaric acid acts much more slowly than either of the above. The compds. $\text{TiCl}_3 \cdot 3\text{TiCl}$ and $\text{TiCl}_3 \cdot \text{TiCl}$ are less affected by temp. change, and the latter can be recrystd. from hot H_2O . With a large excess of TiCl_3 , $\text{TiCl}_3 \cdot 3\text{TiCl}$ is transformed into $\text{TiCl}_3 \cdot \text{TiCl}$, contrary to statements in the literature. Crystn. of solns. containing TiCl and TlBr_3 in varying amt. gave mixts. of varying Br content, showing formation of mixed crystals; the numerous double chlorides described in the literature do not exist.

GEORGE W. MOREY.

The passivification of iron by nitric acid (YOUNG) 9.

7. ANALYTICAL CHEMISTRY.

F. G. R. ARDAGH.

Volumetric determination of sulfuric acid. U. S. BORGHI AND T. SOTOLA. *Atti r. ist. Veneto* 72, II, 1097-1117(1912).—The authors modified Andrews' method, which depends upon the pptn. of H_2SO_4 by BaCrO_4 in HCl soln., and subsequent detn. of excess BaCrO_4 . In a flask or beaker of about 800 cc. a measured quantity of the

factory results on the detn. of inorg. P in blood, brain, flesh and liver, and was adopted in 1914 as official by the Association of Official Agricultural Chemists.

R. C. ROARK.

A new method for determining iodine in organic preparations. E. RUPP AND F. LEHMANN. Univ. Koenigsberg. *Arch. Pharm.* 253, 443-5(1916).—Recognizing the fact that only in exceptional cases is a direct detn. of I possible, numerous expts. were carried out to improve the very excellent method of Baubigny and Chavanne (Emde, *C. A.* 5, 2473), whereby I is estd. as AgI in the presence of Br and Cl. The procedure finally elaborated is as follows: In a 500 cc. Kjeldahl flask mix 25 cc. 0.1 N AgNO₃ with 20 cc. concd. H₂SO₄ and heat until the flask is filled with white acid fumes. After cooling add 2.5 g. finely powdered KMnO₄, then introduce the accurately weighed sample (contained in a small weighing capsule) into the oxidizing mixt. Should no energetic evolution of gas be immediately apparent, add 5 cc. H₂O, otherwise defer such addition until the reaction has nearly ceased. After the addition of H₂O, agitate vigorously 1-2 min., then allow the mixt. to stand 15 min. with occasional stirring. Now heat the flask (partially closed with a small funnel) in a slightly inclined position at first gently until the liquid boils, then strongly. By frequently turning the flask, any particles previously projected on to the neck are washed down again. Continue the heating until the MnO₂ has nearly disappeared and the liquid assumes a deep blue color. Allow to cool, pour on to the mixt. at one time a freshly prepd. soln. of 5 g. cryst. FeSO₄ in 100 cc. H₂O, shaking the product vigorously for some min. until the AgI has sepd. in cheesy masses and the supernatant liquor becomes clear. Transfer the contents of the flask to a large beaker, wash out the flask with 20-30 cc. H₂O in small portions and titrate *via* Volhard the unexpended AgNO₃ with 0.1 N KCNS. 1 cc. 0.1 N AgNO₃ = 0.0127 g. I.

W. O. E.

Formaldehyde containing copper. HERMANN KUNZ-KRAUSE. *Apoth. Ztg.* 31, 66-7(1916).—The adsorptive action of finely divided cellulose may be employed to detect every minute quantity of Cu in HCHO. Thus, on passing the sample (containing the metal possibly as formate) through a folded filter, that portion of the paper untouched by the liquid remains perfectly colorless, while the wetted portion shows after drying and especially in transmitted light a beautiful greenish blue sheen.

8. MINERALOGICAL AND GEOLOGICAL CHEMISTRY.

EDGAR T. WHERRY.

A modification of the reaction of Meigen for differentiating between calcite and aragonite. E. QUERCIGH. Univ. Turin. *Atti accad. Lincei* 24, I, 1231-5(1915).—The Meigen test for aragonite (*Centr. Min. Geol.* 1901, 577) depends on a lilac coloration when the powdered mineral is boiled a few min. with dil. CoCl₂ soln. With calcite a faint bluish deposit is formed. With aragonite (Meigen, *Z. Kryst. Min.* 44, 312(1908); *C. A.* 2, 519, 520) the deposit is 2CoCO₃ + 3Co(OH)₂ + H₂O; with calcite it is CoCO₃ + 3Co(OH)₂. Kreutz (*C. A.* 4, 1283) found that the ppt. on calcite is easily sol. in NH₄Cl soln. while that on aragonite is nearly insol., but Q. finds that if there is a difference in the soly. it is too slight to be of value. The Thugutt test (*C. A.* 5, 1382) with 0.1 N AgNO₃ and then with K₂Cr₂O₇ depends on the same principle as the Meigen test: the more rapid soln., and thus reaction, of the less stable phase. There are at least 2 weaknesses in the Meigen test: (1) It can not be effective with a mixt. of arago-

nite and calcite since, as was shown by Panebianco (*Riv. min. crist. ital.* 28, 5(1902)), 1 part aragonite in 19 of calcite gives the lilac tint. (2) It is only effective when the mineral is no more than slightly colored in such a way as to mask the lilac color and fails with the many specimens that are yellow or brown. Moreover it can not be known by this method whether calcite is present or not. Q.'s change in order to avoid these disadvantages is to transform the basic CoCO_3 into sulfide on the mineral, which with aragonite gives a black coloration very quickly and with calcite a gray coloration slowly. In a mixt. of the 2 minerals the granules are easily distinguished even with the unaided eye. 0.1 to 0.2 g. of the mineral are used but a few milligrams are sufficient. Pieces 0.2 to 0.4 mm. are used; they are boiled 1 min. with 5% $\text{Co}(\text{NO}_3)_2$ soln.; any concn. of Na_2S or $(\text{NH}_4)_2\text{S}$ soln. may be used. By this method many specimens gave a test for aragonite after Meigen's original test had failed. This test applied (prolonged action) to a washed and polished 110 face of a large crystal of Sicilian aragonite partly transformed into calcite showed distinctly the portions of the face so transformed. This test is now more satisfactory than Thugutt's. E. J. WITZEMANN.

Strongly thermophosphorescent calcite. F. PISANI. *Bull. soc. franc. min.* 38, 24-7(1915); *Chem. Zentr.* 1915, II, 673.—Continuing work in this field (cf. C. A. 8, 2136), P. announces that he has observed strong thermophosphorescence with only 4 additional specimens of calcite. These were obtained from Louverne (Mayenne), Andreasberg, Derbyshire, and from the vicinity of the Puy. E. A. TSCHUDY.

Reaumurite. A. LACROIX. *Bull. soc. franc. min.* 38, 16-21(1915); *Chem. Zentr.* 1915, II, 672-3.—Reaumur's porcelain was found to have been formed through the softening of glass vessels by molten lava during the destruction of St. Pierre in 1906. L. apparently considers this sufficient evidence that the substance is a true mineral. The piece of porcelain from St. Pierre had the following compn.: SiO_2 68.10, Al_2O_3 1.25, Fe_2O_3 0.15, FeO 0.22, MgO 0.03, CaO 16.96, Na_2O 11.38, P_2O_5 0.06, H_2O (105°) 0.60, H_2O (red ht.) 0.36, sum 99.11. The analysis leads to the adoption of the formula $2\text{SiO}_2(\text{Ca}, \text{Na}_2)\text{O} = (\text{Ca}, \text{Na}_2)\text{Si}_2\text{O}_6$. The rivaite of Zambonini (C. A. 9, 774) may possibly be identical with reaumurite. E. A. TSCHUDY.

Elba petalite. PROBO COMUCCI. Florence. *Atti accad. Lincei* 24, I, 1141-6 (1915).—The crystallographic measurements are given for this petalite. Chem. analysis showed SiO_2 77.58, Al_2O_3 18.25, Fe_2O_3 0.58, Li_2O 3.08, K_2O 0.38%. Calcg. the Fe as substituted isomorphously for Al_2O_3 , the latter becomes 18.62%. In ordinary petalite the $\text{Al}_2\text{O}_3:\text{Li}_2\text{O}$ ratio is 1:1 but in this it is 2:1. If 2 silicates are present ordinary petalite would be $(6\text{SiO}_2.\text{Al}_2\text{O}_3)(2\text{SiO}_2.\text{Li}_2\text{O})$ and this one $2(6\text{SiO}_2.\text{Al}_2\text{O}_3).(2\text{SiO}_2.\text{Li}_2\text{O})$. The supposed isomorphism between this petalite and spodumene could not be fully confirmed. [The above analysis yields approximately the usual petalite ratios. ABSTR.] E. J. WITZEMANN.

Ilvaite and other minerals from Perdu Niedda nell'Oriddese (Sardinia). ERNESTO MANASSE. *Atti accad. Lincei* 24, II, 285-9(1915).—The important Fe-bearing deposits of this region have been described by A. Ciampi (*Rass. min.* 30, 14(1909)). Some of the contact minerals which were supplied by C. are described. Ilvaite occurs in compact masses or with a radiating structure, pitch-black in color. On analysis it gives: H_2O 2.66, SiO_2 29.37, Al_2O_3 0.67, Fe_2O_3 19.47, FeO 27.74, MnO 6.48, CaO 13.25, MgO 0.51%, corresponding to $\text{Ca}(\text{Fe}^{\text{II}}, \text{Mn}^{\text{II}})_2(\text{Fe}^{\text{III}}(\text{OH}))(\text{SiO}_4)_2$ in which $\text{Mn}:\text{Fe} = 1:4$. Garnet is more abundant in these contact zones than ilvaite and occurs associated also with wollastonite and actinolite in segregation veins. The garnet is mostly dark green but sometimes rosin colored. The latter shows: SiO_2 35.09, Al_2O_3 2.01, Fe_2O_3 29.82, MnO 0.53, CaO 33.10, MgO 0.48%, no TiO_2 or Cr_2O_3 , corresponding to $\text{Ca}_3\text{Fe}_2^{\text{III}}(\text{SiO}_4)_3$. The wollastonite, occurring in white masses with a radiating fibrous structure,

shows H_2O 0.85, SiO_2 50.49, Al_2O_3 trace, Fe_2O_3 0.54, CaO 47.72 and MgO 0.51%, and corresponds closely to $\text{Ca}(\text{SiO}_3)$.
E. J. WITZEMANN.

Titanite and its pseudomorphs. A. LACROIX. *Bull. soc. franc. min.* 38, 21-4 (1915); *Chem. Zentr.* 1915, II, 671.—Large crystals of titanite from Ambalavaokely, Madagascar, had the following compn.: SiO_2 31.00, TiO_2 35.40, Al_2O_3 4.00, Ce_2O_3 0.40, FeO 1.60, CaO 27.20, loss on ignition 0.66, sum 100.26%. They originated in a pegmatite vein consisting of epidote and microcline. The upper surface of the crystals has undergone a change. A clear yellow substance (colloidal) in concentric layers has formed. This substance contains much Ti and some Ca. Its nature has as yet not been completely investigated. Pseudomorphs of titanite were found in a pegmatite deposit at Ambatofotsy associated with needles of rutile, small quartz crystals and mica scales. They had the following compn.: SiO_2 31.20, TiO_2 47.20, Al_2O_3 10.80, Fe_2O_3 6.60, MgO 1.84, K_2O 0.56, loss on ignition 1.30, sum 99.50. Xanthitane from North Carolina has a different compn.
E. A. TSCHUDY.

Brazilian anthosiderite and the similar pseudomorphs of Madagascar quartzite, containing magnetite. A. LACROIX. *Bull. soc. franc. min.* 38, 9-15(1915); *Chem. Zentr.* 1915, II, 672.—The anthosiderite of Hausmann is considered by Zirkel as a mixt. of biotite and fibrolite. According to Groth, it consists of andalusite and biotite. Dana, however, places it with hisingerite as a distinct species. An examn. of old museum material showed that the question resolves itself into a consideration of Fe-bearing pseudomorphs similar to cummingtonite in which most of the SiO_2 exists as primary quartz. The griqualandite of Hepburn is quoted in support of this conclusion. In certain quartzites from Madagascar golden-yellow fibers were found, being in some places so numerous that the rock had a silky appearance. In this case it was proved that the material in question consisted of completely transformed cummingtonite, containing grünerite and possibly hudsonite. The grünerite was easily identified optically.
E. A. TSCHUDY.

The beudantite of Laurion and the non-existence of lossenite as an independent species. A. LACROIX. *Bull. soc. franc. min.* 38, 35-8(1915); *Chem. Zentr.* 1915, II, 756.—A mass of beudantite consisting of small, almost spherical crystals, was analyzed and the compn. found to be: SO_3 12.30, As_2O_3 13.36, Fe_2O_3 33.09, Al_2O_3 2.63, PbO 30.65, H_2O 7.95, sum 99.98%. This corresponds to the formula $3\text{PbSO}_4 \cdot 4\text{Fe}_2\text{O}_3 \cdot \text{As}_2\text{O}_3 \cdot 9\text{H}_2\text{O}$. It also contained scorodite, which was so covered and pierced by the beudantite rhombohedrons as to make a sepn. of the two minerals impossible. L. considers this aggregate to be identical with the "lossenite" of Milch.

Unusual gas in a metal mine. E. STEIDLE. *Mining Sci. Press* 112, 368(1916).—S. reports on a gas mixt. found in mines in the Tonopah-Goldfield district of Nevada. Samples taken by the H_2O -displacement method had the following compn.: O 0.95 and 0.52, CO_2 0.65 and 1.08, N 98.4 and 98.4%. Apparently the evolution of this gas is associated with the genesis of the ore-deposits of the district. Nitrates have been found in the mine-waters, and the surrounding country is full of hot springs containing nitrates. The gas (locally known as "ground-gas" or "natural gas") was given off from the "water-

courses" and "vug-holes" in the ore bodies, and was not found in the country-rock. It collected in blind raises or in the tops of dead-end stopes. The physiological effect of breathing this gas is similar in every way to that produced by breathing pure N; the death of a workman is reported.

of stannite ore. *Eng. Mining J.* 101, 648-50(1916). tables, curves, and discussion, was under acid flux and, as such, can be used to hold in soln. the Ag. A Cu mat

Exhaustion of ore reserves and the failure of the reverberatory process which used up the funds for development work caused cessation of mining. L. outlines the following procedure for future treatment of stannite ore based on the experience at Zeehan and on lab. expts.: (1) A preliminary roast in mechanical furnaces, in part, or wholly, of the stannite ore, to be followed by blast roasting. (2) Smelting of the roasted products under reducing conditions producing Sn-Cu alloy, and sufficient 30% mat for the next operation. (3) Blowing the alloy and mat in the usual Cu converter into Ag-Cu bullion and volatilized SnO_2 , the latter to be collected in flue-chambers, which should be sufficient without a bag-house. (4) Reduction of the SnO_2 in a reverberatory or disposal to a smelter. *Analytical.* The usual scorification assay for Cu ores gives reliable results when run with a good fire and a little extra test Pb and borax. *Copper.* Treat with HNO_3 , evap. until pasty, dil., boil and decant through a filter, add a little HNO_3 and hot H_2O , stir the ppt. thoroughly, boil, let settle and decant through the same filter, wash the ppt. on to the filter and then wash several times with hot H_2O . Add H_2SO_4 to the filtrate containing Cu, take to fumes and proceed in the usual manner. *Tin.* Ignite the ppt. and fuse in a Ni crucible with Na_2O_2 , cool, dissolve out with H_2O , make acid with concd. HCl , then add 50 cc. in excess. Boil with about 25 g. Ni foil for 40 min., add a piece of marble, cool rapidly, add starch soln. and titrate with standard I soln.

F. W. SMITHER.

Treatment of antimony-gold ore. W. S. MANN. *Mining Sci. Press* 112, 433-4 (1916).—A note on mill-tests made in southern Mexico. The ore carried Au and Ag, with Sb, Pb, arsenopyrite and Cu as associated minerals. The free Au in the tailing was covered with a film of stibnite that prevented amalgamation with Hg. By treating with NaOH soln. the stibnite was dissolved and the Au readily amalgamated. By treating the original ore with a strong NaOH soln. and washing, it cyanided easily with a consumption of 2.6 lbs. cyanide per ton of ore. The ore was crushed in a 5% NaOH soln., amalgamated on Cu plates for the free Au, and then concd. The tailing from the concentrating tables passed through a long box with a traveling belt, which separated the sand from slime. The water was afterward removed from the fines in a spitzkasten and returned to one of 2 battery storage-tanks, where the Sb was pptd. The NaOH soln. was then brought up to strength and used over again. The sand was cyanided by percolation and the slime by agitation and decantation. The Cu, which went into soln., was taken care of by immersing the Zn shavings in a 10% (AcO), Pb soln. By maintaining the plates dry the tendency of the Pb to keep the amalgam soft was overcome.

F. W. SMITHER.

Effect of Zn_2Ag_2 upon the desilverization of lead. F. C. NEWTON. *Trans. Am. Inst. Mining Eng.* 51, 786-93 (1916).—Since the freezing-point curve of Carpenter upon Zn and Ag shows the existence of a definite chem. compd., Zn_2Ag_2 , with a freezing-point of 665° , large-scale expts. were undertaken with a view to forcing this compd. into the crust, hoping thereby to obtain a higher concn. than formerly. The expts. are reported in detail with tables and curves, from which N. concludes that, as a commercial project, the slight increase in doré contents of the crust, which might be obtained from zincing at the greater heat, is more than counterbalanced by the attendant disadvantages. The current practice dictated more or less by the question of fuel economy and better life of kettles, has been justified as a practical and efficient procedure from the standpoint

of concn. For comfort of operation, effect upon the men, etc., all arguments favor zincing at a lower temp. F. W. SMITHER.

Lead poisoning in the smelting and refining of lead. A. HAMILTON. U. S. Dept. Labor, *Bur. Labor Statistics*, Whole No. 141, 97 pp. (Feb., 1914); cf. C. A. 5, 2437; 7, 653; 9, 1878.—A detailed report and discussion based on a study of 20 U. S. plants. The methods employed vary according to the character of the ore handled, and the difference in hygienic conditions seems to depend more upon the different methods used than upon different standards in the management. Only 2 plants were found in which neglect and indifference were conspicuous, but no plant was found in which every obvious precaution had been used. The plants which have the greatest incidence of Pb poisoning are those in which unusually dangerous processes are used (2 exceptions due to carelessness in management). During 1912 the number of cases of Pb poisoning reported was 1769 (a rate of almost 22 for every 100 employed). The processes used in Pb smelting and refining in the U. S., the various furnaces used, and the flue dust system are described with 15 plates. Relative dangers of breathing Pb dust and of getting Pb on food, poisons other than Pb encountered in Pb smelting, Pb poisoning in the smelting industry in Great Britain, Germany, Austria, and U. S. are discussed. Appendices contain the N. J. Dept. of Labor regulations, together with the English, German and French regulations. Numerous references to the literature are given. Cf. Oliver, C. A. 7, 4012; 8, 3126. Clifford, C. A. 7, 1922. Stitt, C. A. 6, 2651. Thompson, C. A. 6, 2966. Thomason, C. A. 5, 513. Anon., C. A. 9, 1201. F. W. SMITHER.

The solubility of lead sulfide ores and of lead sulfide in human gastric juice. A. WOELFEL AND A. J. CARLSON. U. S. Dept. Labor, *Bur. Labor Statistics*, Whole No. 141, 82-4 (1914), Appendix 1; cf. C. A. 8, 3328.—The general plan of the tests is the same as that followed in the previous tests with white lead (cf. C. A. 7, 3519), with the exception of feeding expts. on animals. The PbS ores used contained 70.1 to 73.4% Pb. The expts. show that: (1) PbS is sol. in human gastric juice (averages about 2.5% for the ore; PbS from chem. dealers, 4.6%). (2) The soly. of PbS is less than that of basic lead sulfate (9.5%) or basic lead carbonate (46%), but the PbS is sufficiently sol. to be dangerous to the health of persons engaged in mining and milling PbS ore, if the processes involve the production of dust. (3) The persons engaged in mining and milling PbS ore should be protected in the same way as workers in other dangerous Pb industries. References to the literature are given. F. W. SMITHER.

Amalgamating copper plates. A. McLAREN. *Eng. Mining J.* 101, 647 (1916).—The following scheme of prepn. is suggested when it becomes necessary to use raw Cu plates with no supply of cyanide on hand. Scour the plate with tailings and wash clean. Dissolve a piece of Ag about the size of a dime in 20 cc. of HNO₃, boil until the red fumes are expelled, and add 150 cc. of H₂O. Pour this soln. over the plate, the surface of which becomes blackened. A few drops of Hg thrown on the plate and rubbed lightly will then produce a properly amalgamated surface quickly and easily. This procedure makes it possible to utilize old plates or sheets of raw Cu. F. W. S.

Tilting crucible furnace. ANON. *Engineering* 101, 276 (1916).—The crucible melting furnaces of the tilting type, described with illustrations, are designed primarily for oil-firing, but can also be used with coke and gas. The special features are the combustion chamber, the method of tilting the furnace, and the const. vertical pouring point. F. W. SMITHER.

Effect of borax in mat fusion. G. E. JOHNSON. *Eng. Mining J.* 101, 648-50 (1916).—The investigation, reported in detail with tables, curves, and discussion, was undertaken in order to prove (1) that borax acts as an acid flux and, as such, can be used to replace SiO₂; (2) that borax does not dissolve or hold in soln. the Ag. A Cu mat

containing 35% Cu and 17.3 oz. Ag was taken as the basis for the expt. Three types of charges were used: (a) Livingstone's charges for Cu mats (cf. *Eng. Mining J.* 98, 23(1913)); (b) L.'s charges in which borax glass replaces the SiO_2 ; (c) L.'s charges with enough borax added to raise the silicate-borate degree one unit. The conclusions are that borax will replace SiO_2 in a mat fusion without loss of Ag values, and that the silicate degree should lie between a $1/8$ silicate and a monosilicate. F. W. SMITHER.

Antimony in Hunan Province, southern China. A. S. WHEELER. *Eng. Mining J.* 101, 637-41(1916); *Mining Eng. World* 44, 697-9, 739-41(1916).—Excerpts from a paper read before the Institution of Mining and Metallurgy, London, Feb. 24, 1916. A review. The most important mines are in dolomitic limestone in the vicinity of Hsin-hua in the Hsi-k'eng-shan field. The world's annual production of Sb has risen from less than 18,000 tons in 1910 to probably over 40,000 tons at present. Also in *Mining Eng. World* 44, 697-9, 739-41(1916). F. W. SMITHER.

Metallurgy of the ores from Cobalt, Ont. R. W. BRIDGES. *Canadian Mining J.*, Jan. 15, 1916; *Eng. Mining J.* 101, 646-7(1916).—An account of the operations of the Co plant of the Canadian Copper Co., Copper Cliff, Ont. The works were remodeled and designed to smelt and treat ores and concentrates from the Cobalt Ag district. The ore is crushed and ground in Krupp ball mills to pass 30-mesh; for sampling about 6% was cut by a Snyder sampler. The ore was charged with suitable fluxes into 32×72 in. blast furnaces having a capacity of 25 to 30 tons per 24 hrs. Michigan limestone was used as the basic flux, low grade Crown-Reserve ore as the acid flux. The products of the blast furnaces were: (1) flue dust and crude As, (2) slag, (3) Ag bullion, (4) speiss. The crude As and flue dust from the blast furnaces and roasting furnaces were collected in suitable condensing chambers; the dust was recharged to the blast furnaces, and the crude As sublimed from As refining furnace ready for packing. Pure white As_2O_3 assayed 99.98% As_2O_3 with about 0.03 oz. of Ag per ton. The slag from the blast furnaces during ore runs was rejected except when it contained more than 10 oz. of Ag per ton, in which case it was returned to the blast furnaces. The slag produced while smelting speiss to remove the Fe was all used on ore runs owing to its high Ag and Co content. Assays of the slags showed in oz.: ore slag: Ag 8.8, As 0.13, Co 0.44, Ni 0.29, Fe_2O_3 11.63, Al_2O_3 14.15, CaO 22.78, MgO 8.67, SiO_2 41.13; speiss slag (same sequence): 32.8, 0.47, 13.97, 1.28, 28.54, 9.75, 6.50, 4.68, 34.03. About 75% of the Ag in the ore charged was obtained as buttons, which were easily sepd. from the speiss and charged into an oil-fired cupeling furnace of 30,000 oz. capacity. The crude Ag assayed about 860 fine. After about 24 hrs. in the cupeling furnace it was ladeled out 994 fine and sent to the Balbach Smelting and Refining Co. The speiss was brittle as a rule, and easily broken with a hammer. After crushing it was ground in the ball mill to 30-mesh, 20% of NaCl being added as the speiss was charged to the mill. This high-Fe speiss was roasted in 8 Edwards reverberatory furnaces fitted with mechanical rabblers and having a capacity of 2400 lbs. per 24 hrs. The compn. averaged: 25.2% Co, 15.3 Ni, 31.3 As, 16.1 Fe and 1480 oz. Ag per ton. The product of the roasting (a chloridized speiss) was transferred from the smelter to the hypo-leaching building, and treated in a large agitation cylinder first with cold H_2O to dissolve out the undecomposed NaCl and the sol. salts of Co, Ni, and Cu. This H_2O soln. was decanted onto scrap Fe to ppt. the Cu and then pumped to another tank, where the Co and Ni were pptd. as hydroxides by NaOH. This ppt. was dried, calcined to oxides, ground and barreled for shipment. It assayed: Ag 15.0 oz., As 0.3%, Co 40, Ni 3%. As Ni is less easily converted to a sol. salt in the chloridizing roast, it is lower than the usual proportion of Ni to Co. After the H_2O wash, the speiss is treated 4 times with $\text{Na}_2\text{S}_2\text{O}_3$ soln. to dissolve the AgCl, giving the "first hypo residue," which contains 20 to 30 oz. of Ag. The Ag was pptd. from the $\text{Na}_2\text{S}_2\text{O}_3$ soln. as Ag_2S , collected in a filter

press, dried, mixed with NaNO_3 and Na_2CO_3 , roasted in an oil-fired furnace, and leached in hot H_2O . The residue (a sponge-like mass of Ag) was charged to the Ag-refining furnace. The "first hypo residue" was returned to the smelter, mixed with quartz and run through the blast furnaces to remove Fe (the selling contract calling for less than 5% of Fe in the "crude Co material"), the resulting green speiss ("low Fe speiss") carrying about Co 28.9%, Ni 27.8, As 29.5, Fe 3.5%, Ag 1341 oz. This speiss was milled with NaCl and roasted just as the "high Fe" speiss, washed with H_2O , and treated with $\text{Na}_2\text{S}_2\text{O}_3$, giving the "second hypo residue." It was dried, mixed with 20% NaNO_3 and 10% Na_2CO_3 , and roasted in a reverberatory furnace, converting the As to Na_3AsO_4 , which was leached out with hot H_2O . The dried residue was sold to German refineries as "crude Co material;" average analysis: Co 30.7%, Ni 28.5, As 1.1%, Ag 34.6 oz. per ton. Elec. power was used. From Dec., 1905, to Feb., 1913, more than 40 mil. oz. of Ag, 2.2 mil. lbs. of Co, 1.5 mil. lb. of Ni, and 4.5 mil. lbs. of pure As_2O_3 were produced.

The passivification of iron by nitric acid. S. W. YOUNG AND E. M. HOGG. *J. Phys. Chem.* 19, 617-49 (1915).—An extensive series of velocity detns. of the reaction between Fe wire and HNO_3 were made. The d. of the acid ranged from 1.025 to 1.400; the measurements were duplicated for 0° , 10° and 20° . As the results at 0° do not differ materially from those at 10° or 20° , satisfactory conclusions may be drawn from the data at 0° . A. *Passivification by HNO_3* : (1) The value of the velocity const. for the reaction between Fe and HNO_3 decreased with increasing concn. of acid; (2) this decrease is not uniform, but shows a rapid drop when the d. of the acid is 1.260; (3) In concns. greater than 1.260 the velocity const. decreases with the time—an indication of passivity; (4) this concn. 1.260, called the point of "passive break," is the point at which progressive passivification begins, and also the point at which a rapid decrease in the reaction rate takes place; the "passive break" is not independent of the temp., it falls from 0° to 10° and rises to 20° ; (6) passivifying acids, no matter how concd., slowly but steadily dissolve Fe. B. *Passivification by NO_2* : (1) Dry NO_2 is a stronger passivifying agent than HNO_3 ; NO is without effect; (2) passivifying acids contain

more or less of the higher oxides of N, while activifying acids are generally water-white; (3) activifying acids lose their power on repeated use, due presumably to the accumulation of dissolved NO_3 ; bubbling NO_2 through activifying acids, or adding nitrites, produces passivity; (4) Fe, passivified in NO_2 , absorbs some of the gas; (5) it is likely that but little NO_2 is necessary for passivification. *C. Conception of the Passive State:* (1) The passive state is not definite, since there exist an indefinitely great number of degrees of passivity; (2) the state seems to be the result of an equil. between Fe and NO_2 —Fe absorbs NO_2 from any soln. in which it is produced, and the rate of reaction is thereby inhibited; (3) since Fe passivified by dry NO_2 is more passive than that which is passivified in HNO_3 , it would seem that Fe absorbs little NO_2 from even concd. HNO_3 ; the "passive break" may be regarded as that concn. at which the reaction begins to develop relatively large amounts of NO_2 . D. B.

Effects of blooming on rails. M. H. WICKHORST. *Iron Age* 96, 1317(1915).—The influence on rails of the manner in which the bloom is rolled was studied, particularly with reference to the transverse ductility of the bottom of the base of the rail. It was found that rails rolled *top in top* gave about the same results as those rolled *top in web* in the drop tests, transverse tests of the base, and tensile tests. The results were also about the same for the various rates of reduction in making the bloom, except that in the drop tests with the base in tension there was a general decrease in ductility as the rate of initial reduction increased; there was, however, considerable irregularity in the results. W. T. H.

The initial structure of steel castings. EDWIN F. CONE. *Iron Age* 96, 1294-6(1915).—The slower the cooling and the greater the bulk of metal, the greater is the tendency to produce large crystals or octahedral structures called ingotism. There is no ingotism to correct if the sand cooling is rapid and is followed by annealing at the recalescence temp. On the other hand, if the sand cooling is slow, ingotism is not easily remedied and a heavy test section will show more of it than a thin one. W. T. H.

An investigation of ladle test ingots. ROBERT W. HUNT. *Iron Age* 96, 1303-5(1915).—It is recommended that rail specifications should provide a standard shape and size for ladle test ingots with directions as to size of drill and locations of the borings from which the chem. analysis is to be made and that Al, preferably in the dipper, should be added when necessary to insure a sound setting steel in the ladle test ingot with freedom from blow holes. Unsoundness of the ingot renders the chem. analysis inaccurate. The location of the test ingot in the heat with respect to the regular ingots cast is also worthy of consideration. The reasons for arriving at the above conclusions are discussed at length. W. T. H.

The Bontempi rust-proofing process. ANON. *Engineering* 100, 602(1915).

W. T. H.

Volume changes during the hardening of steel. E. H. SCHULZ. *Engineering* 100, 596-7(1915).—It was found that the d. of annealed steel decreased as C increased. The d. was decreased by quenching, the more as the C content was high. The vol. changes produced by oil quenching were always less than with H₂O. On the whole, the results obtained by S. agree with the observations of Heyn and Bauer on the soly. of steel in acids but they do not fit the allotropic theory. On quenching, martensite needles are formed in austenite, which is at first compressed by them; but the decompn. of martensite begins at 100° and above 150° austenite becomes able to take up the compression stress and is itself decomposed in the range 250-450° in which the martensite decompn. is completed. On the other hand, rising temp. expands both martensite and austenite and as the expansion predominates in the interior, which is still in the annealed state, while contraction goes on in the cooled surface, hardness cracks are developed. Stresses play an important part in hardening. These are either purely physical or thermal, or else they are brought about by the different natures and vols. of the different constituents and their textures. The complete relieving of these stresses will only be accomplished in small pieces. Eutectoid steels are very likely to develop hardness cracks because all the transformations take place at 700° and not in several stages.

W. T. H.

Chisels. HENRY FOWLER. *Engineering* 101, 195(1916).—The Midland Railway (English) specifies that chisels should contain 0.75-0.85% C with other constituents present in normal amts. A satisfactory chisel was found to contain 0.75% C, 0.38% Mn, 0.16% Si, 0.028% S, 0.026% P. The chisels are hardened by heating to 730° followed by quenching to a depth of $\frac{3}{8}$ to $\frac{1}{2}$ in. from the point in water and then cooling in linseed oil which is surrounded by running water. The hard point is then immersed in oil at 215-220° until the desired temper is obtained and then the chisel is removed, cleaned in saw dust and cooled in a tray.

W. T. H.

Stress distributions in engineering materials. J. PERRY, *et al.* *Engineering* 100, 379-80(1915).—The physical properties of mild steel are discussed and considerable data concerning the strength of the material is given.

W. T. H.

The influence of oxygen on some properties of pure iron. WESLEY AUSTIN. *Engineering* 100, 455-6(1915).—Highly oxygenated alloys were prepared by melting Fe and Fe₂O₃ in a small Girod furnace using a bundle of Fe rods as the movable electrode. The Fe was oxidized by the air during melting and additions of Fe₂O₃, MgO and CaO were made from time to time. The melt was cast in a clay pot; when cool was sawed through the center and the two halves forged into sq. billets, which were subsequently rolled into flat bars. The alloys were analyzed by heating in pure H and weighing the resulting H₂O. None of the material thus prepared contained more than 0.29% O. The m. p. was not noticeably different from that of pure, electrolytic Fe. Cooling curves taken *in vacuo* failed to show the pearlite point. The alloy resisted atm. corrosion very well but corroded more than mild steel in dil. acids and in sea water and more than wrought Fe in sea water. Photomicrographs show that the O is present in mechanical admixture.

W. T. H.

The use of alloy steels. ANON. *Engineering* 100, 548-9(1915). W. T. H.

The chemical and mechanical relations of iron, molybdenum and carbon. J. O. ARNOLD AND A. A. READ. *Engineering* 100, 555-7(1915); cf. C. A. 9, 1295, 1742.—Mo steels were prepared from Swedish bar-Fe and pure Mo in the ordinary commercial manner. The ingots were cast into molds about 2 in. sq. and when cold were reheated and hammered into bars $\frac{3}{4}$ in. round. The bars were annealed at 800°. From the steel, carbides were isolated by the electrolytic method. The chem. analysis was accomplished volumetrically with KMnO₄ after reducing both Fe⁺⁺⁺ and Mo⁺⁺⁺ with amal-

gamated Zn and at another time only Fe^{+++} with SO_4 . When about 18.25% Mo is present, Fe_3C disappears from the alloys and a double carbide, $\text{Fe}_3\text{Mo}_3\text{C}_3$, takes its place which is non-magnetic and is characterized by remarkable stability. Hardening expts. served to convert all the C into solid soln. Besides the double carbide, 2 other micro-constituents have been discovered in Mo-steels, namely Fe-Mo-pearlite and Fe-Mo-hardenite. The effect of Mo on steel resembles that of W only as regards the similarity in the thermal range of the transformation of pearlite into hardenite, which begins at about 925° and is completed at about 1100° . The steel-hardening power of Mo is 2 or 3 times that of W but the latter element is much more reliable in its action. Annealed Mo-steels are distinctly inferior in mechanical properties to annealed W-steels. Unlike W-steels, Mo-steels liberate the double carbide pure with a weak electrolyte and low current d. Within the limits tested, Mo does not appear to form a definite molybde of Fe corresponding to the tungstide Fe_3W . Just as high V facilitates the segregation of V-cementite, so high Mo appears to favor segregation of Fe-Mo-cementite in annealed steels. Fe-Mi-hardenite also resembles Fe-V-hardenite in brittleness when quenched above the temp. of complete transformation. W. T. H.

Heat treatment of steel. E. D. CAMPBELL. *Eng.* 100, 681-3(1915); *Electrician* 76, 27-30(1916).—Bars of different steels were heated electrically and quenched in ice-water; the spec. resistances were measured at 20° . One set was quenched from 1103° , the other from 892° . The latter were reheated to temps. varying from 105 to 800° . The results indicate that the sp. resistance increases with the temp. of quenching, as would be expected if the mol. wt. of the dissolved carbides is lowered by progressive dissociation. Another indication is the increase in sp. resistance of hypo-eutectoid steel when reheated to 800° and slowly cooled, when compared with the results on the same sample reheated to 600 or 700° . This is understood if one remembers that in samples reheated to 700° the carbides are slowly precipitating from a homogeneous, unsatd. solid soln., and while this pptn. would probably not be quite as complete as on cooling slowly from 800° , the carbides which do ppt. would give a higher mol. wt. than those from a satd. soln. and would contain little or no Fe in solid soln. In the case of a metal cooled from 800° , sepn. of nearly pure ferrite would take place before the recalescence was reached, so that the carbides pptd. during recalescence would do so from a satd. soln. The resulting cementite would consist of a satd. solid soln. of Fe in Fe carbides, tending to increase the sp. resistance. A steel bar was heated to 892° , quenched, and reheated to various temp. After each heat treatment drillings were taken and examd. colorimetrically for the amt. of dinitro derivatives due to carbides in solid soln. Clear correlation exists between the sp. resistance and the concd. carbides in solid soln. Applying the theory of dissociation in aq. soln. to solid soln., we may consider that the solute dissociates into "ionoids." In a metallic soln. practically all the conductance is through the solvent and undissociated solutes, while the "ionoids," although tending like ions to acquire energy in the form of elec. charges, are unable to retain the latter because of the nature of the solvent; therefore this energy is dissipated in the form of heat. Thus the elec. energy transformed into heat by the "ionoids" may be expressed in terms of sp. resistance; hence the ionic concn. in solid soln. may be detd. by deducting from the total sp. resistance that due to the solvent and undissociated solutes. D. B.

The heat treatment of iron and steel in a neutral atmosphere. ALFRED H. WHITE and HOMER T. HOOD. *Am. Gas Light J.* 103, 310-1, 314-5; *J. Gas Lighting* 132, 138-40; *Chem. Eng.* 23, 33-7(1915).—It is shown experimentally that it is possible to heat Fe and steel in an internally fired muffle, even to forging temp., without any oxidation or formation of scale on the surface of the metal. A neutral atm. is obtained by mixing illuminating gas with twice its vol. of air; the mixture will not burn unless

preheated. A slight decarburization takes place in steel heated in this gaseous mixture but at the temps. ordinarily used in the heat treatment of steel the effect is negligible.

Gas as a case-hardening agent. ALFRED H. WHITE AND HOMER T. HOOD. *Am. Gas Light J.* 103, 259-63, 66; *J. Gas Lighting* 132, 312-5(1915).—Illuminating gas is a good carburizing agent but it has been claimed that the case is too hard and too sharply defined when the carburization is effected with gas at a high temp. and for a short time. If, however, the gas is turned off and the hot metal allowed to *soak* in the furnace, there will be diffusion of C toward the interior of the piece of metal and any desired type of case-hardening can be effected. The use of NH_3 is not recommended on account of the danger of producing a brittle nitride of Fe.

The microstructural changes accompanying the annealing of bronze (Cu 0.88, Sn 0.10, Zn 0.20). H. S. RAWDON. *J. Ind. Eng. Chem.* 8, 109-14(1916); *Bur. Standards, Tech. Paper No. 60*, 17 pp.(1915); see *C. A.* 9, 3205. W. T. H.

The occurrence and influence of nitrogen in iron and steel. N. TSCHISCHESWSKI. *Engineering* 101, 171-3, 217-9(1916).—When Fe, Mn or Al is heated and exposed to the action of NH_3 , considerable N is absorbed with the formation of nitrides. With Fe the temp. optimum is about 600° and about 8.9% N will be taken up at this temp. In the case of Fe nitride, the N is obtained almost entirely as NH_4Cl when the metal is dissolved in HCl. To det. N, therefore, T. dissolves 0.3-0.7 g. of the sample in a small, covered Erlenmeyer flask with 10 cc. concd. HCl, heating slightly after the greater part of the Fe has dissolved. The soln. is rinsed into a 500 cc. flask which is connected with a condenser that leads to a receiver containing 25 cc. of 0.1 N H_2SO_4 . The HCl soln. is treated with 14 cc. KOH (1:1) and 40 cc. of satd. $\text{Ca}(\text{OH})_2$ soln. which serves to prevent bumping during the distillation. About 200 cc. of distillate is collected, or the distillation is continued, until the runnings give no test with Nessler's reagent. The distillate is then titrated with 0.1 N NaOH or it is treated with iodide-iodate soln. (250 cc. H_2O , 2.2 g. KIO_3 , 5.5 g. KI) and the liberated I titrated with $\text{Na}_2\text{S}_2\text{O}_3$ soln. The latter method is not recommended when more than 0.5% N is present. The Nessler test is not always reliable for when much C is present some amines are likely to form which have varying effects upon the Nessler test. With 98% Mn, 20% N was absorbed by heating with NH_3 ; this corresponds to the formation of MnN and the optimum temp. is $600-800^\circ$. When detd. by titration only 14.4% N was obtained and considerable N was evolved as such. Expts. proved that MnN dissolves to some extent in steel. At 1400° Si heated in N forms the very stable Si_3N_4 . This compd. is scarcely affected by dil. acids. When Si is present, therefore, considerable error is introduced into the N detn. unless the insol. residue is examined. With Al it was found possible to obtain AlN and the presence of this compd. appears to be a cause of bad steel. Under the microscope, crystals of Fe_3N with 2.02% N were noticed in the examn. of steel. This substance forms a solid soln. with Fe and on cooling steel this soln. separates into ferrite and Fe_3N . The solid soln. is very hard and brittle. The effect of N is more apparent, therefore, in steel which is to be tempered. Mechanical tests proved that the presence of N has a considerable effect especially with regard to the elongation. The hardness of the metal is increased and the elasticity reduced when the solid soln. is present. Commercial Fe and steel contains much less N than the specimens used in

these expts. but it is shown that even a little N has a considerable influence upon the desirable mechanical qualities. W. T. H.

Chemical, electrochemical and metallurgical industries of Scandinavia 18. Production of radium, uranium and vanadium (Hess) 3.

Ore-separator. G. H. DAVIS. U. S., 1,175,616, Mar. 14.

Apparatus for separating ores by flotation. F. B. KOLLBERG and M. KRAUT. U. S., 1,174,737, Mar. 7.

Flotation separation of ores. J. M. CALLOW. U. S., 1,176,428, Mar. 21. H_2O , frothing material and comminuted ore are placed in a closed flotation tank with pipes extending from its bottom into a shallow H_2O -seal and by applying suction to the top of the tank bubbles of air are drawn through the soln. and as they burst at the surface they carry off the floated particles.

Extracting and concentrating ore values. E. R. HOLDEN. U. S., 1,175,867, Mar. 14. Pulverized ore mixed with a solvent liquid is given a rotary motion in a tank so that various constituents of the ore, according to compn. and size are elevated to different levels in the tank by the rotating liquid and different portions or levels of the soln. and suspension are successively withdrawn, beginning at the top.

Concentrating ores. E. GAYFORD and G. CREER. U. S., 1,176,441, Mar. 21. Ore mixed with H_2O and a frothing agent is ground successively in a series of ball or pebble mills and between each grinding and the succeeding one the mixt. is aerated and the concentrates are floated off.

Concentrating copper in tailings. R. M. ATWATER, JR. U. S., 1,175,331, Mar. 14. Heaps of Cu tailings are treated with crude H_2SO_4 equal in wt. to the Cu present and exposed to the action of sunlight in a dry atm. until the Cu dissolved comes to the surface by capillarity and forms a solid concentrate at the surface which may be sepd.

Furnace for nodulizing ores. A. G. JONES and J. T. JONES. U. S., 1,174,727, Mar. 7. Sulfide, oxide or carbonate ores to be nodulized or reduced are mixed with wood, coal, coke or charcoal and fed from a hopper through a preheater, into a vertical shaft furnace into the upper end of which a limited supply of air is injected by a blower. Combustion gases are discharged into the stack and nodulized ore, ash, etc. is discharged into a water bath in which the ore and metal settles and is thus partly sepd. from ash.

Furnace for roasting ores. J. LÖTJENS and W. LUDEWIG. U. S., 1,176,070, Mar. 21. Superposed vaulted hearths are provided with stirring arms and rabblers curved to conform to the curvature of the hearths.

Furnace for reducing iron or copper ores. A. G. JONES. U. S., 1,174,728, Mar. 7. Oxide or carbonate ore mixed with wood or coal is fed through a revolving preheater into the furnace. Air is supplied to produce a reducing flame. Pb and Zn ores may be treated by adding a condenser to the app.

Apparatus for reducing copper ores. T. J. LOVETT. U. S., 1,175,966, Mar. 21. The ore is carried on rotating bed-plates while treated with pressure plates to sep. free Cu from gang.

Recovering copper, iron or other metals from ores. A. G. JONES. U. S., 1,174,729, Mar. 7. Oxide or carbonate ore of Fe, Cu, Mn, Ag, Pb or Zn mixed with fuel is fed

through a rotating preheater *B* into the furnace *C*, which is supplied with air through the tuyère *9* (cooled at its lower end with a water coil) and lower tuyères *7*. Combustible gases from the furnace are burned with air fed through the pipe *12* to maintain the temp. of the preheater and a slide *14a* controls the discharge of reduction products. In treating volatile metals such as Pb or Zn a condenser may be used.

Reducing ores of lead and zinc. A. G. JONES. U. S., 1,174,730, Mar. 7. A mixt. of fuel with Pb or Zn ore is fed from the hopper *7* into the furnace chamber *2* until the upper surface of the charge is in the position of the lines *15*. Air is supplied through tuyères *9* and volatilized Zn or Pb is led off through the outlets *3a* and *3b* to a condenser. Metal remaining in the furnace passes from the depression *6* into the collecting pit *6b* and a slide *4*

regulates the discharge of gang through the openings *5*. Any excess of coke discharged with the gang is used with a succeeding charge to recover any metal which it may have absorbed. *10* is a cooling coil.

Reducing lead or zinc ores. J. T. JONES and A. G. JONES. U. S., 1,174,731, Mar. 7. A furnace of the structure shown in Pat. 1,174,730 (*supra*) is used for heating the ore with fuel under such temp. conditions as to volatilize the metal values without fusing the gang. Combustible gases from the furnace are burned with air from a tuyère and volatilized metal values passing into chambers are washed by sprinkling jets into the collecting pit. The stack is so proportioned as to permit operation by natural draft.

Furnace for reducing ores. J. T. JONES and A. G. JONES. U. S., 1,174,732, Mar. 7. Ore is supplied from a hopper through an inclined chute passing through a chimney through a rotating preheater to a furnace of the structure shown in Pat. 1,174,729 (*supra*).

Refining copper mat containing lead. N. V. HYBINETTE. U. S., 1,175,266, Mar. 14. Cu mat containing sulfides of Pb and other metals is melted and successively passed from one to another of a series of separating kettles. Pb is drawn off from the bottom of the first kettle and the mat from the last kettle is bessemerized and then passed in a reverse direction through the separating kettles.

Reducing ores. F. E. AGNEW. U. S., 1,174,464, Mar. 7. Ores of Cu, Pb, Fe or Sb or other metals are reduced in a continuous process by first preheating the ore, with exclusion of air, to the reduction temp. of the metal which it contains and then passing it into a heat-insulated reduction furnace, from which also air is excluded and to which vaporized oil or other gaseous hydrocarbon is supplied at ordinary temp. After reduction the material is passed through a cooler in a non-oxidizing atm.

Furnace for melting metals. E. BOSSHARDT. Fr., 477,961, Mar. 8, 1915.

Extracting metals and alloys. E. KARDOS. Brit., 22,946, Nov. 23, 1914. In the extn. of metals and alloys from the ore by injecting a charge of powdered material into furnaces by means of a blast, the blast is controlled with respect to the compn. of the charge so as to generate reducing gas only, and the reaction is completed in a single closed chamber. The blast may be enriched with O or admixed with a reducing gas, and the spent gases may be returned to the chamber or used for industrial purposes. The production of alloys of Fe with Ni, Cr, and W is mentioned, the additional metals being added to the charge either in the free or combined state.

Heat treatment of manganese steel. MANGANESE STEEL RAIL CO. Fr., 477,880, Mar. 4, 1915. The product is heated up to or slightly above the critical point (825–850° for ordinary Mn steels) in order to redissolve the elements which have sepd. from the cryst. mixt. of steel and Mn, maintained at the max. temp. until equil. has been established, and finally cooled rapidly to the ordinary temp.

Apparatus for treating roasted minerals with liquids. A. RAMÉN. Fr., 477,906, Mar. 5, 1915. The process is devised with a view to facilitating the subsequent extn. of the roasted mineral. The roasted product, while hot, is placed in a finely divided state, on a movable table, and is sprinkled with a suitable quantity, distributed as uniformly as possible over the surface, of liquid from a previous extn. The substances rendered sol. by the liquid, as a result of the chem. or physical action on the roast, are recovered separately by subsequent extn.

Pure aluminium. A. LAMBERT. Fr., 477,988, July 10, 1914. In the extn. of the total Al, in a pure state, from bauxite, this mineral is decomposed by CaO or CaCO₃ in sufficient quantity to convert all the Al into Ca aluminate, operating in the elec. furnace, the Ca aluminate being then converted into sol. aluminate from which Al(OH)₃ can be pptd.

Pure aluminium. M. BUCHNER. Fr., 477,925, July 7, 1914. In the extn. of pure Al from argillaceous and other aluminiferous materials, especially those containing SiO₂ and Fe₂O₃ as impurities, the material, disintegrated by means of an acid, is treated, after removal by filtration of the silicic acid, with NH₄OH which gives an NH₄ salt, the ppt. is sepd. by means of an alkali and the Al is extd. with an alk. soln. in the usual manner.

Protecting copper from corrosion by sea water. G. KURTH. U. S., 1,176,571, Mar. 21. Fe filings are rolled into the surface of Cu or Cu alloys while cold and the surfaces are then subjected to electrolytic action to protect them from corrosive action by sea water.

Aluminium alloy for resisting sea water. W. N. NAYLOR and S. P. HUTTON. U. S., 1,175,655. Mar. 14. Al, Mg and phosphor-Sn are combined, preferably in about the proportions 1000:4:1. A small addition of Na may be made to form a dental alloy.

Alloy for valves of internal-combustion engines. W. E. OAKLEY. U. S., 1,175,172, Mar. 14. Internal-combustion engine valves are formed of an alloy of Ni 67, Cu 28–32 and Fe 1–5 parts, nearly free from C. The alloy has approx. the same coeff. of expansion as the cast Fe of the engine cylinders and is but slightly affected by the highly heated gases.

Tungsten welding contacts. A. M. STANLEY. U. S., 1,176,614, Mar. 21. Contact points of W or Mo are used for electrically welding sheets of metal under high pressure. The point is mounted in a carrier block of Cu and is but slightly affected by the O of the air at the high temps. to which it is exposed.

"Fix compound" for use in puddling and basic open hearth furnaces. J. F. DEAY. U. S., 1,175,933. Mar. 21. A mixt. of comminuted Fe 9, Portland cement 2 and CaO 1 part is used to form blocks or lumps to supply CaO to the metal for purifying it.

Zinc-surfaced bearings. J. RIDDELL. U. S., 1,176,603, Mar. 21. Bearings of Fe or steel are superficially alloyed with Zn, to produce a thin alloyed wearing surface, by sherardizing.

10. ORGANIC CHEMISTRY.

C. A. ROULLER.

Nitromercaptides and their reaction with the alkyl iodides. Compounds of the disulfonium series. PRAFULLA C. RAY. Calcutta. *J. Chem. Soc.* 109, 131-8(1916); cf. *C. A.* 9, 2889.—A study of the action of $\text{Hg}(\text{NO}_3)_2$ on mercaptans and of the action of alkyl iodides on the compds. formed. A dil. alc. soln. of the mercaptan is added, with stirring to a fairly concd. soln. of an excess of Na Hg nitrite. The soln. becomes warm, N_2O_3 is liberated, and nacreous crystals are deposited. *Methyl nitromercaptide* (A), MeSHgNO_2 ; *ethyl nitromercaptide* (B), faintly yellow, almost insol. in H_2O , sol. in HCl with evolution of N_2O_3 and the garlic-like RSH odor. (B) and excess of EtI on the H_2O bath for 2-3 hrs. give 2 layers, the upper yielding EtI, EtNO_2 , EtONO , and a dark brown syrup, while the lower deposits crystals of at least 3 substances. These are dissolved in acetone and a small first fraction, *ethylidisulfonium mercuriiodide*, $\text{Et}_2\text{S}_2\text{HgI}_2\text{EtI}$, pptd. with Et_2O , yellow crystals, m. 112° ; the structure EtISEt-SEtI.HgI is assigned. The analysis was made by heating in a stream of CO_2 , absorbing the evolved I in powdered Cu, and boiling this with aq. NaOH to yield NaI. (B) and MeI gave the compound $\text{Et}_2\text{S}_2\text{HgI}_2\text{MeI}$, pale yellow crystals, m. 86° . (A) and EtI gave 3 layers, from the middle of which, on soln. in acetone and pptn. with Et_2O , was obtained the *disulfonium compound*, $\text{Me}_2\text{S}_2\text{HgI.EtI}$, yellow crystals, m. $69-71^\circ$; no other definite products were isolated. *Compound*, $\text{Et}_2\text{S}_2\text{HgI.PrI}$, pale yellow crystals, m. $75-8^\circ$; *compound*, $\text{Me}_2\text{S}_2\text{HgI.PrI}$, yellow crystals, m. $99-102^\circ$. On stirring an alc. soln. of Et_2S_2 into $\text{Hg}(\text{NO}_3)_2$ soln., N_2O_3 is evolved and needles of the compound $\text{Et}_2\text{S}_2\text{Hg}(\text{NO}_3)_2\text{HgO}$ are deposited. The reaction is supposed to take place by the addition of 2 mols. $\text{Hg}(\text{NO}_3)_2$ to the Et_2S_2 , followed by evolution of N_2O_3 and deposition of the resulting $\text{EtS}(\text{HgNO}_3)\text{SEt}(\text{NO}_3)\text{Hg.O}$. M. HEDLBERGER.

Oxidation of unsaturated fatty oils and unsaturated fatty acids. I. Formation of acrolein by the oxidation of linseed oil and linolenic acid. ARTHUR H. SALWAY. Port Sunlight. *J. Chem. Soc.* 109, 138-45(1916).—It is held that one reason for the failure to obtain conclusive results as to the nature of the processes taking place during the oxidation of linseed oil is the fact that the oil is a mixt. of glycerides, and that a study of the pure unsatd. glycerides contained in the oil, or a study of the pure fatty acids obtained from these, would be more likely to yield definite results. It is proposed to carry out investigations along these lines. The oxidation expts. were carried out at 100° in a U-shaped pipette with O under 2 atms. pressure, the pipette being mechanically agitated. When the pressure had been reduced to 1 atm. the gaseous products of the oxidation were passed through H_2O and the process repeated until the absorption of O had almost ceased. The absorption of O was slow for the first 20 min. but then continued rapidly until about 5 l. O per 100 g. linseed oil had been absorbed. The wash water was free from acid and had the characteristic odor of acrolein (A), which was further identified by oxidation with Ag_2O and isolation of the Ag acrylate. Dunlop and Shenk (*J. Am. Chem. Soc.* 25, 826(1903)) considered the odor of (A) noted by them to be due to the action of O on the glycerol in the oil, but that this is due to

the linolenic acid itself is shown by the fact that, while neither glycerol nor oleic acid yields (A), linolenic acid does. The mixed fatty acids from the oil gave a still higher yield of Ag acrylate. The formation of (A) is explained as follows, using a structure for linolenic acid differing from that assigned by Erdmann (C. A. 3, 2165; 5, 1086):

This view also accounts for the evolution of CO and CO₂ observed by Gardner (C. A. 8, 1677) and King (C. A. 9, 1848). The theory is also advanced that the aldehydes formed in the first stage of the oxidation, including also (CHO)₂, which is a possible oxidation product, polymerize in great part, and that these polymerized aldehydes, together with unchanged oil, form the well-known elastic varnish—linoxyn.

M. HEIDELBERGER.

Coloring matter of cotton flowers. III. ARTHUR G. PERKIN. *J. Chem. Soc.* 109, 145-54 (1916); cf. C. A. 4, 1033; 7, 2385.—An attempt to ascertain if there is any chem. distinction not only between the Egyptian and ordinary Indian yellow cotton flower, *Gossypium herbaceum*, but also between these and the red, pink, and colorless petals of other varieties; also whether the red coloring matter in the red and yellow flowers is due to the red oxidation products of either gossypetin or gossypitrin. Red cotton flowers, *G. arboreum*, Linn.: The red alc. ext. of 1600 g. flowers was concd., dild. with hot H₂O, and the alc. evapd. off. After extn. with Et₂O the liq. was boiled with Pb(OAc)₂ soln. and the greenish brown ppt. decompd. with H₂S. Filtration of the maroon liquid and evapn. *in vacuo* for several days gave a red, semi-gelatinous product from which was isolated isoquercetin. Other flavone glucosides could not be detected, thus showing a marked difference from the yellow Egyptian flowers. The red, viscous mass obtained by concg. *in vacuo* the filtrate from the isoquercetin did not yield the typical color reactions of gossypitone after hydrolysis with boiling 1% H₂SO₄ and removal of quercetin by dissolving in C₆H₆N and pptg. with Et₂O, repeating the process, indicating that the color may be due rather to a true anthocyanin. Yellow flowers, *G. neglectum*: The concd. alc. ext., on long keeping, gradually gave a ppt., which, dissolved in hot H₂O, treated with Pb(OAc)₂, decompd. with H₂S, and concd. *in vacuo*, gave a semi-gelatinous mass, which, recrystd. first from dil. alc., then from boiling H₂O, yielded gossypitrin (A), m. 240-2°, whereas the (A) isolated from the Egyptian flowers (*loc. cit.*) m. 200-2°. It was found that by boiling the higher m. variety with acetone, finer needles with 1 H₂O were formed, and that these m. 200-2° whether anhydrous or not. This form is converted into the higher m. variety by boiling with H₂O. The mother liquors from the crude (A), on further evapn. *in vacuo*, gave a small amt. of a sol. glucoside which yielded quercetin on hydrolysis, while the final mother liquors contained a readily sol. quercetin glucoside, from which, by the methods described for the red flowers, was finally sepd. a small amt. of a red powder very similar to that isolated from the *G. arboreum*. The filtrate from the Pb ppt., treated with Pb(OH)OAc, gave a ppt. which yielded isoquercetin when decompd. as usual. The ordinary yellow Indian cotton flower, *G. herbaceum*, gave the same results as the *G. neglectum*, the surprising feature being the absence of quercimeritria, an important constituent of the Egyptian yellow flowers. The white and pink Indian

flowers yielded no definite results. Like gossypetin, (A) and $O:C_6H_4:O$ in alc., when gently warmed, yielded maroon needles of *gossypitrone*, $C_{21}H_{18}O_{11}$, gradually decomps. above 200° , m. about $255-9^\circ$, dyes Al-mordanted cotton green. Like the red cotton petals, it gives a greenish brown ppt. with $Pb(OAc)_2$. The ease with which it is reduced to (A) by SO_2 indicates that it is the quinone of (A). On wool the shades were identical with those produced by (A), thus showing the reverse properties of those of gossypetin and its quinone. Heated to boiling with 7% H_2SO_4 it is both hydrolyzed and reduced, the main product being apparently gossypetin; this is an important difference from the behavior of the red product obtained above from the red petals, indicating that the 2 are not identical.

M. HEIDELBERGER.

Non-aromatic diazonium salts. V. Diazo derivatives of aminotriazoles. GILBERT T. MORGAN AND JOSEPH REILLY. Dublin. *J. Chem. Soc.* 109, 155-60(1916).—Thiele and Manchot were the first to point out that the aminotriazoles form diazo salts capable of coupling with aromatic bases (*Ann.* 303, 41(1898)). 10 g. aminoguanidine carbonate were converted into the nitrate by evapg. dry on the H_2O bath with the calcd. amt. HNO_3 , then into the Ac deriv. by heating 24 hrs. under a reflux with 20 cc. H_2O and 10 cc. $HOAc$, adding H_2O or dil. $HOAc$ from time to time to keep the product in soln., and evapg. dry. The salt, taken up with H_2O , evapd. dry with 0.5 mol. Na_2CO_3 , extd. repeatedly with abs. alc., this distd., and the residue purified by extn. in a Soxhlet with $EtOAc$, gave quant. 5-amino-3-methyl-1,2,4-triazole (A), $N:CMe.N:C(NH_2).NH$. The diazonium salt obtained in dil. HCl decompd. rapidly,

even at 0° , yielding the 5-Cl deriv. In dil. HNO_3 the salt is much more stable and couples readily with alc. $\beta-C_{10}H_7OH$, the resulting 3-methyl-1,2,4-triazole-5-azo- β -naphthol forming dark orange-brown plates and needles, m. $213-5^\circ$, sol. in H_2SO_4 with a purple color, sol. in cold dil. KOH , probably due to the acidic NH in the triazole nucleus. The diazonium salt, in dil. HNO_3 , gives an almost quant. yield of 5-diazo-3-methyl-1,2,4-triazole chloraurate, prisms, stable at room temp., effervesces when slowly heated, explodes on heating rapidly to 100° , changes to a red substance in aq. soln. (A), diazotized in dil. HNO_3 with excess of $EtONO$, and evapd. dry at room temp. over KOH , gives 3-methyl-1,2,4-triazole-5-isodiazohydroxide, colorless crystals, stable at 100° , intumesces 120° , seps. from alc. as needles with 1 $EtOH$, does not couple with $\beta-C_{10}H_7OH$, but is converted into the normal diazo salt on dissolving in concd. H_2SO_4 or HNO_3 (2:1). 5-Amino-1,2,4-triazole (B) was prepd. similarly to the 3-Me deriv., using HCO_2H instead of $HOAc$. In dil. HCl the diazonium salt was very unstable, but was more stable, although less so than that from (A), when prepd. in dil. HNO_3 . 1,2,4-Triazole-5-azo- β -naphthol, orange crystals, m. $252-5^\circ$, sol. in H_2SO_4 with a bluish purple color, sol. in cold dil. aq. KOH . 1,2,4-Triazole-5-azo- β -naphthylamine, dark brown-red plates, m. $243-5^\circ$, gives a brown-yellow color with H_2SO_4 and dissolves in cold dil. aq. KOH . (B), diazotized with $NaNO_2$ in dil. H_2SO_4 , gives 5-diazo-1,2,4-triazole chloraurate, opaque crystals. A somewhat impure isodiazio deriv. was also prepd.

M. HEIDELBERGER.

Interaction of tetranitromethane and potassium ferrocyanide. FREDERICK D. CHATTAWAY AND JOHN M. HARRISON. Oxford. *J. Chem. Soc.* 109, 171-4(1916).—90 g. $K_4Fe(CN)_6$ in 300 cc. H_2O were shaken vigorously with 3 g. $C(NO_2)_4$ for 1 hr., the soln. becoming intensely yellow, changing to brown, and depositing crystals of K aci-trinitromethane, according to the equation $C(NO_2)_4 + 2K_4Fe(CN)_6 \longrightarrow C(NO_2)_3:NO.OK + KNO_3 + 2K_2Fe(CN)_6$. In order to det. the max. yield, the filtrate, now satd. with the salt, was shaken again with 10 g. $C(NO_2)_4$, the yield being 9.4 g. (theory, 9.6 g.). From the filtrate obtained after shaking with an excess of $C(NO_2)_4$ were obtained $K_2Fe(CN)_6$ and, on acidification, N_2O_4 . This is a much safer way of

prepg. the salt than that described by Macbeth (*C. A.* 7, 3973). $\text{BrC}(\text{NO}_2)_3$ reacts similarly with a satd. soln. of $\text{K}_4\text{Fe}(\text{CN})_6$, while Cl_3CNO_2 and Br_3CNO_2 do not react at all. The relative spaces occupied by the C atom and the NO_2 groups are such that only 3 of the latter can approach sufficiently near the center of attraction to receive the max. attractive force. A 4th group, if sufficiently large, would force the others away from the center of attraction, making it possible for 1 to be detached by a suitable reagent. If the spaces occupied by the first 3 groups are less, the 4th group will not have this effect, this being, apparently, the case with the last 2 substances.

M. HEIDELBERGER.

Preparation of diethylamine. WILLIAM E. GARNER AND DANIEL TYLER. Univ. Coll., London. *J. Chem. Soc.* 109, 174-5 (1916).—A modification of Hofmann's method. While H. could not sep. a mixt. of Et_2NH , Et_3NH , and Et_4N , G. and T. have found that practically pure Et_2NH may be fractionated from a mixt. of the 3. 8000 cc. alc. and 3000 g. EtBr were satd. with NH_3 several times during the day, the temp. gradually rising to 30° , and NH_4Br crystg. out. After 24 hrs. the soln. was sep'd from the salt, and the alc. and unchanged EtBr distd. off, adding H_2O and boiling to remove the last traces of alc. Conc'd. NaOH was then added and the amines distd. off. The alc. NH_3 - EtBr was used in the prepn. of a new lot. Using a 10-bulb column, there was no difficulty in segg. the amines. Yields, 10.9% Et_2NH , 17.9% Et_3NH , 19.1% Et_4N . About 80% of the Et_2NH (b. within 1°) can be obtained by 2 fractional distns. The crude Et_2NH fraction was worked up as follows: 500 g. (containing about 10% Et_3NH) were dissolved in 2500 cc. alc. and 1000 g. EtBr added, cooling with ice. After 24 hrs. 200 g. NH_4Br were added to fix any free amines present, and the soln. was treated as above. Yields, 38.7% Et_2NH , 30.1% Et_3NH , 17.3% Et_4N . As the Et_2NH can be again used, about 50% of this can be converted into Et_4N .

M. HEIDELBERGER.

Synthesis of ketoindopyranols. SOSALE G. SASTRY AND BROJENDRA N. GHOSH. Univ. Coll., London. *J. Chem. Soc.* 109, 175-80 (1916); cf. *C. A.* 10, 41.—An extension of previous work. 7 g. $\text{C}_6\text{H}_4(\text{CO})_2\text{CH}_3$ and 5 g. AcCH_2Ac did not condense in the presence of alkali, but dissolved in a little MeOH and treated with a rapid current of HCl for 4-5 hrs. the soln. reddens, and after 3 days crystals begin to sep. The yield is increased if the soln. is satd. with HCl from time to time and the ppt. collected after 7 days. The resulting 4'-keto-4-methylene-6-methyl-2,3-indenopyrane(1,4) hydrochloride (I) forms brown needles, m. 120° ; in alc. with aq. NaOAc , it gives the free base, brown

prisms, m. 182° , sol. in H_2SO_4 with a dark red color, insol. in cold NaOH , but sol. on warming with a purple color. Similarly in HOAc , BzCH_2Ac gave, after 36 hrs., 4'-keto-6-phenyl-4-methylene-2,3-indenopyrane(1,4) hydrochloride, brown prisms, m. $190-200^\circ$; in $\text{C}_6\text{H}_5\text{N}$, followed by H_2O , it gives the free base, brown prisms, m. 219° (decompn.). AcPhCHCN (cf. *C. A.* 10, 1031) gave, after 24 hrs., 4-imino-4'-keto-5-phenyl-6-methyl-2,3-indenopyrane(1,4) hydrochloride (II), dark red needles, m. 210° (decompn.); free base, brown prisms, m. 222° (decompn.), sol. in H_2SO_4 with a dark red color, in boiling NaOH with a red color and evoln. of NH_3 . (II), boiled 4-5 hrs. with 10% H_2SO_4 gives 4,4'-diketo-5-phenyl-6-methyl-2,3-indenopyrane, pale yellow needles, m. 236° , sol. in boiling dil. NaOH with a dark red color.

M. HEIDELBERGER.

Saponification of benzoylated cyanohydrins by acetic acid in the presence of metallic salts. J. ALOY AND CHARLES RABAUT. *Bull. soc. chim.* 19, 44-6 (1916); cf. *C. A.* 6, 1750; 7, 3115.— $\text{PhCH}(\text{OBz})\text{CN}$, $p\text{-HOC}_6\text{H}_4\text{CH}(\text{OBz})\text{CN}$ and $p\text{-MeOC}_6\text{H}_4\text{CH}$

$\text{CH}(\text{OBz})\text{CN}$ (A) in AcOH, when treated with Zn, gave rise to the corresponding amides. The amide of (A), $4\text{-MeOC}_6\text{H}_4\text{CH}(\text{OBz})\text{CONH}_2$, m. 155° . In the above reactions, ZnO or $\text{Zn}(\text{OAc})_2$ may be substituted for Zn. The reaction is best carried out under the following conditions: A mixt. of 4 g. of the cyanohydrin in 25 cc. 80% AcOH and 1 g. ZnO is gently heated for 1-2 hrs. The product is poured into 500 cc. H_2O and the pptd. amide crystd. from alc. Ordinarily the yields exceed 50%. HgO , Ag_2O , NiO , CoO and CuO may be used instead of ZnO; PbO , CdO , Al_2O_3 , Fe_2O_3 , Cr_2O_3 , ThO_2 , and the oxides of alkalis and alk. earths are inactive. MnO_2 shows slight activity. ZnSO_4 and CuSO_4 may replace ZnO, but CoCl_2 is inactive. Controls with AcOH and the cyanohydrins alone gave inappreciable yields. LOUIS E. WISE.

Alkaloids of the calabar bean. V. Action of phenyl isocyanate. Phenylic homologs of eserine and geneserine. MAX POLONOVSKI. *Bull. soc. chim.* 19, 46-59 (1916); cf. C. A. 10, 1165.—(Correction: Part IV of this series consisted solely of Polonovski's work. Nitzberg's name as joint author was due to an error in *Bull. soc. chim.*) Eseroline (A) in Et_2O in the presence of traces of Na reacted with PhNCO to form pheneserine (B) (eseroline phenylurethan), $\text{PhNHCO}_2(\text{C}_{18}\text{H}_{17}\text{N}_2)$, prisms, m. 150° , $\alpha_D -80^\circ$ (in abs. alc.), quite basic, decomp. when heated with $\text{Ba}(\text{OH})_2$ or NaOH into (A), CO_2 and PhNH_2 . (B) dissolves in aq. acids, forming salts whose solns. when evapd. to dryness leave varnishes. The salicylate of (B) cannot be crystd. The picrate, amorphous yellow powder, softens 80° , m. about 100° . The methiodide of (B), needles, m. 198° , $[\alpha]_D -92.8^\circ$ (n alc.). (As the elementary analyses of PhNCO , of (A) and of their condensation products give nearly identical C, H and N figures, P. has characterized derivs. by detg. the approx. amt. of CO_2 liberated by sapong. the condensation products with $\text{Ba}(\text{OH})_2$.) A mixt. of 1 g. (A) and 1.1 g. PhNCO and 20 cc. benzine, when heated in a sealed tube at 100° for 4 hrs., yielded dipheneserine, $\text{PhNHCONC}_{18}\text{H}_{18}\text{NOCONHPh}$ (C), microneedles from EtOH, m. 184° , $\alpha_D -244^\circ$ (in CHCl_3), insol. in NaOH. By treating (B) with PhNCO , (C) was also formed. A mixt. of 1 mol. (A) and 1 mol. PhNCO in anhydrous Et_2O , if filtered immediately after the formation of the first cryst. deposit, yielded eseroline phenylisocyanate (D), $(\text{C}_{18}\text{H}_{17}\text{N}_2\text{O})(\text{PhNCO})$, m. poorly $110-5^\circ$, which, when heated in benzine, yields a mixt. of (A), (B) and (C). A very similar mixt. was obtained when the Et_2O mother liquors formed in the synthesis of (D) were evapd. to dryness and heated with benzine, and when (A) was heated with an equimol. amt. of PhNCO . Geneseroline (E), reacting with PhNCO in Et_2O in the presence of traces of Na, yielded as the sole product, phenogeneserine (geneseroline phenylurethan), $(\text{C}_{18}\text{H}_{17}\text{ON}_2)\text{OCONHPh}$, m. 164° , α_D (in CHCl_3) -125.5° , readily converted into (B) when reduced with Zn in AcOH. Variations in the conditions of reaction between (E) and PhNCO gave rise to no further addition or condensation products. PhNCO when treated with an equimol. amt. of eserine (F) in Et_2O yielded only an oil. Condensation between (F) and PhNCO in benzine in the presence of Na carried out in a sealed tube at 100° gave rise to an amorphous substance and a small amt. of (B). Heated with 2 mols. PhNCO , (F) in the presence of traces of AcONa in a sealed tube yielded an addition product, $(\text{C}_{18}\text{H}_{17}\text{N}_2\text{O}_3) \cdot 2\text{PhNCO}$, non-cryst., m. about 100° , $\alpha_D -220^\circ$ (in benzine), yielding, when heated with NaOH, MeNH_2 , $(\text{PhNH})_2\text{CO}$ and (A). Eserethol and PhNCO , reacting in the presence of AcONa , yield an addition product, an oil with 2 mols PhNCO . Neither geneserine nor geneserethol give compds. with PhNCO . The striking analogies between the action of MeNCO and PhNCO are clearly shown by means of tables. LOUIS E. WISE.

Berberine. III. Azo derivatives of 1-R-dihydroberberine. MARTIN FREUND AND KARL FLEISCHER. Univ. Frankfurt. *Ann.* 411, 1-13 (1916); cf. C. A. 9, 2872. —1-R-Dihydroberberine (A) (but not berberine) contains a reactive H atom in position 4 which may be replaced by Me by the action of MeI. The present work shows

that this H may be replaced by other groups. While Na is without effect upon a C_6H_5 soln. of (A) yet it reacts with $PhN:NX$, the diazo group entering position 4. The $(PhN:N)_2SO_4$ from 9.3 g. $PhNH_2$, 19.5 g. concd. H_2SO_4 , 50 cc. 2N $NaNO_3$, and 150 g. ice is poured into an ice-cold soln. of 42.7 g. benzylidihydroberberine (B) in 300 cc. 50% AcOH and the intensely red soln. satd. with NH_3 . *Benzeneazo-4-[1-benzylidihydroberberine]* (C), seps. as a deep red ppt., dark red rhombic plates from $EtOH-CHCl_3$, m. 185° . *Hydrochloride*, yellow-brown tables, darken 140° , m. 146° (decompn.). *Sulfate*, yellowish red rectangular tables, m. 180° (decompn.). Both salts darken in the light. *Methiodide*, by heating 1.5 g. (C) and 2 cc. MeI 3 hrs. in a tube, deep red tables, m. 213° (decompn.). 1 g. (C), in 10 cc. AcOH and 5 cc. H_2O , treated with 2 g. Zn and heated 4 min., gave (B). The same mixt., warmed 1.75 hrs., gave a mixt. of (B) and benzyltetrahydroberberine (D). 10 g. (C), in 400 cc. $EtOH$, 200 cc. H_2O and 55 cc. 30% H_2SO_4 , reduced with a Pb cathode with 10-13 amp. at $30-40^\circ$, and adding during the reduction (4.5 hrs.) 20 cc. 30% acid, gave 8 g. base from which 3.6 g. (D) and 1.4 g. pseudo base were isolated. The fact that an NH_3 compd. is not obtained indicates the probable presence of a conjugated double bond, $-N:N-C:C-$, which upon reduction gives $-NH-N:C-CH-$. Upon hydrolysis

this yields the 4-HO compd., which is then reduced to (B) or (D). *Benzeneazo-4-[1-ethylidihydroberberine]* was prepd. by mixing 3.7 g. 1-ethylidihydroberberine in 40 cc. 50% AcOH and 30 cc. cold diazo soln. (from 0.93 g. $PhNH_2$) and adding 20 g. $AcONa$, deep red rectangular columns with a Cu luster, m. 216° . *p-Benzene-sulfo-4-[1-benzylidihydroberberine]*, by treating the diazo soln. from 4.2 g. $p-H_2NC_6H_4SO_3H$ with 8.5 g. (B) in 80 cc. 50% AcOH and liberating the base with dil. H_2SO_4 , reddish yellow spears from hot AcOH, decomp. 274° ; it is very sensitive towards light. α -*Naphthaleneazo-4-[1-benzylidihydroberberine]*, obtained by treating the diazo soln. from 2.9 g. $\alpha-H_2NC_{10}H_7$ with 8.5 g. (B) and satg. with NH_3 , dark brown needles with a greenish luster from $EtOH-CHCl_3$, m. 218° . In the same way β -*naphthaleneazo-4-[1-benzylidihydroberberine]* was obtained as a dark red amorphous powder; *sulfate*, reddish yellow needles from dil. alc., decomp. 190° . *Biphenyl-p,p'-di[azo-4-(1-benzylidihydroberberine)]*, prepd. from 1.8 g. benzidine, and 8.5 g. (B), brownish black, amorphous powder from $EtOH-CHCl_3$, sinters 180° , m. over 200° . The AcOH soln. is bluish red. *p-Arsenobenzeneazo-4-[1-benzylidihydroberberine]*, obtained from the diazo soln. from 5.6 g. atoxyl and 8.5 g. (B), reddish yellow powder from dil. alc., does not m. 275° . The alk. soln. is deep red. *Sodium salt*, deep red cryst. powder, sol. in H_2O with neutral reaction and red color. 4.3 g. (B) and 2.7 g. Michler's ketone heated with 10 cc. $POCl_3$ for 5 hrs. at 100° , gave a dark amorphous powder, sol. in $EtOH$ or $CHCl_3$ with violet-red color, in dil. HCl with emerald-green and in dil. AcOH with brownish red color.

C. J. WEST.

Indandione. V. Constitution of mellophanic and prehnitic acids. MARTIN FREUND, KARL FLEISCHER AND MAX PRAETORIUS. Univ. Frankfurt. *Ann.* 411, 14-38(1916); cf. C. A. 9, 2874.—Baeyer's formulas for mellophanic and prehnitic acids, 1,2,3,4- and 1,2,3,5- $C_6H_2(CO_2H)_4$, which were questioned by Jacobsen (*Ber.* 17, 2517(1884)) have been confirmed by Bamford and Simonsen (C. A. 5, 479). In the present work these acids have been prepd. from indandiones and Baeyer's formulas further confirmed. *Benzo-4,7-dimethyl-2-diethylindan-1,3-dione* (I) is prepd. by treating a soln. of 21.2 g. $p-C_6H_4Me_2$ and 39.2 g. $Et_2C(COCl)_2$ in 100 cc. CS_2 with 50-60 g. $AlCl_3$ in 5 portions, and warming on the H_2O bath until evolution of HCl ceases; decompd. in the usual way, the resulting oil is freed from a small amt. of acid-reacting liquid (fatty acid odor) by heating to 200° , and then distd. at $164-5^\circ$ under 14 mm.; 6-sided leaflets from dil. alc., m. $51-2^\circ$. 23 g. (I), when heated with 60 cc. 50% KOH

until a K salt seps. and the product taken up in H_2O and acidified, gives 20 g. 2,5-dimethyl-6-diethylacetylbenzoic acid (A), quadratic leaflets from ligroin, m. 150° . It causes coughing and sneezing. Conc'd. H_2SO_4 gives a deep yellow soln. with a yellowish green fluorescence. It is not esterified with MeOH and HCl, does not react with $PhNHNH_2$, and does not form a lactone when heated above its m. p. Oxidized with HNO_3 by heating 12.4 g. (A) with 120 g. HNO_3 (d. 1.4) for 2 hrs. on a H_2O bath, 3,6-dimethylbenzene-1,2-dicarboxylic anhydride (B) is formed, needles from abs. alc., m. 143° , on sublimation, m. 145.5° . Heated with 10% NaOH until soln. results, 3,6-dimethylbenzene-1,2-dicarboxylic acid (C) is formed, prismatic spears, m. 145° (Gucci and Grassi-Cristaldi, *Jahrb.*, [2] 1891, 2156, give 96°). Attempts to cryst. (C) always gave a mixt. of anhydride and acid. Mellophanic acid (D) was obtained (1), by oxidation of 5 g. (I) with 5 cc. fuming HNO_3 and 2.5 cc. H_2O in a tube at 140° for 7.5 hrs.; (2),

(I)

(II)

by oxidizing 2 g. (A) with 2 cc. fuming HNO_3 and 1 cc. H_2O in a tube 7-8 hrs. at 140° , or (3) by oxidizing 2 g. (B) with 2 cc. fuming HNO_3 and 1 cc. H_2O 7-8 hrs. at 140° . The acid was identical with that described by Baeyer. (D), heated to $245-50^\circ$, gives the dianhydride (cf. *Ann.* 166, 344), rhomboid crystals from ligroin and C_6H_6 , sinters 185° , m. $193-6^\circ$. Upon standing for some time in closed vessels, the m. p. changes ($175-220^\circ$); the substance is then insol. in ligroin- C_6H_6 , but is sol. in H_2O . 20 g. (I), boiled with 140 g. amalgamated Zn and 500 cc. HCl (d. 1.19), and then distd. with steam, gives 2-diethyl-4,7-dimethylhydrindene (II), b_{11} $140-1^\circ$, d. 0.923, n 1.52592. Benzo-4,6-dimethyl-2-diethylindan-1,3-dione (D), prepd. from m - $C_6H_4Me_2$, $Et_3C(COCl)_2$ and $AlCl_3$ as above, yellow aromatic oil, b_{11} $168-71^\circ$, d. 1.055. 3,5-Dimethyl-2-diethylacetylbenzoic acid (E), 6-sided flat plates from ligroin, sinters, 121° , m. $126-7^\circ$. The soln. in conc'd. H_2SO_4 is a pale yellow. This compd. also causes sneezing and coughing. It does not form a lactone and does not react with $PhNHNH_2$. Methyl ester, m. $69-71^\circ$. 3,5-Dimethylbenzene-1,2-dicarboxylic acid (F), prepd. by oxidation of 4 g. (E) in 30 cc. AcOH with 8 cc. HNO_3 (d. 1.4) by heating 2 hrs. on the H_2O bath, and isolated partly as the anhydride, m. $113-6^\circ$ (Noyes, *Am. Chem. J.* 20, 810(1898)), and partly as the free acid, needles from H_2O , m. 181° , forming the anhydride. (F) was also obtained by heating 2 g. (E) with 2 cc. HNO_3 and 1 cc. H_2O 8 hrs. at 140° . Prehnitic acid (G) was obtained by the oxidation of (D) with HNO_3 in a sealed tube at $145-50^\circ$ for 8 hrs., or of the anhydride of (F); it was identical with Baeyer's acid. Upon reduction of (D) with Zn and HCl, 4,6-dimethyl-2-diethylhydrindene was obtained in one expt., b. $260-70^\circ$. Other expts. gave a product b_{11} $136-40^\circ$, which analyzes for $C_{14}H_{16}$; this is probably formed by the opening of the 5-membered ring with the addition of 2 H. From the results of this work it follows that the phthalidetricarboxylic acid of Döbner's (*Ann.* 311, 135(1900)) is a deriv. of (G) and has one of the two formulas

C. J. Wessr.

Oxonium compounds. II. Oxonium compounds with reactive methylene groups. W. BORSCHÉ AND K. WUNDER. Univ. Göttingen. *Ann.* **411**, 38–72 (1916); cf. C. A. 7, 782.—The hypothesis of an active methylene group in the pyrylium salts is further extended to a number of similar compds. The reactions used were the condensation with an aldehyde, the product being isolated as the chloride or the FeCl_3 salt, and the action of HNO_3 . The latter has not proved satisfactory. 4-[5-Methylsalicylal]-1-methyl-R-hexan-3-one (I), prepd. from 27 g. 2,5-(HO) $\text{MeC}_6\text{H}_3\text{CHO}$ and 23 g. *d-m*-methyl-

R-hexanone, yellow needles from MeOH, compact prisms from C_6H_6 , m. 142° . Dissolved in 8 parts AcOH-HCl (satd.) and the red soln. treated with FeCl_3 , 3,13-dimethyl-1,2,3,4-tetrahydroxanthylum chloride-ferric chloride (A) seps. as long, light red needles, m. $104-5^\circ$. 4-[5-Chlorosalicylal]-1-methyl-R-hexan-3-one (B), from 31.4 g. 2,5-(HO) $\text{ClC}_6\text{H}_3\text{CHO}$ and 23 g. *d-m*-methyl-R-hexanone in 200 cc. alc. and 26 g. NaOH in 130 cc. H_2O , allowing the mixt. to stand 1 week, pptg. the neutral soln. with CO_2 and crystg. from MeOH or C_6H_6 , compact, yellow needles, m. 153° . 3-Methyl-13-chloro-1,2,3,4-tetrahydroxanthylum chloride-ferric chloride (C), long needles with green luster, m. $110-11^\circ$. 10-Methyl-12-hydroxy-1,2,3,4-tetrahydroxanthylum chloride (D), prepd. by treating a soln. of 11 g. *m*- $\text{C}_6\text{H}_4(\text{OH})_2$ and 14 g. α -acetyl-R-hexanone (E) in 14 cc. AcOH with dry HCl gas, and recrystg. the product from a mixt. of 70 parts alc., 20 parts H_2O and 10 parts concd. HCl, greenish yellow needles, m. $167-9^\circ$ (decompn.); yield, 75%. Ferric chloride salt, $3\text{C}_{14}\text{H}_{11}\text{O}_7\text{Cl}_2\cdot 2\text{FeCl}_3$, yellow needles, m. $161-2^\circ$. Picrate, $\text{C}_{14}\text{H}_{11}\text{O}_7\cdot \text{C}_6\text{H}_3\text{O}_7\text{N}_3$, brownish yellow iridescent crystals, darken at 155° , decomp. 170° . AcONa ppts. the carbinol from an alc. soln. of the chloride as bright red amorphous flakes. The pyrylium chlorides from trihydroxyphenols proved to be too insol. in AcOH-HCl to be used for condensations. 10-Methyl-11,12-dihydroxy-1,2,3,4-tetrahydroxanthylum chloride, from 5.2 g. pyrogallol and 5.6 g. (E) in 10 cc. AcOH and HCl gas, deep red needles, m. $250-1^\circ$. 10-Methyl-12,13-dihydroxy-1,2,3,4-tetrahydroxanthylum chloride, from 1.8 g. hydroxyquinol and 2 g. (E) in 6 cc. AcOH, fine, yellow needles, sinter 235° , m. 250° ; the alc. soln. has a green fluorescence. 10-Methyl-12,14-dihydroxy-1,2,3,4-tetrahydroxanthylum chloride, from 1.8 g. phloroglucinol and 2 g. (E) in 8 cc. AcOH, yellow crystals, m. $258-60^\circ$, quite insol. in AcOH-HCl- H_2O . 3,10-Dimethyl-12-hydroxy-1,2,3,4-tetrahydroxanthylum chloride, from 11 g. resorcinol and 15.4 g. *d*-1-methyl-4-acetyl-R-hexan-3-one in 18 cc. AcOH by satg. with HCl gas, allowing the mixt. to stand 1–2 days and completely pptg. with 40 cc. alc. and 40 cc. Et_2O , yellow needles, reddened at 130° , m. $180-2^\circ$. When dissolved in alc. and treated with AcONa, the xanthidrol is obtained as a light red amorphous powder, m. $150-5^\circ$; it analyzes for an anhydride, the formation of which may have taken place either in the pptn. or in the drying. In dil. NaOH it gives a light yellow soln., from which AcOH ppts. the xanthidrol. Boiling with 25% KOH does not decomp. the carbinol. Chloride-ferric chloride, $3\text{C}_{14}\text{H}_{11}\text{O}_7\text{Cl}_2\cdot 2\text{FeCl}_3$, yellow leaflets, m. 155° . 3,10-Dimethyl-12-methoxy-1,2,3,4-tetrahydroxanthylum chloride-ferric chloride, from 2.1 g. $\text{MeOC}_6\text{H}_4\text{OH}$ and 2.5 g. acetyl-*m*-methyl-R-hexanone in 5 g. AcOH (the reaction requires several weeks), fine, yellow needles, m. $101-2^\circ$. This has the normal compn. Condensation products with aldehydes. α -Methylbenzopyrylium chloride. α -Methylenedioxystrylbenzopyrylium chloride (II) was prepd. by treating 1.62 g.

o-hydroxybenzalacetone in 9 cc. AcOH with 9 cc. satd. AcOH-HCl and after 1 hr. with 1.48 g. piperonal; the soln. becomes a deep bluish red at once and a dark red powder seps., decomp. 195–200°. *Ferric chloride salt*, dark brown powder, m. 208°. *3-Methyl-1,2,3,4-tetrahydroxanthylum chloride*. *3-Methyl-4-benzal-1,2,3,4-tetrahydroxanthylum chloride-ferric chloride*, from 2.16 g. salicylal-*m*-methyl-*R*-hexanone and 1.1 g. BzH in 21 cc. AcOH-HCl and adding FeCl₃ after 2 days, flat, orange needles, m. 129–30°. *4-Cinnamal chloride-ferric chloride*, using 1.4 g. PhCH:CHCHO, deep bluish violet leaflets with Cu luster, m. 203–4° (decompn.). *4-p-Hydroxybenzal chloride*, from 1.2 g. *p*-HOC₆H₄CHO, bluish green needles, decomp. 127–8°. Recrystd. from AcOH-HCl it loses 0.5 mol. HCl. *Ferric chloride salt*, dark red crystals with golden luster, m. 153–4°. *4-p-Methoxybenzal chloride-ferric chloride*, from 1.4 g. MeOC₆H₄CHO, dark red needles with steel-blue luster, decomp. 170°, m. 177°. *4-Piperonylidene chloride-ferric chloride*, dark, flat needles with metallic green reflecting surfaces, giving a violet powder, m. 166–7°. *4-o,p-Dihydroxybenzal chloride*, dark red crystals with a metallic luster, decomp. 188–9°. *4-p-Nitrobenzal chloride-ferric chloride*, fine, orange-yellow needles, m. 144.5°. *3,13-Dimethyl-1,2,3,4-tetrahydroxanthylum chloride*. *3,13-Dimethyl-4-[5-methyl-2-hydroxybenzal]-1,2,3,4-tetrahydroxanthylum chloride*, prepd. by dissolving 2.3 g. (I) in 18 cc. AcOH-HCl and after 0.5 hr. adding 1.3 g. 2,5-(HO)MeC₆H₃CHO, dark red needles, m. 154°. *Ferric chloride salt*, nearly black needles with dark green schimmer, m. 179–80°. *4-p-Hydroxybenzal chloride*, golden green crystals, m. 175°. *4-Piperonylidene chloride-ferric chloride*, dark red needles with green metallic luster, m. 156–7°. The chloride (not analyzed), bluish red, m. 174–5°. *3-Methyl-13-chloro-1,2,3,4-tetrahydroxanthylum chloride*. *3-Methyl-4-benzal-13-chloro-1,2,3,4-tetrahydroxanthylum chloride-ferric chloride*, from 2.5 g. (B) and 1 g. BzH, brown crystals with green surface reflex, m. 140°. *5-Chlorosalicylal chloride*, using 1.56 g. 2,5-(HO)ClC₆H₃CHO, deep red, decomp. 150°. *4-Piperonylidene chloride-ferric chloride*, greenish golden crystals, giving a dark violet powder, decomp. 160°. *2,4-Dimethyl-9-hydroxypyrylium chloride*. *2,0-Hydroxystyryl-4-methyl-9-hydroxypyrylium chloride*, prepd. from 2.3 g. chloride and 1.22 g. HOC₆H₄CHO, red crystals, very insol. in boiling AcOH, decomp. 189°. *2-Methylenedioxystryryl chloride*, dark red, m. 215°. *Ferric chloride salt*, dark brown ppt., very insol. in AcOH, decomp. 190°. *2,4-Dihydroxystyryl chloride*, from 1.3 g. *o,p*-(HO)₂C₆H₃CHO, powder with metallic luster, m. 232°. *10-Methyl-4-p-hydroxybenzal-12-hydroxy-1,2,3,4-tetrahydroxanthylum chloride*, dark red-brown crystals, decomp. 205–6°. *3,10-Dimethyl-4-salicylal-12-hydroxy-1,2,3,4-tetrahydroxanthylum chloride*, bright red powder, m. 247–8°. *3,10-Dimethyl-4-[2,4-dihydroxybenzal]-12-hydroxy-1,2,3,4-tetrahydroxanthylum chloride*, obtained with 0.5 mol. H₂O if the components are dissolved in AcOH and the soln. satd. with HCl, dark red powder, decomp. 210–11°. But if the aldehyde is added after the AcOH is satd. with HCl, the compd. is obtained with 1.5 H₂O, black crystals, decomp. 239°. *3-Methyl-4-hydroximinio-1,2,3,4-tetrahydroxanthylum chloride*, prepd. by treating 10.8 g. salicylal-*m*-methyl-*R*-hexanone in 85 cc. AcOH-HCl with 7.5 g. iso-AmNO₂ and 22.5 cc. AcOH with cooling and recrystg. the product which seps. after 2 hrs. from 100 cc. AcOH, light yellow needles, color at 125°, explode at 194–5°. The dry substance m. 215–20°. *Ferric chloride salt*, dark yellow, thin prisms, very sol. in AcOH and Et₂O, sinters 100°, m. 120°. H₂O ppts. the carbinol (III) from a 10% soln. of the chloride in AcOH as reddish white amorphous flakes, which can be filtered if 10 g. AcONa are added for each 10 g. of chloride, m. 120°. Upon drying it loses 0.5 mol. H₂O, and then m. over 200°. With AcOH-HCl it gives the chloride. 6.1 g. of the dried carbinol, in 61 g. C₆H₅N and treated with 8–10 g. BzCl, gives *α*-methyl-*γ*-coumarinobutyronitrile (IV), isolated by pouring the mixt. into AcOH, washing the ppt. with Na₂CO₃ and crystg. from dil. alc., needles, m. 116°. Sapond. by heating

1 g. (IV) with 6 cc. 5-N HCl in a sealed tube 3 hrs. at 150°, the acid is obtained as needles, m. 141-2°. 3,13-Dimethyl-4-hydroximino-1,2,3,4-tetrahydroxanthylum chloride, $C_{14}H_{18}O_2ClN \cdot 2H_2O$, yellow needles, m. 204-5°, after drying, 218-20°. Ferric chloride salt, compact, yellow-brown needles, decomp. 165°. α -Methyl- γ^a -5-methylcoumarino-butyronitrile, from 5.2 g. carbinol, 52 g. C_4H_5N and 6 g. $BzCl$, needles, m. 105-6°. Acid, crystal powder from $MeOH-H_2O$, m. 142-3°. C. J. WEST.

Photochemical syntheses of indole derivatives. PAUL PFEIFFER, S. BRAUDE, R. FRITSCH, W. HALBERSTADT, G. KIRCHHOFF, J. KLÄBER AND P. WITTKOP. Univ. Zürich. *Ann.* 411, 72-158(1916); cf. *C. A.* 6, 2736.—*o*-Nitrostilbene chlorides, monochlorostilbenes or tolanes, exposed to the action of light in concd. C_4H_5N solns., are rearranged into isatogens with a yield of about 60%. In some cases of the tolanes the C_4H_5N soln. rearranges without light in a few hrs. at room temp. Only those compds. which contain the *o*- O_2N group will rearrange. The proof of the constitution of the reaction products follows from the reaction of Zn and AcOH, by which phenylindoxyls are formed, and the by reaction with NH_2OH , in which 2 isomeric isatogen monoximes are formed, a *C*- and an *N*-oxime. The isatogens are typical quinones, forming a new class of *m*-quinoid compds., in which the group $N:O$ plays the role of a CO group. These compds. are similar to those described by Baeyer (*Ber.* 13, 2258) and the new constitution is applied to them and the mechanism of their formation is cleared up. The following system of numbering the isatogens is used:

Phenylisatogen and monosubstituted compds. 2-Nitrostilbene chloride (A), $o-O_2NC_6H_4CHClCHClPh$, prepd. by satg. 5 g. $o-O_2NC_6H_4CH:CHPh$ in 30-40 cc. boiling CS_2 with Cl and recrystg. the yellowish product from alc., pale yellow needles, m. 71-117°. Fractional crystn. from MeOH seps. the product into an α -chloride, small compact yellow transparent crystals, m. 122°, and the β -chloride, compact, rhombic transparent crystals, m. 76-9°. 2-Nitrotolane (B) was prepd. by boiling 1.2 g. (A) in alc. with 1.7 g. NaOH in 15 cc. alc. and 15 cc. H_2O 0.5 hr., pouring into H_2O , acidifying and extg. with Et_2O , yellow prismatic needles or tables from hot MeOH, m. 50-2°. Concd. H_2SO_4 gives a deep violet color. Phenylisatogen (C), formed when 1.3 g. (A) in 8 cc. pure C_4H_5N are allowed to stand in the sunlight for several days, or by heating (B) in C_4H_5N several hrs. (also by the action of light), deep orange-red leaflets from hot MeOH, m. 186-7°. 0.5 g. (C) and 1 g. $NH_2OH \cdot HCl$, heated in alc. for 6-12 hrs. on a H_2O bath, gave 0.5 g. oxime, which is sepd. by crystn. from a little glacial AcOH. *C*-Oxime, seps. first, yellow-orange, glistening leaflets, m. 236°, identical with the oxime from *N*-hydroxyphenylindole (Angeli and Angelico, *Rend. accad. Lincei* [5] 15, II, 761(1907)). *N*-Oxime, light yellow prismatic crystals, m. 167-8°. 2-Nitrophenylisatogen (D) is formed from 2,4-dinitrotolane by heating its C_4H_5N soln. a few min. or in 3-4 hrs. at room temp. either in the dark or light. A $C_4H_9Me_3$ soln. is not changed by heating but if a few drops of C_4H_5N are added the soln. changes color in a few min. 2 g. (D) gave 1.2-1.5 g. *N*-oxime and 0.5-0.8 g. *C*-oxime. The *N*-oxime is insol. in NH_4OH (sepn. from the *C*-oxime); flat, yellow needles from AcOH, which contain 2 mols. AcOH; this is lost in the air and the product then m. 183°. Acetyl derivative, fine, light yellow needles from hot alc., m. 136-7°. The NH_4OH ext., acidified with HCl, ppts. the *C*-oxime, deep orange-red leaflets from

AcOH upon slow crystn., orange-yellow leaflets if quickly crystd., m. 250°. *Acetyl derivative*, orange-red leaflets, m. 226°. *2,6-Dinitrostilbene (E)*, m. 114°, not 86° (*Ber.* 39, 1306). *2,6-Dinitrostilbene α -chloride (F)*, prepd. by satg. a suspension of 10 g. (E) in 50 cc. CS₂ with dry Cl gas, yellowish tables from AcOH, m. 204-5° (decompn.). *β -Chloride*, from (E) and Cl gas in CHCl₃, transparent tables from AcOH, m. 161°. A mixt. of the 2 m. 143-6°. *2,6-Dinitrostilbene bromide (G)*, prepd. by allowing 20 g. (E) in 60 cc. CHCl₃ to stand with an excess of Br for 3 days, compact wine-yellow tables, m. 146-7°. A small amt. of a second bromide is obtained, m. 198°. 5 g. (F), heated 7 hrs. with 15 g. C₆H₅N at 150°, gives *2,6-dinitro- μ -chlorostilbene*, PhCH:CClC₆H₄(NO₂)₂, light yellow needles or prisms, m. 100-1°. *2,6-Dinitro- μ -bromostilbene*, prepd. by warming 10 g. (G) and 60 g. C₆H₅N 3 days on the H₂O bath, yellow transparent rhomboids, m. 110-1°. *4-Nitrophenylisatogen*, by the action of light upon (F) in C₆H₅N for several weeks, red leaflets, m. 194°. *2'-Nitrophenylisatogen*, yellowish orange tables, m. 202-3°. *2-Cyanophenylisatogen (H)*, by the action of light upon 4-cyano-2-nitro- μ -chlorostilbene, yellow-orange leaflets, m. 227°. *N-Oxime*, small yellow leaflets from alc., m. 212-3°, insol. in 12% NH₄OH (sepn. from the C-oxime). Upon reduction with Zn and AcOH it yields 2-cyanophenylindoxyl. *Acetyl derivative*, fine rose-colored needles, m. 151-1.5°. Since upon reduction it

yields 2-cyanophenylindoxyl the acetate must have the formula NCC_6H_4 

C-Oxime, yellow-orange leaflets from alc., m. 246°. *2-Cyanophenylindoxyl (I)*, formed by the reduction of (H) with Zn and AcOH, Ag-gray needles from dil. AcOH, containing 1 mol. H₂O, m. 215°. *Acetyl derivative*, needles, m. 190-1°. *Quinhydrone of 2-cyanophenylisatogen and 2-cyanophenylindoxyl*, prepd. by slowly cooling a soln. of 3 g. (I) and 0.7 g. (H) in 40 cc. AcOH, black glistening needles, m. 185-6° (decompn.). C₆H₅N gives a brownish yellow soln. Et₂O decomp. it, (I) crystg. out. *2-Carboxymethylphenylisatogen*, orange leaf-like needles from MeOH, m. 132-3°. *4-Carboxyethyl-2-nitrostilbene chloride (J)*, prepd. by satg. an alc. soln. of the corresponding nitrile with HCl, small crystals from alc., m. 88.5°. *2-Carboxyethylphenylisatogen* may be prepd. from (J), by esterifying the corresponding acid, or from (H), orange needles, m. 138°. *N-Oxime*, fine, nearly colorless needles, m. 191° (decompn.). *Acetyl derivative*, fine needles, m. 134°. *2-Carboxyethylphenylindoxyl*, prepd. by reducing the oxime in boiling alc. and HCl or in AcOH with Zn, small, yellowish leaflets, m. 183-8° (decompn.). *Acetyl derivative*, glistening leaflets or needles, m. 187-90°. *2-Nitro- μ -chlorostilbene-4-carboxylic acid* is best prepd. by sapon. the ester with dil. alc. Na₂CO₃. Treated in C₆H₅N soln. with direct sunlight, *phenylisatogen-2-carboxylic acid* is formed, orange powder, m. 231-3°. *Pyridine salt*, red-orange needles, m. 150-1°. The C₆H₅N is lost at 80-100°. *Acetic acid compound*, orange-red transparent prisms, forming an orange powder in the air. *Propionic acid compound*, orange-yellow powder, gradually changing into orange-red transparent needles; they are stable in the air for only a few hrs. *Disubstituted phenylisatogens*: *2,4,3'-Trinitrostilbene (K)*, obtained by warming 27 g. 2,4-(O₂N)₂C₆H₃Me, 26 g. m-O₂NC₆H₄CHO and 30 drops piperidine at 185° 2 hrs., yellow needles from AcOH and then C₆H₅N, m. 182-3°. *2,4,3'-Trinitrostilbene chloride (L)*, from (K) and Cl in CHCl₃, pale yellow transparent prisms, giving a white powder, m. 168°. *Bromide*, by treating finely divided (K) with Br vapors for 14 days, compact, transparent light yellow cryst. powder, m. 190-1°. *2,4,3'-Trinitro- μ -chlorostilbene*, by boiling (L) in C₆H₅N for 4 days, light yellow needles, m. 164°. *2,3'-Dinitrophenylisatogen*, orange needles, m. 234°. *2,4-Dinitro-4'-methylstilbene*, prepd. by heating 15 g. 2,4-(O₂N)₂C₆H₃Me and 10 g. p-MeC₆H₄CHO with 15-20 drops piperidine at 165-70° for 0.25 hr., yellow leaflets from AcOH or alc., sinter

187°, m. 197°. Yield, 17 g. *2,4-Dinitro-4'-methylstilbene α-chloride*, sepd. by its greater soly. in AcOH, slightly yellow short prismatic needles, m. 167–7.5°. *β-Chloride*, asbestos-like needles, m. 155°. *2,4-Dinitro-4'-methyl-μ-chlorostilbene*, by heating 4 g. crude chloride and 20–25 cc. C_6H_5N 12 hrs., fine yellow tables, m. 136°. Yield, 3 g. *2-Nitro-4'-methylphenylisatogen*, violet-red leaflets, m. 212°. *2,4-Dinitro-4'-methoxystilbene*, obtained in 67% yield by heating 50 g. $MeOC_6H_4CHO$ and 68 g. $2,4-(O_2N)_2C_6H_3Me$ with 75 drops piperidine at 180° until the mass turns brown, then at 150° for 2 hrs., orange-red, compact crystals with bluish reflecting faces, m. 163°. *Dichloride*, best prepd. by passing Cl into a soln. of the stilbene until the color changes from orange to light yellow and then evapg. as rapidly as possible. Longer treatment with Cl gives products with Cl in the nucleus. *2-Nitro-4'-methoxyphenylisatogen*, small, brown-violet leaflets from AcOH or $PhCO_2Et$, m. 248°. *2,4-Dinitro-4'-acetoxystilbene (M)*, obtained by warming a mixt. of 10 g. $p-HOC_6H_4CHO$ and 15 g. $2,4-(O_2N)_2C_6H_3Me$ with 10 drops piperidine 1.5 hrs. at 155° (temp. of bath), adding a slight excess Ac_2O and warming 2 hrs. on the H_2O bath, pure yellow needles, m. 148°; yield, 15 g. Unless care is taken, a resin is formed. *2,4-Dinitro-4'-acetoxystilbene α-chloride*, sepd. by its insoly. in alc., needles, m. 158°. The *β-chloride*, m. 125–30°, was probably not pure. *2-Nitro-4'-acetoxystilbene (O)*, orange leaflets, m. 235°. *2,4-Dinitro-4'-hydroxystilbene (N)*, prepd. by heating 1 g. $p-HOC_6H_4CHO$, 1.5 g. $2,4-(O_2N)_2C_6H_3Me$ and 3 drops piperidine 3 hrs. at 160° or better by sapon. 10 g. (M) with 300 cc. satd. $MeOH-K_2CO_3$, pouring the K salt into H_2O and acidifying with HCl, orange leaflets from H_2O or deep red small leaflets with blue surfaces from PhMe, m. 162°. Crystd. from dil. alc., the red crystals turn yellow; these become red again when crystd. from PhMe. The yellow alc. soln. becomes a deep violet-red when treated with NaOH. *2,4-Dinitro-4'-methylethylacetoxystilbene*, $2,4-(O_2N)_2C_6H_3CH:CHC_6H_4OCOCHMeEt$, by heating 10 g. (N) with 8 g. $MeEtCHCOCl$ at 100°, citron-yellow needles from alc., opalescent yellow leaflets from CCl_4 , m. 123°. The chloride was an oil, which would not cryst. *2-Nitro-4'-methylethylacetoxystilbene*, red leaflets from AcOH, m. 216°. $MeOH-Na_2CO_3$ gives a deep green soln., from which HCl ppts. a violet substance, sol. in dil. NH_4OH with a green color. *2,4-Dinitro-4'-benzoxystilbene*, yellow needles from AcOH, m. 170°. *2-Nitro-4'-benzoxystilbene*, red leaflets from C_6H_5Me , m. 252°. *2-Nitro-4'-hydroxyphenylisatogen*, obtained by sapon. of (O) with $MeOH-K_2CO_3$, deep violet leaflets, m. 235–6°. Dil. NH_4OH and Na_2CO_3 give a deep green soln. from which HCl ppts. the unchanged isatogen. Aq. KOH gives a greenish yellow soln., quickly changing to yellow, due to some decompn. HCl does not give a violet ppt. with this soln. *2,4-Dinitro-μ-chlorostilbene-4'-sulfonic acid (P)*, prepd. by warming 5 g. $2,4-(O_2N)_2C_6H_3CCl:CHPh$ in a mixt. of 27 g. concd. and 3 cc. 30% fuming H_2SO_4 for 0.25 hr. at 100°, and filtering into ice and HCl, light yellow crystals, with 1 mol. H_2O , from H_2O , which do not m. Yield, 2.9 g. *2-Nitrophenylisatogen-4'-sulfonic acid*, by the action of sunlight upon 2 g. (P) in a mixt. of 40 cc. H_2O and 10 cc. C_6H_5N for 0.5 hr., red leaflets from 60% aq. C_6H_5N ; yield, 1.4 g. The compd. contains 1 mol. C_6H_5N which is lost at 120°. *4-Cyano-2-nitro-4'-methylstilbene*, by heating a mixt. of 25 g. $2,4-O_2N(NC)C_6H_3Me$, 18 g. $p-MeC_6H_4CHO$ and 20–25 drops piperidine 1.5 hrs. at 160°, flat, yellow needles, m. 170°; yield, 28 g. *4-Carboxyethyl-2-nitro-4'-methylstilbene*, by sapon. the nitrile in EtOH with HCl, long, yellow needles, m. 99–100°. *4-Cyano-2-nitro-4'-methylstilbene chloride*, sepd. by crystn. from AcOH into the *α-chloride*, transparent prismatic needles, m. 175–6°, and the *β-chloride*, asbestos-like needles, m. 130–1° (more sol.). The principal product is the *α-chloride*. *4-Cyano-2-nitro-4'-methyl-μ-chlorostilbene*, by boiling the chloride in C_6H_5N 2 days, yellow leaflets or tables, m. 133–4°. *2-Cyano-4'-methylphenylisatogen*, red leaflets, m. 249°, from AcOH. *4-Cyano-2-nitro-4'-methoxystilbene*, prepd. by heat-

ing a mixt. of 8 g. 2,4-O₂N(NC) 7.2 g. *p*-MeOC₆H₄Me and several drops piperidine 1 to 1.5 hrs. at 140–50°, m. 157–8°; it occurs in a yellow and an orange form (C. A. 10, 336). 4-Cyano-2-nitro-4'-methoxystilbene chloride, light yellow crystals, m. 128–30°, from C₆H₆, which become brownish red in the light. 2-Cyano-4'-methoxyphenylisatogen, small, brownish violet leaflets from C₆H₅N or PhCO₂Et, m. 257°. Conc'd. H₂SO₄ gives a deep violet color. 2-Cyano-4'-methoxyphenylindoxyl, nearly colorless, prismatic needles, darken 180°, m. 203° (decompn.). Acetyl derivative, small needles, m. 204°. o-O₂NC₆H₄C:CCO₂H is best prepd. by treating 35 g. o-O₂NC₆H₄CHBr-CHBrCO₂H with 35 g. KOH in 1100 cc. H₂O for 24 hrs. at room temp., pptg. with HCl, taking the ppt. up in 700 cc. H₂O and again treating with 35 g. KOH; yield, 14.9 g. Methyl o-nitrophenylpropiolate, prepd. by dissolving 3 g. acid in 35 cc. 3% MeOH-HCl and allowing the soln. to stand overnight, light yellow leaflets from CCl₄, m. 87–8°. Heated 3 min. with C₆H₅N at 100°, or simply by allowing the soln. to stand overnight at room temp., methyl isatogenate is formed, orange-yellow crystals, m. 201°. Oxime, light yellow needles, m. 220–1° (decompn.). Ethyl o-nitrophenylpropiolate, prepd. by dissolving 1 g. acid in 15 cc. 3% MeOH-HCl and allowing to stand 48 hrs. at room temp., light yellow leaflets, m. 62°. Ethyl isatogenate (Baeyer, Ber. 15, 780), obtained by the use of H₂SO₄ or C₆H₅N, transparent, yellow prisms, m. 111°. o,p-Dinitrocinamic acid benzene compound, (O₂N)₂C₆H₃CH:CHCO₂H.C₆H₅, long slightly yellow prismatic needles, which quickly lose C₆H₅ in the air. Methyl ester, light yellow flat needles, m. 86–8°. Methyl o,p-dinitrodichlorohydrocinammate, prepd. by passing Cl into 40 g. Me ester in 400 g. CHCl₃ in the sunlight for several days, yellow needles, m. 120°, from MeOH. Methyl o,p-dinitro-μ-chlorocinnamate, by heating 2 g. of dichloride and 10 cc. C₆H₅N 3.5 hrs. at 100°, small yellow needles, m. 125–6°. o,p-Dinitrodibromohydrocinammic acid, yellow needles, m. 212°. Methyl ester, small needles, m. 126°. o,p-Dinitrophenylpropionic acid, by the action of 135 cc. 1.1% NaOH upon 3 g. of the dibromide for 4 hrs., light yellow, flat needles, with 1 mol. C₆H₆, m. 129°. In sunlight the acid quickly becomes yellow, then orange. Methyl ester, cm.-long thin needles, m. 103.5°. Conc'd. H₂SO₄ gives a yellow color. Methyl 2-nitroisatogenate, by the action of C₆H₅N in the cold, golden yellow leaflets, m. 179–80° (decompn.). If the temp. is above 0°, the heat of the reaction decomps. the compd.

C. J. WEST.

Action of ozone upon organic compounds. IV. Additions. C. HARRIS. Univ. Kiel. Ann. 411, 158–60(1916); cf. C. A. 9, 2877.—The cyclopentylcyclopentene prepd. by H. differs from that prepd. by Wallach (C. A. 6, 2078) in optical properties, probably because different agents were used for removing H₂O. The fact that different decompn. products were obtained from the distn. of hexamethylpentamethylenediammonium hydroxide than were obtained by v. Braun (C. A. 6, 982) is probably explained by a difference in the manner of distn.

C. J. WEST.

Heptamethylenebis(α-imino acids) and stereoisomerism of their copper salts. N. A. SHLEZINGER. J. Russ. Phys. Chem. Soc. 47, 1811–9(1915).—Each of the Cu salts of the bisimino acids (C. A. 9, 2067, 3053) exists in 2 modifications, a blue and a violet, differing so radically from each other that the difference cannot be explained by "phys. variation" (cryst. form, fineness of powder, etc.). S. considers them *cis-trans* isomers, assuming the blue to have the *cis* and the violet the *trans* form:

When $x < 5$ only the *cis* compd. is stable; with increasing x the stability of the *cis* compd. gradually diminishes, while that of the *trans* compd. increases. When $x = 7$ the *cis* compd. becomes labile and the *trans* compd. stable, and they are mutually convertible into each other. The following new compds. were prepd.: *Heptamethylenebis- $[\alpha$ -iminoisobutyric nitrile]*, $(\text{CH}_3)_7[\text{NHC}(\text{CN})\text{Me}_2]_2$, very viscous, almost colorless oil. *Hydrochloride*, $\text{C}_{11}\text{H}_{22}\text{N}_4 \cdot 2\text{HCl}$, m. in sealed capillary 129° . The *acid*, $\text{C}_{11}\text{H}_{20}\text{N}_2\text{O}_4$, does not m. even above 310° . *Copper salt*, $\text{C}_{11}\text{H}_{22}\text{N}_4\text{O}_4\text{Cu} \cdot 0.5\text{H}_2\text{O}$ (by interaction of the acid with $\text{Cu}(\text{OH})_2$ in NH_4OH), red-violet crystals, sol. only in fused PhOH , giving a red soln. at low and a blue at elevated temps.; kept hot, the blue soln. slowly recovers the red color. When the red soln. is treated with much H_2O (to dissolve excess of PhOH) and the insol. part is dissolved in alc. the resulting soln. slowly turns blue, and upon addition of Et_2O deposits the blue modification which remains unchanged upon recrystn. from alc., but heating for 1 min. with H_2O reconverts it into the violet modification. *Heptamethylenebis- $[\alpha$ -iminophenylacetic nitrile]*, $(\text{CH}_3)_7[\text{NHCH}(\text{CN})\text{Ph}]_2$, thick oil. *Hydrochloride*, $\text{C}_{22}\text{H}_{22}\text{N}_4 \cdot 2\text{HCl}$, turns yellow 142° , m. 144° (decompn.), insol. in cold, decomd. by hot H_2O . The *acid*, $\text{C}_{22}\text{H}_{20}\text{N}_2\text{O}_4$, cryst., m. 231° . *Hydrochloride*, $\text{C}_{22}\text{H}_{20}\text{N}_2\text{O}_4 \cdot 2\text{HCl} \cdot \text{H}_2\text{O}$, has no definite m. p. *Copper salt*, $\text{C}_{22}\text{H}_{20}\text{N}_2\text{O}_4\text{Cu}$, blue, insol. in H_2O . *Methyl ester*, $\text{C}_{22}\text{H}_{24}\text{N}_2\text{O}_4$, very viscous oil, d_4^{20} 1.0854, n_D^{20} 1.5293. H. M. GORDIN.

Action of hydrazine on dibenzalacetone. Transformation into derivatives of cyclopropane and cyclopentane. N. KIZHNER. *J. Russ. Phys. Chem. Soc.* 47, 1819-48 (1915).—Notwithstanding their constitutional similarity, dibenzalacetone (a) reacts with N_2H_4 in a more complex manner than phorone (b) (C. A. 7, 3965). With 1 mol. of N_2H_4 (a) gives the normal compd. (I) which, however, upon warming yields (III),

and not a cyclopropane deriv. as is the case with (b). With an excess of N_2H_4 2 mols. of (I) unite with another mol. of N_2H_4 to form (II) which HCl decomp. with regeneration of (I) and N_2H_4 (both as HCl salts), but when heated (II) breaks up in 2 directions, one part again regenerating (I) which then further yields (III), while another part

gives the satd. base (IV) which under the conditions of reaction is very stable, but heating with KOH in presence of catalyzers decomp. it with formation of (V). The

pyrasoline (I), yellow needles, m. $77-8^\circ$. When larger amts. of it are heated it decomp. with formation of (III). *Hydrochloride*, $\text{C}_{17}\text{H}_{18}\text{N}_2\text{HCl}$, yellow crystals, m. $169-70^\circ$ with evolution of HCl ; its soln. has an orange color, and when the salt is heated for some time it loses all of its HCl and isomerizes to (VII). The compound (II), white

needles, m. $55-60^\circ$, stable *in vacuo*, but deliquesces in the air, cannot be recrystd. without decompn. 1,2-Diphenyl-3-cyclopentene (III), b_{747} 321.5° , d_4^{20} 1.036, n_D^{20} 1.5881, forms a *dibromide* (VIII), rhombs, m. 119° . The *pyrasoline* (IV), thick liquid, b_{10} 222° , d_4^{20} 1.0625, n_D^{20} 1.5874, forms a liquid *hydrochloride* which turns violet in the air. The *hydrocarbon* (V), odorless liquid, had slightly different properties according to the

conditions of prepn., b_{10} 204.5°, d_4^{15} 0.9995, n_D^{15} 1.5666, or b_8 176°, d_4^{15} 1.0063, n_D^{15} 1.5718, forms a *nitroso compound* (VI) (light yellow needles, m. 151°) which unites with C_6H_6 to form the compound $(C_{17}H_{15}N_2O)_2 \cdot C_6H_6$, golden yellow needles, loses all of the C_6H_6 at 100°. The *pyrasoline* (VII), crystals, m. 97.5°, b_{10} 255°, b_{748} 424°, forms a *hydrochloride*, m. 202-4°. Reduction of (III) in presence of Pt black yields (IX) pre-

viously made by K. (C. A. 6, 84). When (V) is treated with HBr and the resulting *bromide* decompd. with KOH an unsatd. *hydrocarbon* $C_{17}H_{14}$ was obtained which most probably is $(\text{PhCH}_2\text{CH}_2\text{CH})_2$, though other formulas are possible, b_{748} 328°, b_{11} 180°, b_8 172°, d_4^{20} 1.0226, n_D^{20} 1.5872, forms a *dibromide*. H. M. GORDIN.

Interaction of benzoyl chloride with *m*-xylene in presence of some of the halides of the metals of the second group. B. N. MENSHTUKIN. *J. Russ. Phys. Chem. Soc.* 47, 1853-84 (1915).—In order to see whether other salts can take the place of AlCl_3 in the prepn. of ketones from acyl chlorides and aromatic hydrocarbons, M. examd. the interaction of BzCl with *m*-xylene in presence of CaCl_2 , CaBr_2 , SrCl_2 , SrBr_2 , BaCl_2 , BaBr_2 , CdCl_2 , CdBr_2 , MgCl_2 , ZnCl_2 , ZnBr_2 , HgCl_2 or HgBr_2 . The reaction: $\text{BzCl} + \text{Me}_2\text{C}_6\text{H}_4 = \text{BzC}_6\text{H}_4\text{Me}_2 + \text{HCl}$, being dimol., the usual equation for dimol. reactions was used, detg. the reaction velocity by detg. from time to time the amt. of HCl (absorbed in KOH) produced. Briefly summarized the results were as follows: In absence of any of these salts there was no noticeable reaction. If the salts were not completely dehydrated some HCl was liberated, but this was due to the action of the remaining H_2O on BzCl , the product consisting of BzOH only. In perfectly anhydrous state the salts favorably influenced the velocity of the reaction, but with the exception of the Zn and Hg salts all the above salts had such a negligibly slight influence as to make it reasonably certain that whatever HCl was evolved was due to incomplete dehydration. The Hg and the Zn salts, particularly the latter, make the formation of ketone go readily, but requiring a temp. of 140-50° to be effective cannot replace AlCl_3 for substances boiling below this temp. With all the halides of Zn and Hg the reaction does not start until a certain amt. of a black resinous substance is produced which seems to be the active agent and which must be brought into contact with the different parts of the reaction mixt. by vigorous stirring. For this reason when the salts used are in lumps the value of the velocity const. (K) at first continually grows, becoming const. only when sufficient of the black resin has been formed, while with the salts in very fine powder, offering a larger surface for the formation of the resin K is const. from the start for the Zn salts but not for the Hg salts. This is due to the high sp. gr. of the Hg salts making thorough mixing difficult. For each of the Zn and the Hg salts the value of K irregularly varies with the concn. up to a certain limit when increasing the salt concn. has no further effect on K . Expressed in mols. of salt for 1 mol. each of BzCl and *m*-xylene the limiting values of concn. are 0.38, 0.26, 0.18 and 0.26 for ZnCl_2 , ZnBr_2 , HgCl_2 and HgBr_2 , resp. In this respect there is thus a radical difference between these salts and SbCl_5 whose value of K is proportional to the square of its concn. (Menshutkin, "Influence of Substituents on Some Reactions of Benzene and Its Substituted Derivs.," Petrograd, 1912.) SbCl_5 forms with hydrocarbons stable compds. that are not decompd. even at 150°, hence it may be used even for substances boiling below this temp., the mixt. remaining homogeneous throughout the reaction, while ZnBr_2 forming no such compds. cannot be used for liquids boiling below this temp., volatilization causing them to go up into the condenser and by dropping back into the liquid making the mixt. inhomogeneous. A great many tables accompany H. M. GORDIN.

New methods of obtaining divinyl, isoprene, piperylene and dimethylethyrene. I. OSTROMUISLENSKII. *J. Russ. Phys. Chem. Soc.* 47, 1947-78(1915).—Aldol (a) was made by digesting AcH with K_2S at 16° for 12 hrs. and after removing the K_2S electrolyzing the (a) in presence of dil. H_2SO_4 . The (a) changes to butylene glycol which upon dehydration gave erythrene (b). A detailed table is given for concn., current strength, yield of glycol, etc. A general method for making (b) is based upon O.'s rule that open chain hydrocarbons with 1 double union and satd. cyclic hydrocarbons usually decomp. when heated to a high temp. in such a manner that all but 4 C atoms are eliminated as satd. hydrocarbons, the result being (b). Thus $Me_3CHCH:CH_2$ and $Me_3C:CHMe$ give $CH_4 + (b)$, and $MeEtCHCH:CH_2$ gives $Me_2 + (b)$. In the same way methylcyclohexane gives $Me_2 + C_2H_4 + (b)$. $Me_2CHCH_2CH_2OH$ gives at $500-600^\circ$ $H_2O + CH_4 + (b)$, while Me_2CClEt and $Me_2CHCH_2CH_2Cl$ give $HCl + CH_4 + (b)$. The pyrogenetic depolymerization of polymers gives monomers, so that dibutene gives (b), dipentene isoprene (c), and dihexene β,γ -dimethylethyrene (d). When pure limonene (e) is boiled for a long time part of it polymerizes to higher polyterpenes, while another part depolymerizes to (c). Na accelerates, while C_6H_6 prevents the reaction. When, however, a mixt. of the vapors of (e) and C_6H_6 , PhMe or petr. ether is heated to $500-600^\circ$ (c) is produced in large amts. That this is due to a lowering of the b. p. of (e) and not to mere diln. was shown by the low yield of (c) when the diluent had a high b. p., e. g., $C_{11}H_{22}$. Instead of (e) French or Russian oil of turpentine may be used. Myrcene and natural caoutchouc also give (c) under these conditions. This leads O. to setting up another rule that, unlike compds. with 1 double union, the polymers of diolefins, both cyclic and non-cyclic, give upon pyrogenetic depolymerization the corresponding diolefin monomers instead of (b). This shows that at least in reactions of depolymerizations the double union is more stable than the single union. In further search of methods for making (c) the action of several substances on $Me_2CClCH_2CH_2Cl$ (f) was tried. Fused KOH, Zn, CaO, BaO and numerous other reagents were found to be ineffective, while for amines the following rule was established: Amines of strong basicity react with (f) in no regular manner, but when their basicity is reduced to a certain degree they eliminate 2 HCl from it, changing it to (c). Thus $MeC_6H_4NH_2$ reacts with it with almost explosive violence, removing only 1 HCl and changing it to $Me_2C:CHCH_2Cl$ (g) which condenses with the amine to $MeC_6H_4NHCH_2CH:CM_2$ with elimination of another mol. of HCl. On the other hand, quinoline (h) readily converts (f) into (c). Even strong bases become suitable for the purpose when their basicity is reduced by the introduction of certain radicals. Thus $p\text{-}ClC_6H_4NH_2$ (i) and $p\text{-}BrC_6H_4NH_2$ (k), anisidine and tetramethyldiaminobenzophenone (l) give with (f) a good yield of (c). In the interaction of (f) with (h), (i), (k) or (l) the (c) is accompanied by basic dyes having the character of indicators, being colored red or violet by acids, but upon neutralization the color disappears with the pptn. of a gray amorphous substance. NO_2 groups lower the basicity of amines to such an extent that they do not react with (f). Both $CH_2:CM_2CH_2CH_2Cl$ (m) and (g) are changed by (h) to (c), the (g) evidently changing first to $Me_2C:C:CH_2$ (n) which then isomerizes to (c). Na stearate (p) also changes (m) to (c), but (g) it changes to (n) only, so that this reaction may serve to distinguish between (m) and (g). With (f), (p) hardly reacts at all. In presence of Al_2O_3 at $380-450^\circ$ iso-AmOAc gives (c) + AcOH. Dehydrated with Al_2O_3 at $400-50^\circ$ or with HPO_3 at 300° $Me_2C(OH)CH_2CH_2OH$ gives about 10% of (c). The conversion of piperylene into (c) was given in a former article (not yet abstrd.). A good method for obtaining (d) is by the dehydration of pinacol (q) by means of sulfanilic acid, HPO_3 or the acid salts of the latter. In general it was found that when an acid is capable of changing (q) to pinacolin (u) its acid salts

will dehydrate (*g*) to (*d*), and that NH_3 acids act like such salts. The acids reacting in this manner were found to be readily esterifiable, so that any agent facilitating esterification promotes the formation of (*d*) and (*u*). Thus a mixt. of (*f*) with phthalic anhydride and glacial H_2SO_4 or salts of the latter gave 13% of (*d*) and 74% of (*u*). The yield of (*d*) is improved when in Couturier's method (*Ann. chim. phys.* [6] 26, 433) the H_2SO_4 is dild. not with H_2O but with some org. solvent, *e. g.*, $\text{Me}_2\text{CHCO}_2\text{H}$, the latter partly reducing the H_2SO_4 to SO_2 which unites with the (*d*) to form $m(\text{SO}_2) \cdot n(\text{C}_6\text{H}_5)_2$. KHSO_3 gives with (*g*) 35%, acid toluidine sulfate about 30%, and neutral toluidine sulfate about 20% of (*d*), but in the latter case additional amts. of (*d*) may be obtained by repeated distn. of the residue. With both toluidine salts the reaction goes at a comparatively low temp., but there is so much resinification that the toluidine cannot be recovered from the residue without considerable loss. Many of the pyrogenetic reactions in this work were carried out in a special lamp of the parts of which cuts are given.

H. M. GORDIN.

Transformation of cyclobutane derivatives (monobromocyclobutane and cyclobutanol) into erythrene. Mechanism of removal of radicals in the positions 1 and 4. I. OSTROMUISLENSKII. *J. Russ. Phys. Chem. Soc.* 47, 1978-82 (1915).—Since $\text{CH}_2(\text{CH}_2\text{Br})_2$ reacts with Zn to form $\text{CH}_2\text{CH}_2\text{CH}_2$, and since the latter readily isom-

erizes to $\text{MeCH}:\text{CH}_2$, we are justified in assuming that the conversion of $\text{CH}_2\text{BrCH}:\text{CHCH}_2\text{Br}$ into $\text{CH}_2:\text{CHCH}:\text{CH}_2$ (*a*) by the action of Zn passes through $\text{CH}_2\text{CH}:\text{CH}:\text{CH}_2$ (*b*). If this view be correct Thiele's assumption that this change

is due to partial valences is superfluous, and any reaction in which (*b*) ought to be produced ought finally to give (*a*). This is corroborated by the formation of (*a*) by the elimination of HBr from monobromocyclobutane by means of quinoline, KOH in alc. or BaCl_2 , and of H_2O from cyclobutanol by means of Al_2O_3 . It may be expected that homologs of cyclobutane or cyclobutanol will give when heated or under the influence of catalyzers homologs of (*a*).

H. M. GORDIN.

Analysis, purification and qualitative reaction of isoprene. II. Structure of the benzene nucleus. I. OSTROMUISLENSKII. *J. Russ. Phys. Chem. Soc.* 47, 1983-8 (1915).—Isoprene (*a*) may be detected by adding 5-10 drops of it to 50 cc. of concd. aq. SO_2 and letting the mixt. stand for 2-30 hrs. in a tightly stoppered vessel. In presence of (*a*) a colorless, amorphous ppt. appears. The reaction is general for compds. with conjugated double unions, and the ppt. is a combination of diolefin and SO_2 . The ppt. is sol. in aromatic amines only, and when reprecipitated from such soln. by alc. is a snow-white colloid resembling caoutchouc. On prolonged standing in the air it gradually loses its elasticity and plasticity, becomes sticky, and finally falls to fine powder. Quantitatively (*a*) may be detd. by converting it into $\text{Me}_2\text{CClCH}_2\text{CH}_2\text{Cl}$ (*b*). For this purpose 200 g. of the crude (*a*) is mixed with 1.5 l. of 30% HCl and the mixt. shaken for 6 hrs. The black upper layer consisting of a mixt. of (*b*) with other chlorides is sepd., washed with a satd. soln. of NaCl , digested for 10-6 hrs. with CaCl_2 and fractionally distd. The fraction *b*. 142-3°, consisting of (*b*), is weighed and from its amt. the amt. of (*a*) is calcd. To purify (*a*) when mixed with amylene, etc., which interfere in its polymerization to caoutchouc the crude product is twice subjected to fractional distn., using a dephlegmator filled with Al shavings and collecting the fraction *b*. 42°. Further fractionation is useless, the (*a*) volatilizing with the amylenes. The product (3 kg.) is digested for 10-24 hrs. with Na wire (8-10 g.), then mixed with BaO_2 (100 g.), the mixt. boiled under reversed condenser for 1 hr. and distd. The product contains 90-100% of (*a*) and is free from amylenes, but may contain satd. hydrocarbons. Chem. pure (*a*) is obtained by the interaction of $\text{CH}_2\text{BrCHBrCMe}:$

BrCH_2Br in alc. with Zn dust. The bromide is made by acting with Br in CHCl_3 on (a) purified as above, and the Zn is taken in double the required amt. Pure (a) b. $33.2-3.8^\circ$. When warmed with Na it gives a peculiar (abnormal) caoutchouc different from the "Na isoprene caoutchouc" described by Matthewson and later by Harries. The lack of reactivity of halogen directly linked to the C_6H_5 ring O. explains by the observation that in general halogen situated at a double union is comparatively immobile even in the aliphatic series (O., "Theory of the C_6H_5 Nucleus and Ethylene Unions," Moscow, 1909). The analogy is supported by the fact that $\text{CH}_2\text{:CHBr}$ and MeCH:CHBr just as readily react with Na or Mg as aromatic halides (Austerweil, Ger. pat. 245,180, C. A. 6, 2334). Hence Armstrong-Baeyer's central formula for CH_2 devised for the sole purpose of accounting for the stability of the C_6H_5 ring in oxidation reactions must be rejected in favor of Kekulé's formula which makes C_6H_5 with its conjugated unions a complete analog of erythrene. H. M. GORDIN.

Transport of the elements of halogen acid from one organic radical to another. Mechanism of the action of chlorine on β -isoamylene. I. OSTROMUISLENSKII. *J. Russ. Phys. Chem. Soc.* 47, 1988-91(1915).—The chlorination of $\text{Me}_3\text{C:CHMe}$ (a) gives, among other things, $\text{C}_6\text{H}_{11}\text{Cl}$ (b). It is generally assumed that (b) results from the intermediate formation of trichloroisopentane (c) which gives off 1 mol. of HCl to unchanged (a), converting the latter into (b). A quant. examn. of the product obtained by chlorinating 100 g. of (a) showed the production of 50 g. of (b) but only 8 g. of (c). If the above view were correct 85 g. of (c) ought to have been produced. Hence O. explains the formation of (b) by assuming the intermediate formation of $\text{Me}_3\text{CClCHClMe}$ which transfers 1 mol. of HCl to 1 mol. of (a), converting the latter into (b) and itself changing to $\text{C}_6\text{H}_5\text{Cl}$. H. M. GORDIN.

New method of making esters of unsaturated alcohols from aldols. I. Crotonyl acetate. I. OSTROMUISLENSKII. *J. Russ. Phys. Chem. Soc.* 47, 1991-3(1915).—The interaction of aldol (50 g.) with Mg-Hg (12 g. Mg in excess of Hg) gave crotonyl acetate (a) (Charon, *Ann. chim. phys.* [7] 17, 249). In a short time the mixt., placed in a flask with a reflux condenser, becomes hot. To it C_6H_6 (100 g.) is added slowly, and when the spontaneous boiling ceases the mixt. is heated to about 100° for 4 hrs. The C_6H_6 soln. is filtered off through glass wool, the black residue decompd. with H_2O , and after warming on the H_2O bath for 2-3 hrs., extd. successively with aq. acetone, Et_2O and C_6H_6 . The last C_6H_6 ext. is united with the 1st C_6H_6 soln. and after washing with H_2O and drying with Na_2SO_4 , the C_6H_6 is distd. off. The residue consists of aldehyde resin (16 g.) and crude (a) (19 g.). The latter is purified by fractional distn. under 25 mm. It is supposed that part of the aldol decompd. into AcH which condenses with another part to form the monacetin of 1,3-butyleneglycol. The latter then loses H_2O , changing to (a): $\text{MeCH(OH)CH}_2\text{CHO} = 2\text{AcH}$; $\text{AcH} + \text{MeCH(OH)CH}_2\text{CHO} = \text{MeCH(OH)-CH}_2\text{CH}_2\text{OAc}$; $\text{MeCH(OH)CH}_2\text{CH}_2\text{OAc} = \text{H}_2\text{O} + \text{MeCH:CHCH}_2\text{OAc}$. Al_2O_3 changes (a) smoothly to erythrene (60-70%) and AcOH. Should the analogs and homologs of aldol behave in a similar manner the reaction would be available for making esters of unsatd. alcs. H. M. GORDIN.

Atomic refraction of phosphorus in some of its organic compounds. A. E. ARBUZOV AND A. A. IVANOV. *J. Russ. Phys. Chem. Soc.* 47, 2015-27(1915).—With a view to finding whether the n of P is the same in different homologous series and for its different valences, the n of P(OEt)_3 , EtPO(OEt)_2 , $\text{P(OEt)}_2\text{OH}$ and PO(OEt)_3 was detd. for different lines of the spectrum. It was found that for compds. with 3-valent P n is greater than for those with 5-valent P. The difference is 3 units if in the calcns. one O in the 5-valent P compds. is taken with a double union to P, and 2 units if all the O in these compds. are taken with single unions to P. Hence the formulas with one O doubly linked to P are to be preferred. The value of n for the compds. with 5-

valent P was not const. This is ascribed to differences in constitution, in the 2nd of the above compds. the P being linked to O and C, in the 3rd (written as $\text{PO}(\text{OEt})_2\text{H}$) to O and H, and in the 4th to O alone. While in simple compds. like hydrocarbons with only 2 different elements constitution has little influence, in compds. like the above with 4 different elements the influence of constitution is very pronounced. Owing to Zecchini's (*Z. physik. Chem.* 12, 504) having worked with an entirely different substance or possibly a mixt. of substances which he took for $\text{P}(\text{OEt})_3$, his results for the n of this compd. differ from those obtained by the authors. As was shown by A. the substance designated in Z.'s time Et phosphite was a complex of several esters (*J. Russ. Phys. Chem. Soc.* 38, 203). Detns. of the at. vol. of P gave no const. results for compds. with 5-valent P, but the ratio at. vol. : n was quite const. when the authors' values for both detns. were used.

H. M. GORDIN.

The scission of some nitrogen compounds. A. ANGELI. Florence. *Atti accad. Lincei* 24, I, 1093-8(1915).—Some years ago A. (*Mem. accad. Lincei* 1905, 83) showed that the Na salt of nitrohydroxylamine, $\text{HON}:\text{NO}_2\text{Na}$, decomps. easily to give $\text{HNO} + \text{HNO}_2$ and that hydroxylaminesulfonic acid, $\text{HON}:\text{SO}_3(\text{OH})\text{H} \rightarrow \text{HNO} + \text{H}_2\text{SO}_4$ and $\text{HON}:(\text{Ph})\text{SO}_2\text{H} \rightarrow \text{HNO} + \text{PhSO}_2\text{H}$. These acids are derivs. of NH_2OH with HNO_2 , H_2SO_4 and PhHSO_3 which on breaking up give HNO_2 , H_2SO_4 and PhHSO_3 instead. Similar scissions will be expected from other elements that form acids in 2 stages of oxidation. These reactions are probably really hydrolytic processes, thus: $\text{PhSO}_2\text{NHOH} + \text{H}_2\text{O} \rightarrow \text{PhSO}_2\text{H} + \text{NH}(\text{OH})_2$, since the disubstituted derivs. undergo a similar decompn. that can only be represented thus: $(\text{PhSO}_2)_2\text{N}(\text{OH}) + \text{H}_2\text{O} \rightarrow \text{HNO}_2 + 2\text{PhSO}_2\text{H}$. Given the analogy in behavior of derivs. of NH_2OH , N_2H_4 (and H_2O_2) (cf. C. A. 5, 94) it appears that similar scissions may be foreseen in the derivs. of N_2H_4 and A. has studied the action of alkalis on $\text{PhSO}_2\text{NHNH}_2$. Raschig (C. A. 5, 3020) found the reaction complete at high temps. with the evolution of $\text{N}_2 + \text{H}_2$ and formulated it thus: $\text{PhSO}_2\text{NHNH}_2 + \text{H}_2\text{O} \rightarrow \text{PhSO}_2\text{H} + \text{NH}_2\text{NH}(\text{OH})$. The latter by loss of H_2O gives $\text{HN}:\text{NH}$ and this decomps., giving $\text{H}_2 + \text{N}_2$. Thiele (*Ann.* 271, 130) says that $\text{HN}:\text{NH}$ decomps. thus: $2\text{N}_2\text{H}_2 \rightarrow \text{N}_2 + \text{N}_2\text{H}_4$. But A. observed (C. A. 5, 94) that in the presence of dil. mineral acids $2\text{N}_2\text{H}_2 \rightarrow \text{HN}_2 + \text{NH}_3$ (analogous to $2\text{HNO} \rightarrow \text{N}_2\text{O} + \text{H}_2\text{O}$). The latter interpretation is accepted by Diels (C. A. 7, 2948). A. has shown (C. A. 4, 1620) that $\text{PhSO}_2\text{NHNHPh}$ loses PhSO_2H by the action of alkali and the $\text{PhN}:\text{NH}$ formed reacts immediately with BzH for example. If in the absence of BzH the alk. liquid is agitated with Et_2O the $\text{PhN}:\text{NH}$ reacts with the unchanged $\text{PhSO}_2\text{NHNHPh}$ to give $\text{PhN}:\text{NSO}_2\text{Ph} + \text{PhNHNH}_2$. On the basis of this it was expected that N_2H_4 derivs. containing 2 sulfonyl groups united 1 each to the 2 N atoms would undergo a similar reaction. Hinsberg (*Ber.* 27, 601(1894)) prepd. $(\text{NHSO}_2\text{Ph})_2$, which gave a K salt which by heating decomps., giving PhSO_2H and N_2 . It seems that $(\text{NHOH})_2$ may be intermediate here and decomps. to give $\text{N}_2 + 2\text{H}_2\text{O}$. The reaction may be $(\text{NHSO}_2\text{Ph})_2 \rightarrow \text{N}_2 + 2\text{PhSO}_2\text{H}$ in which $\text{HONHNHSO}_2\text{Ph}$ is an intermediate. In the study of this reaction the same method was used as in the study of the decompn. of benzenesulfohydroxamic acid in which the $\text{NH}(\text{OH})_2$ was fixed with aldehydes or PhNO ; with the latter $\text{PhN}(:\text{O}):\text{NOH}$ was formed. PhNO reacting with $(\text{NHSO}_2\text{Ph})_2$ in alk. soln. gives $\text{PhSO}_2\text{NHN}:\text{N}(:\text{O})\text{Ph}$ as colorless crystals, exploding at 102° as well as by percussion. Since it is acid the salts are probably derived from the tautomer $\text{PhSO}(\text{OH}):\text{NN}:\text{N}(:\text{O})\text{Ph}$. With Fe^{III} and Cu it gives complexes similar to those of "cupferon." By the action of alk. it loses another mol. of PhSO_2H and gives a product, probably $\text{PhN}(:\text{O}):\text{N}:\text{N}$, that decomps. into $\text{PhNO} + \text{N}_2$. The reactions are being studied further.

E. J. WITZERMANN.

The stereoisomeric oxime of β -naphthyl phenyl ketone. PASQUALE POCCIANI. Florence. *Atti accad. Lincei* 24, I, 1135-7(1915); complete in *Gazz. chim. ital.* 45

II, 111-20(1915).—In a preceding paper Betti and P. (*C. A.* 9, 3021) showed the existence of 2 stereoisomers of α - $C_{10}H_7CPh:NOH$, one of which m. 127° , the other 161° , of which the 1st may be transformed into the 2nd. Kegel (*Ann.* 247, 181(1888)) described a β - $C_{10}H_7CPh:NOH$, m. $174-6^\circ$. Perrier and Caille (*C. A.* 2, 2693) cite the expts. of Rousset (*Thèse Lyon*, 1896) who obtained an oxime, m. 133° . P. has found that β - $C_{10}H_7Bz$ (α) forms 2 oximes of which one crysts. from EtOH in small regular rhombohedra, m. 157° , the other crysts. in long, silky needles, m. 174° . The latter corresponds to that obtained by K. although P. could not obtain solely this form under the conditions described by him: there was always some of the other formed. The oxime, m. 133° , could not be obtained under the conditions described by P. and C. even when modified: a mixt. of the 2 forms, m. $140-5^\circ$, was always obtained. It was found, as was expected, that NH_2OH acts on the β - more easily than on the α -ketone since the CO group is in the α -position. Besides in the case of the β -oxime the transformation of 1 into the other isomer is more difficult; in fact it could not be done. This is shown by the fact that 2 Bz derivs. were obtained, while with the α -deriv. only one could be obtained: the *benzoyl derivative* of the oxime (m. 174°), m. 168° , that of the oxime (m. 157°) m. 172° . Also with $PhNCO$ 2 different addition products were obtained. In alkalis about an equal amt. of both isomers is formed. The configuration of the 2 oximes was detd. by Beckmann rearrangements with PCl_5 : the oxime, m. 174° , in this way gave β - $C_{10}H_7CONHPh$; the oxime, m. 157° , gave β - $C_{10}H_7NHBz$, thus showing that the 1st is (I) and the 2nd (II). The reduction of these 2 oximes takes place

with difficulty not found with the α -derivs. and gives an oily base that easily combines with CO_2 from the air, and of which the following compds. have been obtained: *hydrochloride*, white rosetts, m. $265-70^\circ$ (decompn.); the *acetate*, white silky needles, m. 127° ; *benzoyl deriv.*, small needles, m. 182° . This base is β -naphthylphenylaminomethane, $PHCH(NH_2)C_{10}H_7$, analogous to the amine obtained from the α -derivs. This work clears up the isomeric oximes of the naphthyl phenyl ketones about which the literature has been uncertain and contradictory. The (α) used was obtained from the mother liquors in the prepn. of α - $C_{10}H_7Bz$. The 1st sepn. of the α - and β -derivs. was done mechanically by decanting the needles of β -crystals from the heavy prisms of the α -crystals. The sepn. was completed by forming the picrate (Rousset, *Bull. soc. chim.* [3] 15, 71). 3 g. (α) in 25 cc. EtOH treated with 1.5 g. $NH_2OH.HCl$ + 1.7 g. $NaOAc$ in 5 cc. H_2O and heated 45 min. on the H_2O bath, cooled, filtered, the ppt. washed to remove $NaCl$ and crystd. from EtOH gave a mixt. of the 2 oximes m. 140° : one as white silky rosetts, m. 174° ; the other as tufts of long needles, m. 157° . Sepd. mechanically and recrystd. it gave the pure oxime. A mixt. of the pure oximes, m. 140° . 3 g. (α) in 15 cc. EtOH + 1.2 g. $NH_2OH.HCl$ in the sealed tube at $100-10^\circ$ for 5-6 hrs. gives most of the isomer that m. 174° . The same repeated with 8 cc. of 20% $NaOH$ gives nearly equal amts. of the 2 isomers. Heating the isomer that m. 157° (presumably the more unstable) in EtOH containing HCl gave no transformation into the other isomer. The Bz deriv. of the oxime m. 174° was obtained as small shining prisms from EtOH, m. 168° ; the other as small, shining needles, m. 172° ; on sapon. both gave the original oximes, resp. 0.5 g. of oxime, m. 174° , treated with 1.5 cc. $PhNCO$ in a sealed tube gave at $70-80^\circ$ for some hrs. a ppt. of the *carbanilide derivative*, cryst. powder, m. 192° . The oxime, m. 157° , similarly treated gave a *carbanilide derivative*, tufts of colorless crystals, m. 160° . Angeli and Alessandri (*Atti accad. Lincei* 22, I, 735(1913)) noted that certain oximes decomp. on heating to give N_2 and NH_3 . These oximes decomp. at the m. p.

but give no gas. They decomp. spontaneously in sealed tubes, giving nitrous fumes and a yellow-red semi-oily substance.

E. J. WITZEMANN.

The oxidation of azoketones and azonitriles. A. ANGELI. Florence. *Atti accad. Lincei* 24, I, 1185-90(1915).—In order to extend his expts. on the action of peracetic acid on the azo derivs. A. has studied its action on $\text{RN}:\text{NC}_6\text{H}_4\text{Ac}$, $\text{RN}:\text{NC}_6\text{H}_4\text{CN}$, $\text{RN}:\text{NC}_6\text{H}_4\text{CH}_2\text{CN}$, $\text{RN}:\text{NC}_6\text{H}_4\text{NMe}_2$, $\text{RN}:\text{NCN}$, and $\text{RN}:\text{N}:\text{N}$ in which R for the present is an aromatic residue. The results with the ketones and nitriles are reported here. It was found that in order to limit the oxidation to the azo group it was necessary to work in dil. AcOH at not high temps. In this way $\text{PhN}:\text{NC}_6\text{H}_4\text{Ac}$ gives $\text{PhN}(\text{:O}):\text{NC}_6\text{H}_4\text{Ac}$ (a), m. 92° , and $\text{PhN}:\text{N}(\text{:O})\text{C}_6\text{H}_4\text{Ac}$ (b), m. 132° , and $\text{PhN}:\text{NC}_6\text{H}_4\text{CH}_2\text{CN}$ gives $\text{PhN}(\text{:O})\text{NC}_6\text{H}_4\text{CH}_2\text{CN}$ (c), m. 94° , and $\text{PhN}:\text{N}(\text{:O})\text{C}_6\text{H}_4\text{CH}_2\text{CN}$ (d), m. 132° . Their structure was easily detd. by oxidizing with KMnO_4 in alk. soln. by which the side chains were transformed into CO_2H and the acids $\text{PhN}(\text{:O})\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ and $\text{PhN}:\text{N}(\text{:O})\text{C}_6\text{H}_4\text{CO}_2\text{H}$ were obtained which were identical with those previously obtained by the oxidation of the azo acid (A. and Valori, C. A. 7, 2223). The azoketone, $\text{PhN}:\text{NC}_6\text{H}_4\text{Ac}$, prepd. by condensing equimol. amts. of PhNO and $p\text{-NH}_2\text{C}_6\text{H}_4\text{Ac}$ in AcOH, rose laminas from EtOH, m. 115° ; with NH_2OH it gives an oxime, $\text{PhN}_2\text{C}_6\text{H}_4\text{C}(\text{:NOH})\text{Me}$, m. 169° . The azoketone oxidized in AcOH with perhydrol gave 2 isomeric azoxy compounds that were sepd. by their different soly. in EtOH; the less sol. (b) recrystd. from C_6H_6 , m. 132° ; the other (a) purified from ligroin, m. 92° . (b) gave an oxime, m. 181° . (b) oxidized with KMnO_4 in the presence of a little KOH gave a yellow liquid which on treatment with dil. H_2SO_4 sepd. $\text{PhN}:\text{N}(\text{:O})\text{C}_6\text{H}_4\text{CO}_2\text{H}$, which for better identification was converted with Br into $p\text{-BrC}_6\text{H}_4\text{N}:\text{N}(\text{:O})\text{C}_6\text{H}_4\text{CO}_2\text{H}$. Both (a) and (b) give on treatment with H_2SO_4 $p\text{-HOC}_6\text{H}_4\text{N}_2\text{C}_6\text{H}_4\text{Ac}$; red, sol. in alkalis, m. 134° . Similarly condensation of PhNO with $p\text{-H}_2\text{NC}_6\text{H}_4\text{Bz}$ gives the azoketone $\text{PhN}:\text{NC}_6\text{H}_4\text{Bz}$, m. 106° , which with H_2O_2 gives an azoxy compd., m. 72° . Lack of material prevented a further study. The azonitrile, $\text{PhN}:\text{NC}_6\text{H}_4\text{CH}_2\text{CN}$, was obtained by condensing PhNO with $p\text{-H}_2\text{NC}_6\text{H}_4\text{CH}_2\text{CN}$, as orange-red laminas, m. 127° . Oxidized with H_2O_2 it gave 2 isomeric azoxy compounds, (c) and (d), that were purified by recrystn. from C_6H_6 . The more sol. one (c) m. 94° and the less sol. one (d) m. 132° . (d) oxidized with KMnO_4 gives $\text{PhN}:\text{N}(\text{:O})\text{C}_6\text{H}_4\text{CO}_2\text{H}$ which thus detcs. the structure of these isomers.

E. J. WITZEMANN.

The oxidation of dimethylaminoazobenzene. A. ANGELI. Florence. *Atti accad. Lincei* 24, I, 1190-2(1915).—Numerous expts. have shown that compds. containing $\text{RN}:\text{NR}$ are transformed by the action of peracetic acid into $\text{RN}(\text{:O}):\text{NR}$ and take up only 1 atom of O. Working under more energetic conditions it would be possible to obtain products of more profound oxidation but certainly not $\text{RN}(\text{:O}):\text{N}(\text{:O})\text{R}$ since this is the dimol. form of RNO which is easily oxidized to RNO_2 . If the azo compd. contains a 3rd atom of trivalent N the reaction is quite different. If the 3rd N is an NH_2 it undergoes oxidation probably through the NHOH deriv. to the NO_2 deriv. and is in part transformed into compds. containing new azo and azoxy groups. With a disubstituted amine the case is simpler. A. used $p\text{-Me}_2\text{NC}_6\text{H}_4\text{N}:\text{NPh}$, (a), which suspended in glacial AcOH gave a rose-colored liquid to which perhydrol was added in excess and allowed to stand several days at room temp., after which the liquid became yellow-brown. Dilg. with H_2O and treating with dil. H_2SO_4 sepd. a ppt. of the sulfate, $(\text{C}_{14}\text{H}_{15}\text{N}_3\text{O}_2)_2\cdot\text{H}_2\text{SO}_4$, of the new base in orange-yellow laminas, m. 156° (decompn.). Dissolved in H_2O and treated with Na_2CO_3 it seps. bright golden laminas of the compd. (b), $\text{C}_{14}\text{H}_{15}\text{N}_3\text{O}_2$, m. 127° (decompn.), sol. in most solvents. (b) treated with H_2S gives (a); the same result is obtained with $\text{NH}_2\text{OH}\cdot\text{HCl}$ or $\text{N}_2\text{H}_4\cdot\text{H}_2\text{SO}_4$. There are 2 possible formulas for (b): (1) $\text{PhN}:\text{N}(\text{:O})\text{C}_6\text{H}_4\text{N}(\text{:O})\text{Me}_2$ and (2) $\text{PhN}(\text{:O})\text{NC}_6\text{H}_4\text{N}(\text{:O})\text{Me}_2$. (b) treated with Br and then reduced with $\text{Sn} + \text{HCl}$ gave a base which

with BzCl gave $p\text{-BzNHC}_6\text{H}_4\text{Br}$, thus proving that (b) is (1). A. considers the sulfate as probably an oxonium salt of the $\text{-N}(\text{:O})\text{Me}_2$ group. Since (a) is yellow and its salts red, Hantzsch (*Ber.* 46, 1149(1913)) considers the free form RN:Ar:N.NPh.R

and the salts as derivs. of $\text{PhNH.N:ArX} \rightleftharpoons \text{NR}_2$. Both the free form and salts of (b) have the same color which may be explained if the dimethylated N atom is pentavalent. Such forms as those of H. would then not be possible. The Na salt of helianthine (Me orange) similarly treated in AcOH with H_2O_2 gives yellow crystals, m. 233° (decompn.), which are to be studied further. E. J. WITZEMANN.

The preparation and decomposition of phenylnitroformaldehyde phenylhydrazone. R. CIUSA AND G. BENELLI. Univ. Bologna. *Atti accad. Lincei* 24, II, 20-5(1915).—In a preceding paper (*C. A.* 8, 489) the fact was brought out that $\text{O}_2\text{NCPh:NNHPh}$ (a) is decompd. by heat thus: (a) $\rightarrow (\text{PhC:NNHPh})' + \text{NO}_2$, which is similar to the decompn. of ONCPh:NHNPh into $(\text{CPh:NNHPh})_2 + 2\text{NO}$ (Bamberger, Pemsel, *Ber.* 36, 161, 347). These decompns. resemble the following: $\text{CPh}_2\text{NO}_2 \rightleftharpoons \text{Ph}_2\text{C} + \text{NO}_2$; $\text{CPh}_2\text{NO} \rightleftharpoons \text{CPh}_2 + \text{NO}$ and $\text{NPh}_2\text{NO} \rightleftharpoons \text{NPh}_2 + \text{NO}$. The present paper is a report on the secondary products of the reaction. The best way of studying the decompn. of nitrohydrazones consists in heating with a reflux condenser a soln. of dry nitrohydrazone in xylene (dried over Na) and facilitating the loss of NO_2 by passing a stream of dry N_2 . In this way NO_2 was evolved in proportions varying with the rapidity of heating and the current of N_2 and the amt. of moisture present. On cooling the compd. $\text{CHPh:NNPhC}_6\text{H}_4\text{Me}_2\text{NO}_2$ seps. as white needles, m. 170° , gives PhNHNH_2 on hydrolysis with H_2SO_4 , and arises from the following reactions: (1) $\text{O}_2\text{NCPh:NNHPh} \rightarrow \text{NO}_2 + (\text{PhC:NNHPh})$; (2) $2(\text{PhC:NNHPh}) + \text{C}_6\text{H}_4\text{Me}_2 \rightarrow \text{Me}_2\text{C}_6\text{H}_4\text{CPh:NNHPh} + \text{PhCH:NNHPh}$; (3) $\text{Me}_2\text{C}_6\text{H}_4\text{CPh:NNHPh} + \text{NO}_2 \rightarrow \text{O}_2\text{NC}_6\text{H}_4\text{Me}_2\text{CPh:NNHPh}$. On cong. the mother liquor a small amt. of a red liquid, m. 195° , seps., which may be the product of the action of NO_2 on PhCH:NNHPh in reaction (2). The action of NO_2 on PhCH:NNHPh in Et_2O (Ciusa, Pestalozza, *idem* 17, 844) gives (1) PhN_2NO_2 and (2) dibenzaldiphenylhydrotetrazone, which are easily sepd. from the reaction mixt. by filtration. The hydrotetrazone is freed from the other by washing with H_2O and crystg. from C_6H_6 and EtOH . On evapg. the Et_2O a red substance was obtained which on crystg. from $\text{C}_6\text{H}_6 + \text{EtOH}$ gives (a), the main product of the reaction. In order to sep. the secondary products the whole was digested with 10% KOH in which a red compound, $\text{C}_{22}\text{H}_{20}\text{O}_2\text{N}_4$, dark red needles, m. 183° , remains undissolved. This compd. was obtained by Bamberger and Pemsel (*Ber.* 36, 84(1903)) as a secondary product in the oxidation of PhCH:NNHPh with AmNO_2 . The alk. soln. on adding acid or better CO_2 ppts. a brick-red compd., $\text{C}_{12}\text{H}_{11}\text{O}_2\text{N}_4$, m. $102-3^\circ$. Digesting with MeOH exts. a compd. of the same compn., m. 135° , while $\text{O}_2\text{NCPh:NNHPh}$ remains undissolved. Since $o\text{-O}_2\text{NC}_6\text{H}_4\text{NHN:CHPh}$ occurs in 2 forms and the p -deriv. in 3, none of which is identical with the above, C. and B. propose the formula PhCNO_2 for the one

m. 102° and PhCNO_2 for that which m. 135° . From the alc. in which the reaction

mass was dissolved a small amt. of a compd., yellowish needles, m. $202-4^\circ$, was sepd. which is possibly tetraphenyltetrazoline (cf. B. and P., *l. c.*). Thus 6 different products were isolated from this mixt. E. J. WITZEMANN.

Aromatic substance containing multivalent iodine. X. Peculiar compounds obtained in Sandmeyer's reaction applied to naphthalene derivatives. L. MASCARELLI AND G. MARTINELLI. Univ. Cagliari. *Atti accad. Lincei* 24, II, 25-30(1915).—During expts. on the tendency of dinaphthyl deriva. to form pentaatomic nuclei containing

plurivalent I (C. A. 8, 1760) it was necessary to prep. much of $\beta, \alpha\text{-C}_{10}\text{H}_7\text{NO}_2$ (a), from $\text{C}_{10}\text{H}_7(\text{NH}_2)\text{NO}_2$. Diazotizing the latter in HCl in the presence of H_2SO_4 (Meldola, *J. Chem. Soc.* 47, 520(1885)) in order to obtain the corresponding insol. sulfate gave in the final product after treatment with KI no (a) but 2 other compds.: (1) 1-chloro-2-iodonaphthalene (?) (b), $\text{C}_{10}\text{H}_7\text{ClI}$, white prisms, m. $83\text{--}4^\circ$, sol. in org. solvents; (2) 1-chloronaphthalene-2-diazonium chloride iodochloride (c), $\text{C}_{10}\text{H}_7\text{ClN}:\text{NCl}:\text{ICl}$, shining, golden scales, m. $146\text{--}8^\circ$, decomp. easily with H_2O with the evolution of gas, sol. in hot aq. solns. of $\text{NaCl} + \text{HCl}$ without decompn. The formation of such a diazonium iodochloride from the corresponding diazonium chloride takes place by the action of the I liberated on adding KI, thus: $\text{RN}_2\text{Cl} + \text{I}_2 \longrightarrow \text{RN}_2\text{ClI}_2 \longrightarrow \text{RI} + \text{N}_2 + \text{ICl}$ and the ICl reacts thus: $\text{RN}:\text{NCl} + \text{ICl} \longrightarrow \text{RN}:\text{NCl}:\text{ICl}$. In the above case, however, the NO_2 group is also substituted by Cl. In the C_{10}H_7 series the substituents have a certain mobility with respect to that of the C_6H_5 series and nascent Cl (from the decompn. of ICl) may attack the NO_2 and substitute it just as when NO_2 derivs. of C_{10}H_7 are heated with PCl_5 . This mobility is shown by the fact that Friedländer and Littner (C. A. 9, 1335) substituted NO_2 with OH by boiling 1,2- $\text{C}_{10}\text{H}_7(\text{NO}_2)\text{CN}$ with BaCO_3 . It was confirmed by M. and M. by obtaining (c) by the action of ICl on 1,2- $\text{C}_{10}\text{H}_7(\text{NO}_2)\text{N}_2\text{Cl}$. 50 g. $\alpha, \beta\text{-C}_{10}\text{H}_7(\text{NO}_2)\text{NH}_2$ suspended in 250 cc. HCl (d. 1.19) were treated with 500 cc. H_2O which pptd. most of the amine and then with 17 g. NaNO_2 in 200 cc. H_2O at 0° , giving a red-brown liquid which was poured into 41 g. KI in 200 cc. H_2O . This, decolorized with SO_2 , was allowed to stand overnight. The yellow cryst. powder of (c) was filtered and washed with Et_2O and cold H_2O . The wash Et_2O and that used to ext. the mother liquor was filtered, washed with alkali and H_2O , dried with CaCl_2 and evapd., giving the 1,2- $\text{C}_{10}\text{H}_7\text{ClI}$, m. $83\text{--}4^\circ$. 5 g. $\alpha, \beta\text{-C}_{10}\text{H}_7(\text{NO}_2)\text{NH}_2$ were treated with NaNO_2 in HCl. A drop of ICl in I (Bigot, *Ann. chim. phys.* [6] 22, 464(1891)) added to the red-brown soln. ppts. a yellow cryst. powder identical with (c). Also in *Gazz. chim. ital.* 45, II, 200-8(1915).

E. J. WITZERMANN.

The isomerism of erucic and brassidinic and isoerucic acids. III. Their reciprocal cryoscopic behavior. L. MASCARELLI AND G. SANNA. Univ. Cagliari. *Atti accad. Lincei* 24, II, 30-7(1915).—In a previous paper the cryoscopic behavior of these 3 acids in behenic acid (a) was given (C. A. 9, 1761). In this paper the cryoscopic behavior of these 3 acids dissolved reciprocally in each other is described. It was suggested (l. c.) that 1 of these acids has one form and the other 2 the other. It is now thought that erucic acid is the *cis* form and other 2 the *trans*, since the 1st does give solid solns. in behenic acid and since the latter both give solid solns. In erucic acid, brassidinic, isoerucic and behenic acids are cryoscopically normal; in brassidinic acid, erucic acid is normal and isoerucic and behenic acids are abnormal (the latter slightly so); in isoerucic acid erucic is normal and brassidinic acid markedly abnormal and behenic acid somewhat so; in behenic acid erucic acid behaves normally and brassidinic and isoerucic acids abnormally. The observation that behenic acid is not sol. in the solid state in erucic acid and that it does form solid solns. in brassidinic acid agrees with the observation that satd. open chain compds. form mixed crystals with the more stable *trans* modification of the corresponding ethylenic compd. but not with the less stable *cis* form. The f. p. const. of erucic acid lies between 50.5 and 53.6 (av. 52.3) when C_{10}H_8 , dibenzyl, crotonic, elaidinic and BzOH , $p\text{-Br}_2\text{C}_6\text{H}_4$ and Ph_2 were used as solvents; the const. according to Raoult's empirical law should be 209.5. van't Hoff's formula gives 12.13 cal. for the latent heat of fusion of 1 g. mol. erucic acid. The f. p. const. for brassidinic acid is 38.6-44.2 (av. 41.6) in the same solvents; the latent heat of fusion is 17.83 cal. per g. mol. For isoerucic acid the mean f. p. const. in $p\text{-Br}_2\text{C}_6\text{H}_4$, dibenzyl and C_{10}H_8 is 52.54; the calcd. latent heat of fusion is 13.52 cal. per g. mol.

IV. Saturation curves of binary systems. *Ibid* 91-7.—To complete the expts. pre-

viously described (*idem* 1915) and others under way it seemed useful to know the course of the satn. curves obtained by combining erucic, brassidinic, isoerucic and behenic acids in pairs. The existence of 3 acids having the compn. and constitution of erucic acid can only depend on phenomena of isomerism, polymerism or polymorphism. The results of the mol. wt. detns. in previous papers exclude polymerism. The difference between isomerism and polymorphism lies in that the 1st is usually connected with the cryst. state, while the 2nd may also persist in the liquid and gaseous state, so that the study of the solid-liquid equil. may be of value. In detg. the f. p. curve the method of analysis of van Bijlert, for ascertaining whether the compds. were sol. in the solid state and to what extent, could not be applied. Nevertheless the various types of curves could be detd. and classified since the values for mol. wts. at small concns. of the acids dissolved in each other resp. as solvents are known. The f. p. curves show the following: (1) erucic acid with brassidinic, isoerucic and behenic acids, resp., does not give mixed crystals; the curves are made up of 2 branches (on which the pure solvent seps.), meeting in an eutectic pt. (2) isoerucic with brassidinic and brassidinic with behenic give mixed crystals limitedly; the curves have 2 branches (on which the mixed crystals sep.). (3) Isoerucic with behenic acid gives mixed crystals in all proportions; the curve is represented by 1 branch that lies between the m. p. of the 2 components. Omitting erucic acid which occurs in the 1st 3 systems in which mixed crystals are not formed it is uncertain for all the other acids whether they are monomorphic or in part at least dimorphs and show isodimorphism. The types of the curves are the same whether one has 2 isomorphous components or 2 isodimorphic components provided in the 2nd case the mixed crystals may have the cryst. form of the prevalent component. As an example of this the case of formation of mixed crystals of $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$ is discussed. The study of solid solns. of org. compds. has shown that many of them may not show isomorphy in the strict sense but nevertheless can give mixed crystals reciprocally. It is thus quite probable that brassidinic, isoerucic and behenic acids although not being wholly isomorphic may give mixed crystals through phenomena of isopolymorphism. None of the curves shows the formation of compds. which eliminate the possibility that the 3rd isomer may result as an addition product of the other 2. If as has been found with many other org. compds. soly. in the solid state is an indication of similar constitution and configuration erucic acid has a different configuration than all the others. Brassidinic and isoerucic acids since they are sol. in the solid state in behenic acid must have a configuration similar to this acid, which also explains why these 2 acids give mixed crystals. This confirms M.'s previous work but does not explain the existence of 2 *trans* acids having a double bond. Further work is under way. For curves and numerical data see the original. Also in *Gazz. chim. ital.* 45, II, 208-19(1915).

E. J. WITZEMANN.

Indones. I. Synthesis of α -ethyl- β -phenylindone. R. DE FAZI. *Atti accad. Lincei* 24, II, 150-6(1915); *Gazz. chim. ital.* 45, II, 143-51(1915).—The prepn. of α,β -diphenylindone by the action of P_2O_5 on $\text{Ph}_2\text{CCH}(\text{OH})\text{CO}_2\text{H}$ (C. A. 9, 3063) suggested the possibility of obtaining derivs. of indone from cinnamic acid derivs. It was also desired to obtain cinnamic acids with different groups in the α - and β -positions. The syntheses of β -methylcinnamic (Schroeter, C. A. 1, 1988), β -phenylcinnamic (Rupe and Busolt, C. A. 2, 537) and α -methyl- β -phenylcinnamic acid (Rupe, *et al.*, C. A. 8, 1113) suggested a way of prepg. such acids. Treating $\text{EtCHBrCO}_2\text{Et}$ with PhCO_2 and Zn gives $\text{Ph}_2\text{C}(\text{OZnBr})\text{CEtHCO}_2\text{Et}$ which gives $\text{Ph}_2\text{C}(\text{OH})\text{CEtHCO}_2\text{Et}$ (a). (a) with concd. H_2SO_4 in the cold gives a transitory yellow or orange color and then an emerald-green. This green color was noted with β -diphenyllactic, β -phenylcinnamic acids and some derivs. Heyl and Meyer (*Ber.* 28, 2787 (1895)) noted that α,β -diphenylindone gave a green color with concd. H_2SO_4 ; de F. noted the same reaction

for $\text{Ph}_2\text{CCH}(\text{OH})\text{CO}_2\text{H}$ and its derivs. (*l. c.*). From (a) de F. obtained α -ethyl- β -phenylindone which gave the same reaction. Likewise α -methyl- β -diphenyllactic acid (Rupe, *et al.*, *l. c.*) and its α -methyl- β -phenylindone (to be described later) gave the same test with H_2SO_4 . This green color that these acids give with cold H_2SO_4 is a true sign of the formation of indone. Stoermer and Voht (*C. A.* 9, 1757) studied the action of ultraviolet light on the transformation of α -ethyl- and α -methylcinnamic acids into the *allo* form. They found that the stable form does not give the coloration nor the indone but the *allo* form gave the coloration with H_2SO_4 and the indone as well. This result supports the idea that the indones could be obtained by transforming the cinnamic acid into the *allo* form and dehydrating. Bakunin (*Gazz. chim. ital.* 30, I, 355(1900)) mentioned this possibility. Liebermann (*Ber.* 31, 2095(1898)) obtained truxone (the dimer of indone) by treating allocinnamic acid with concd. H_2SO_4 . In the prepn. of α -ethyl- β -phenylindone from (a) by the action of concd. H_2SO_4 in the cold the 1st step was the hydrolysis of the ester to give the free acid, a mol. H_2O was then eliminated to give α -ethyl- β -phenylcinnamic acid and finally a 2nd H_2O was removed between the CO_2H and Ph groups, giving α -ethyl- β -phenylindone (b). This method of synthesis of indones is very simple and gives a good yield: 2 g. (a) give 1 g. (b). 20 g. Ph_2CO in 60 cc. C_6H_6 (dried with Na) + 14 g. $\text{EtCHBrCO}_2\text{Et}$ + 10 g. granulated Zn heated under a condenser (CaCl_2 tube) on the H_2O bath for 2 hrs. was cooled and decompd. with dil. H_2SO_4 . The C_6H_6 soln. was sepd., washed with H_2O and on concg. sepd. tufts of white needles of (a), m. $107-8^\circ$; yield, 20 g. 2 g. (a) were added to 10 cc. concd. H_2SO_4 and after 1 day treated with small pieces of ice with careful cooling in an ice-NaCl bath. The color changes from green gradually to an intense yellow, after which H_2O is added gradually in the same way. The orange-yellow flocks sepd. are collected on a filter and dissolved in EtOH from which sep. orange-yellow shining crystals of (b), m. $92-3^\circ$. 2 g. (b) in 40 cc. EtOH + 2 g. $\text{NH}_2\text{OH.HCl}$ in 10 cc. H_2O boiled 3 hrs. sepd. on cooling α -ethyl- β -phenylindone oxime, gold-yellow needles from EtOH, m. $182-3^\circ$, gives a blood-red color with concd. H_2SO_4 in the cold. 2 g. (b) in 40 cc. EtOH + 2 g. PhNHNH_2 boiled 2 hrs. on the H_2O bath and concd. somewhat seps. on cooling α -ethyl- β -phenylindone phenylhydrazone, intensely yellow prisms from EtOH, m. $136-8^\circ$, gives a red-brown color with cold H_2SO_4 . II. Synthesis of α -methyl- β -phenylindone. *Idem* 343-8.—In continuation of the preceding expts. α -methyl- β -diphenyllactic acid (c) was prepd. according to Rupe, Stieger and Fiedler (*C. A.* 8, 1113): 20 g. Ph_2CO in 60 cc. C_6H_6 treated with 24 g. $\text{MeCHBrCO}_2\text{Et}$ and 7 g. granulated Zn as above with (a), gave 20 g. (c) as white needles, m. $101-2^\circ$. 2 g. (c) in 10 cc. H_2SO_4 treated as with (a) gave flocks of α -methyl- β -phenylindone (d), orange-yellow lamellas from EtOH, m. $86-7^\circ$, identical with that obtained by Rupe, *et al.* (*l. c.*) by the action of SOCl_2 on α -methyl- β -phenylcinnamic acid. (d) gives an emerald color with cold concd. H_2SO_4 ; a red color with cold concd. HNO_3 . One g. (d) in 30 cc. EtOH + 0.5 g. $\text{NH}_2\text{OH.HCl}$ in 5 cc. H_2O boiled 3 hrs. seps. on cooling α -methyl- β -phenylindone oxime, $\text{C}_{15}\text{H}_{15}\text{ON}$, shining yellow-green prisms, m. $199-200^\circ$, gives a blood-red color with cold concd. H_2SO_4 , ruby-red with HNO_3 , sol. in MeOH, EtOH, CHCl_3 and C_6H_6 . 1 g. (d) in 20 cc. EtOH boiled 1 hr. with 1 g. $\text{NH}_2\text{CONHNH}_2\text{HCl}$, seps. on cooling α -methyl- β -phenylindone semicarbazone, $\text{C}_{17}\text{H}_{17}\text{N}_3\text{O}$, rose-orange leaves, m. $219-20^\circ$, gives a blue color with concd. H_2SO_4 , cherry-red with concd. HNO_3 . α -Ethyl- β -phenylindone semicarbazone, $\text{C}_{18}\text{H}_{17}\text{N}_3\text{O}$, orange-yellow tufts of shining needles, m. $198-9^\circ$, was prepd. similarly and gives the same tests with H_2SO_4 and HNO_3 . 1 g. (d) in 50 cc. EtOH treated with 0.40 g. semioxamazide on the H_2O bath 1 hr. sepd. on cooling α -methyl- β -phenylindone semioxamazone, $\text{C}_{18}\text{H}_{15}\text{N}_3\text{O}_2$, as tufts of fine intensely yellow needles, m. $203-5^\circ$, gives a blue color with cold concd. H_2SO_4 , and a cherry-red color with cold concd. HNO_3 .

E. J. WITZEMANN.

A crystallographic study of cuproammonium cyanomethyl- and benzylcyanomethylglutaconimide. FAUSTA BALZAC. Univ. Turin. *Atti accad. Lincei* 24, II, 133-7 (1915).—Guareschi (*Atti accad. Sci. Torino* 1897, 193) described some new cuproammonium compds. of some derivs. of glutaconimide which, written according to Werner's scheme, are as follows: cyanomethylglutaconimide cuproammonia (a), $(C_7H_5N_2O_2)_2[Cu(NH_3)_4] \cdot 2H_2O$; methylcyanomethylglutaconimide cuproammonia, $(C_8H_5N_2O_2)_2[Cu(NH_3)_4] \cdot 4H_2O$; ethylcyanomethylglutaconimide cuproammonia, $(C_9H_5N_2O_2)_2[Cu(NH_3)_4]$; benzylcyanomethylglutaconimide cuproammonia (b), $(C_{10}H_7N_2O_2)_2[Cu(NH_3)_4] \cdot 2H_2O$; cyanophenylglutaconimide cuproammonia, $(C_{10}H_7N_2O_2)_2[Cu(NH_3)_4]$; etc. B. has begun a crystallographic study of these compds. obtained from G. in order to study the morphotropic relations of the compds. of this group depending on the various substituents in the imide as well as the H_2O of crystn. The results with (a) and (b) which differ only in the Bz group are described here. The crystals of (a) belong to the monoclinic system and the prismatic class, $a : b : c = 1.3406 : 1 : 2.0107$, $\beta = 95^\circ 59'$. The crystals of (b) are of the triclinic system; $a : b = 0.7941 : 1$, $\alpha = 94^\circ 42' 6''$, $\beta = 121^\circ 51' 7''$, $\gamma = 69^\circ 58' 15''$. The results with these 2 compds. show that the entrance of the Bz group into the cyanomethylglutaconimide mol. causes a complete change in the cryst. form. The d. is somewhat diminished in the Bz deriv., i. e., there is an increase in the mol. vol. The Bz deriv. is slightly more colored than the other. For details cf. the original.

Formylic and aldehydic derivatives of pyrroles and indoles. LUIGI ALESSANDRI. Florence. *Atti accad. Lincei* 24, II, 194-9 (1915).—This paper is a continuation of A.'s extended and general study of the aldehydes of the pyrrole series. Recently (C. A. 9, 1044) A. showed how from the halogenated compd. of magnesium pyrrole it is possible to obtain α - C_4H_4NCHO (a), in better yield than by Bamberger and Djerdjan's method (*Ber.* 33, 536 (1900)). Although (a) does not show the characteristic reactions of a true aldehyde (such as adding $=NOH$ to give hydroxamic acid), N, α - $C_4H_4NMeCHO$ (b) (Angeli and A., C. A. 9, 1321) seems to give these typical reactions (at least qualitatively). Moreover (a) gives a Na salt which (b) does not; so that these anomalies are explained by giving (a) Formula I. The comparative study of the corresponding

indole derivs. (II) and (III) is not so significant. While α -methylindolealdehyde (II) does not give any hydroxamic acid the N -methyl- α -methylindolealdehyde (III) gives only a trace of a salt that gives a violet color with $FeCl_3$, which A. attributes to the fact that it is an α -substituted aldehyde. Starting with the halogenated compds. of Mg indole by the action of alkyl formates, A. desired to obtain β -indolealdehyde but in this, starting either from α -methylindole or from indole itself, only a small amt. of the aldehydes were obtained. The principal products were a cryst. compd., m. 76.5° , and an oil that crystd. at low temps., isomers of the resp. aldehydes, which boiled with dil. alkali give α -methylindoles and indole, resp., as well as HCO_2H . The compds. are thus probably (IV) and (V). Plancher and Ponti (C. A. 4, 2452) obtained α, α -dimethylpyrrolealdehyde by the action of $CHCl_3$ and KOH on the pyrrole but got poor results in the prepn. of α, β -dimethylpyrrolealdehyde. By the action of alkyl formates on halogen compds. of the corresponding Mg pyrrole A. obtained a little of P. and P.'s aldehyde (VI) (m. $142-3^\circ$) and a larger amt. of the new formylic deriv.

(VII), m. 35°. With α,β -dimethylpyrrole the new aldehyde, m. 89°, is similar to α -pyrrolealdehyde in appearance; oxidized in Me_2CO with KMnO_4 it gives 2,4-dimethylpyrrole-5-carboxylic acid by which its structure was detd. The Na salts of (VI) and (VIII) heated in a sealed tube at 100° with 1 mol. MeI gave the Me derivs., resp., which through analogy with *N*-methyl- α -methylindolealdehyde are substituted at the N atom. *N*-Methyl- α,α -dimethylpyrrolealdehyde (VI), m. 96°, reacts with dihydroxyammonia and gives a cherry-red color with FeCl_3 . *N*-Methyl- α,β -dimethylpyrrolealdehyde was obtained in poor yield as an oil, could not be purified by distn., reacts in part with dihydroxyammonia, gives a brick-red color with FeCl_3 . The study of these compds. will be continued. A. prepd. a considerable quantity of α -pyrrolealdehyde (a), by his own method. A. considered that the liquid product found by Chelintzev and Terentiev (C. A. 9, 88) which they 'thought was a mixt. of pyrrole and alkyl formate might be *N*-formylpyrrole (IX). Its b. p. and other physical properties coincide closely with those of pyrrole but the N content was that of (IX); the sodium salt was obtained and analyzed. Condensed with PhNHOH it gave a compd. $\text{C}_6\text{H}_5\text{NCH:N}(\text{:O})\text{Ph}$, m. 120°, unstable in light like other *N*-Ph ethers of the oxime. In order to prep. *N*-methyl- α -pyrrolealdehyde (b) (C. A. 7, 3972), which is unstable under the conditions under which it was prepd. by F. (a) as the dry Na salt was treated with MeI in the presence of a slight excess of Me_2SO_4 in a sealed tube at 100°. The oil obtained was quite stable, distd. at low pressures and was shown to be identical with F.'s prepn. by means of the phenylhydrazone, m. 123°. (b) also gave an azine, $(\text{C}_6\text{H}_7\text{N:N})_2$, m. 120°, stable and characteristic. (b) reacts easily with dihydroxyammonia and gives the violet-blue color with FeCl_3 but the free hydroxamic acid was not isolated because of lack of material. A. found that α -methylindolealdehyde oxidized in Me_2CO with KMnO_4 gives 2-methylindole-3-carboxylic acid; Plancher (*Atti acad. Lincei* 16, I, 130(1907)) working in alk. soln. obtained only acetylanthranilic acid. It was found that EtNO_2 acting on α -methylindolemagnesium iodide in the presence of Na gave a small yield of 3-nitro-2-methylindole, but the *N*-substituted deriv. may have been formed also. The exptl. details will be published later.

E. J. WITZEMANN.

The crystalline form of α -trinitrotoluene. E. ARTINI. *Atti accad. Lincei* 24, II, 274-9(1915).—A. has undertaken a crystallographic study of the 6 isomeric trinitrotoluenes, at the suggestion of Körner, who with Contardi (cf. C. A. 9, 66, 1478, 3218) isolated the 3 remaining unknown isomers. K. supplied A. with many crystals obtained from several solvents for which the individual data are given. α -Trinitrotoluene belongs to the monoclinic system and the prismatic class, $a : b : c = 1.64047 : 1 : 0.61936$, $\beta = 89^\circ 29' 9''$. Friedländer (*Z. Kryst.* 3, 168(1879)) obtained $a : b : c = 1.6753 : 1 : 0.6354$, $\beta = 90^\circ 0'$, when transformed according to the new orientation. The d. = 1.654, mol. wt. 227.07, mol. vol. 137.29; the values for the relation of the topic axes are $\chi = 8.4181$, $\psi = 5.1315$, $\omega = 3.1782$. 1,3,5-Trinitrobenzene belongs to the rhombic system and bipyramidal class. The d. = 1.688, mol. wt. 213.054 and vol. 126.22. The topic axes $\chi = 8.5504$, $\psi = 5.4064$, $\omega = 3.2757$ bring out the analogy with α -trinitrotoluene. For crystallographic details cf. the original. E. J. WITZEMANN.

The reaction of nitroprusside with thiourea. LIVIO CAMBI. Milan. *Atti accad. Lincei* 24, II, 434-41(1915).—C. recently showed (C. A. 9, 451) that the various color reactions given by ketones with nitroprusside are due to the formation of a complex ion containing the nitrosoketone group. There is a condensation between the NO group of the nitroprusside and ketone like that between alkyl nitrites or NO derivs. in alk. soln. with compds. having a mobile H atom. Of these color reactions of nitroprusside those with sulfides and some alkali mercaptans remain unexplained in which probably $[(\text{CN})_5\text{FeNO}]^- + \text{SR}' \longrightarrow [(\text{CN})_5\text{Fe}^{\text{II}}(\text{NO})^{\text{III}}\text{SR}]^{\text{II}}$ takes place. As an example of this type C. has studied the action of nitroprusside on thiourea which Hof-

mann (*Ann.* 311, 28(1900)) found gave a red-violet salt, $[(\text{CN})_5\text{Fe}^{\text{III}}\text{N}(:\text{O})\text{SC}(\text{NH})\text{NH}_2]\text{Na}_3$. C. observed the ratio 1 Fe:7 N instead of 1 Fe:8 N as in the formula of H. He also observed that N_2 is evolved. From the fact that alkali nitrites in weakly acid media transform $\text{CS}(\text{NH}_2)_2$ into HNCS by way of NH_2CSOH with the evolution of N_2 , C. was led to suppose that the NO group reacts with the NH_2 group to give $[(\text{CN})_5\text{Fe}^{\text{II}}\text{NONHCOSH}]\text{Na}_3$ containing the nitrosothiocarbamic acid group. The aquoferrocyanide indicated was found. Moreover nitro-prusside acting upon $\text{CS}(\text{NH}_2)_2$ in MeOH in the presence of excess of NaOMe gives an orange-yellow salt, which is probably $\text{Na}_7[(\text{CN})_5\text{Fe}^{\text{II}}\text{NONHCOS-Fe}^{\text{II}}(\text{CN})_5]$ and which in H_2O is hydrolyzed to give the red salt of H. Adding soda to a $\text{H}_2\text{O-MeOH}$ soln. of the red salt gave a new orange-yellow brown salt (a), $\text{Na}_3[(\text{CN})_5\text{FeNONCOS}]$, which is the salt of the nitrosothiocarbamic acid present in the complex; this salt is hydrolyzed by H_2O , giving the original red salt. Kept *in vacuo* it decomps. in part in contact with H_2O to give N_2 . The red salt is decomposed by Ag and Hg^{II} salts, giving NO in the ratio 1 NO :1 Fe. The salt (a) similarly treated gives 0.5 NO :1 Fe. On reducing the red salt with Na-Hg $[(\text{CN})_5\text{Fe}^{\text{II}}\text{NH}_2\text{NHCOSH}]\text{Na}_3$ (b) is formed in which the NH_2NH group reduces Hg^{II} salts, HgO , Ag salts and Fehling's soln. in the cold with the evolution of N_2 . $\text{Br-H}_2\text{O}$ added evolved N_2 and gave no nitroprusside, while the red salt gives no N_2 and forms nitroprusside. H. considered the Fe in the red salt as trivalent on the basis of its action with FeCl_3 with which it gives a green color, or ppt. C. found that ferrocyanides containing nitrosoketones give colors. The reaction with alkalis is that of Fe^{II} . Hofmann's salt was at first prepared according to his directions. Modifications of H.'s method were tried: making the components react in alk. carbonate media, in the cold or at $70-80^\circ$, adding NaNO_2 , but the yield was always small. The analysis corresponds closely to 3 Na:1 Fe:1 S:7 N. Using aq. solns. but a strong excess of concd. alkali a change from the red-violet color to orange is noted and the salt (a) is pptd. by adding MeOH in excess; this deliquescent salt freshly prepd. dissolved in H_2O gives the red-violet color in dil. and a red-orange color in concd. solns. A concd. soln. of the red salt cooled to 0° and treated with small amts. of semiliquid Na-Hg gives a golden yellow color gradually and when treated with EtOH seps. (b) as an oil which showed no tendency to cryst.; after washing with EtOH it was dried *in vacuo* and gave green-yellow deliquescent granules sol. in H_2O . The analysis corresponds to (b) except the Na and these variations are explained by the equil.: $\text{Na}_3[(\text{CN})_5\text{FeN}_2\text{H}_2\text{COSH}] + \text{NaOH} \rightleftharpoons \text{Na}_4[(\text{CN})_5\text{FeN}_2\text{H}_2\text{COS}] + \text{H}_2\text{O}$, which would certainly be influenced by varying conditions of concn. (b) is quite unstable; it absorbs O_2 in aq. soln., giving at first a violet color, then greenish and decomps. with sepn. of Fe_3O_4 . Its other reactions were described above. An alc. soln. of nitroprusside was treated with $\text{CS}(\text{NH}_2)_2$ and then NaOMe . The reaction was slow and a dark ochre-colored powder sepd. and N_2 was evolved. After some days the salt $\text{Na}_7\{[(\text{CN})_5\text{Fe}]_2\text{CSNHNO}\} \cdot \text{H}_2\text{O}$ was filtered off and washed with MeOH and Et_2O . This salt is deliquescent; its aq. soln. is dark orange and on standing slowly becomes red-violet; on heating the soln. it decomps. to give Fe_3O_4 , $\text{Fe}(\text{CN})_2$ and the red salt. The acids NONHCOSH and NH_2NHCOSH which enter into these complexes are not known but the corresponding O acids are known; the former as the salt of Thiele, NONKCO_2SK , and the latter as $\text{NH}_2\text{NHCOS}_2\text{H}$.

E. J. WITZEMANN.

Some derivatives of methylvanillin and a new product of condensation. Preliminary note. B. L. VANZETTI. Univ. Padoa. *Atti accad. Lincei* 24, II, 467-70 (1915).—In the study of "isolivile" (Körner, Vanzetti, *C. A.* 6, 1291) V. prepd. veratril and veratroin and V. since has undertaken to prep. veratrylic acid corresponding to benzoic acid. V. has learned that Fritsch (*Ann.* 329, 37(1903)) too was unable to obtain cryst. veratroin. Veratrylic acid (3,4,3',4'-tetramethoxybensilic acid) (a) cannot be obtained

so easily from the keto compds. according to the well-known transposition and oxidation as in the case of benzil, anisil, piperonil, etc., in which the reaction is nearly quant. It seems that the presence of 4 OMe groups renders the mol. inert to this reaction and better adapted to others. Thus benzoin is transformed into benzilic acid by a current of air in the presence of alkali, but veratroin is oxidized quant. to veratril but no farther. Treatment of veratril for 20 hrs. at the b. p. in aq. KOH was unsuccessful. On adding alc. or better with EtOH-KOH a small yield of (a); $C_{19}H_{20}O_7 \cdot H_2O$, was obtained. (a) crystallizes as rosetts of silky needles, m. about 68° , loses H_2O at 105° , browns about 150° . With the hope of finding a more convenient way of prepg. (a) veratric acid was converted into the chloride, m. $70-1^\circ$, which with 1 mol. veratrole + $AlCl_3$ gave [3,4-(MeO) $_2$ C $_6$ H $_3$] $_2$ CO, m. 144.5° ; this by the addition of MeMgI gave diveratrylmethylcarbinol, m. $95-6^\circ$, and diveratrylethylene, which by oxidation gave (a). The compds. will be described in detail elsewhere. The method is not convenient. In treating veratril with KOH at the m. p. mostly veratric acid is formed. The yield of (a) varies much with the temp. and other more complicated transformations cause a dark color and a resinous mass. From this resin by the successive action of solvents an orange-yellow cryst. compound was obtained; it is insol. in H_2O and alk. solns., sol. in org. solvents, sublimes, gives red-brown needles from AcOH, which at $110-20^\circ$ give an orange compd., m. 198° , gives a blue-green color with cold concd. H_2SO_4 which becomes red and on dilg. ppts. a red powder. The compd. is that of veratril with a little less H. In appearance and behavior it is similar to the derivs. of condensed nuclei like phenanthrene or anthracene. It is indifferent to SO_2 and alkali bisulfites. This compd. is to be studied further.

E. J. WITZEMANN.

Process of reduction and oxidation in the terpene group. GUIDO CUSMANO. *Atti accad. Lincei* 24, II, 520-7 (1915).—Previously C. has shown (*C. A.* 8, 1760, 3021) that direct bromination of menthone and tetrahydrocarvone gives (I) and (II) and these

with dil. alks. give "diosphenol" or buccocamphor (VI), a component of the essence of *Diosma cretata*. This result may be explained by assuming that alkali acting on the halogen gives the unsatd. alcs. (III) and (IV) and these by mutual oxidation and re-

duction between the double bond and secondary carbinol give (V) and (VI). C. wished to know if the above interpretation may be verified especially in the transformation of (III) and (IV) into (V). For this purpose it was desired to prep., starting from a halogenated ketoterpene and by eliminating the halogen with alkali, compds. containing a secondary carbinol and a double bond in order to det. if the 2 functions are mutually modified as suggested above. C. used tribromotetrahydrocarvone (a) (Wallach, *Ann.* 286, 127), prepd. from 1,8-dibromotetrahydrocarvone. The position of the 3rd Br was unknown but was thought to be 3. Thus (a) should behave with dil. alkalies like (II). It did not do this. (a) with 2.5% alkali in the cold reacts quant. thus: $C_{10}H_{16}Br_3O + 4NaOH \rightarrow C_{10}H_{17}O_2Na + 3NaBr + H_2O$. $C_{10}H_{17}O_2Na$ is a salt of a mono- CO_2H acid having 2 OH groups and a double bond which with dil. AcOH + PbO_2 gives CO_2 and $Me_2C:CHCH_2CH_2Ac$; the same result is obtained by heating to 250° . In aq. soln. with Pt black this salt absorbs 2 atoms H and the new compd. heated dry gives $Me_2CH.(CH_2)_2Ac$. These facts indicate that the acid is $Me_2C:CHCH_2-$

$\text{CH}_3\text{CMe}(\text{OH})\text{CH}(\text{OH})\text{CO}_2\text{H}$ (*b*) in which the tertiary OH and double bond are derived from Br atoms 1 and 8 in (*a*) and OH in the CO_2H group from Br atom 3. The formula of (*a*) is (VII). The alkali acting on (VII) gives (VIII) which by hydrolysis between

C atoms 3 and 4 gives the aldehyde hydrate, $\text{Me}_2\text{C} : \text{CHCH}_2\text{CH}_2\text{CMe}(\text{OH})\text{CH}(\text{OH})\text{CH}(\text{OH})$, and this by reciprocal oxidation and reduction gives (*b*). (VIII) may also give the tautomer (IX) which by more rapid hydrolysis than (VIII) between C atoms 3 and 4 could give (*b*). This mechanism is more in accord with the mobility of the terpenes. 17 g. powdered (*a*) placed in a 2.5% soln. of 7.2 g. NaOH was completely dissolved after agitating 30 hrs. The neutral soln. was concd. on the H_2O bath until crystn. began; 10 g. $\text{C}_{10}\text{H}_{17}\text{O}_4\text{Na}$ were obtained as shining white lamellas. A similar result is obtained by treating (*a*) with KOH; the K salt is liquid. The Na salt treated with AgNO_3 ppts. the *silver salt*, $\text{C}_{10}\text{H}_{17}\text{O}_4\text{Ag}$; the *barium salt*, $(\text{C}_{10}\text{H}_{17}\text{O}_4)_2\text{Ba} \cdot 2\text{H}_2\text{O}$, was obtained similarly with $\text{Ba}(\text{OH})_2$. Attempts to esterify the acid $\text{C}_{10}\text{H}_{17}\text{O}_4$ by treating its Na salt with a mol. amt. of Me_2SO_4 gave shining white scales containing Na and having an acid reaction corresponding to the acid salt $\text{C}_{10}\text{H}_{17}\text{O}_4\text{Na} \cdot \text{C}_{10}\text{H}_{17}\text{O}_4$. In the prepn. of (*a*) besides the pure solid (*a*) a liquid part was obtained. This treated with NaOH gave a large amt. of $\text{C}_{10}\text{H}_{17}\text{O}_4\text{Na}$ and a *compound*, $\text{C}_{10}\text{H}_{19}\text{O}_4$, shining white needles from dil. EtOH, m. 76° , having the odor of phenol, gives a black-violet color with FeCl_3 , is pptd. by CO_2 from the alk. soln., and is volatile with steam. 2 g. of the Na salt dissolved in 50% AcOH were treated with 2.5 g. PbO_2 with slight warming CO_2 was evolved. On distg. with steam a colorless oil with a banana odor, which treated in H_2O or EtOH with $\text{NH}_2\text{CONHNH}_2$, AcOH gave methylheptenone semicarbazone m. 137° , was obtained identical with the same compd. derived from cineolic anhydride 0.5 g. of the Na salt heated in a small flask with a bare flame gave the same oil and semicarbazone successively. 2 g. of the Na salt in 50 cc. H_2O treated with a few cc. Pt black and agitated with H_2 absorbed 220 cc. at 25° and 764 mm. The mixt. was filtered and concd. and gave a *sodium salt*, $\text{C}_{10}\text{H}_{19}\text{O}_4\text{Na}$, flat, white needles; the *succinic salt*, $\text{C}_{10}\text{H}_{19}\text{O}_4\text{Ag}$, shining white laminas. This Na salt decompd. as above gave methylheptanone, recognized by its semicarbazone, m. 158° .

E. J. WITZMANN

The heat of formation of organic addition compounds. IV. Picrates. B. I. VANZETTI AND V. GAZZABIN. Univ. Padoa. *Atti accad. Lincei* 24, II, 527-32 (1915). —In a preceding paper (C. A. 7, 2222) the heats of combination of picric acid with chemically neutral substances like C_{10}H_8 , eugenol and isosafrol were reported. The values obtained were quite low especially in the case of C_{10}H_8 which has no free valence except the unsatd. valences in the C_6H_3 ring. The heat of formation of the picrate of C_{10}H_8 is only 0.1 cal. per gram mol. This is ascribed to the ethylene bond in these compounds. Additional expts. on the $\text{C}_6\text{H}_4\text{N}$ group have been performed. It is desired to show the difference that exists between combinations of picric acid and tertiary amines ($\text{C}_6\text{H}_4\text{N}$, quinoline, etc.) and the corresponding hydrogenated secondary compds. (piperidine, etc.). Later the expts. are to be extended to the pyrrole group and natural bases (like nicotine, coniine, etc.). The results show that the greatest values were obtained with piperidine as compared with $\text{C}_6\text{H}_4\text{N}$, which was expected from the nature of these 2 bases. $\text{C}_6\text{H}_4\text{N}$ and quinoline give nearly equal values. Tetrahydroquinoline gave very low values contrary to expectation. The heat of formation was detd. with a Thomsen calorimeter by pouring the 2 solns. simultaneously into a satd. soln. of picric acid. The mol. heat of combination of $\text{C}_6\text{H}_4\text{N}$ with picric acid is 13.84 cal.; at a concn. of about 0.22% in H_2O pyridine picrate is about $\frac{2}{3}$ dissociated; at 0.5% in EtOH it

is $\frac{1}{4}$ dissociated. The mol. heat of combination of piperidine with picric acid is 20.56 cal.; at 0.5 to 0.6% in H_2O the picrate is less than 0.5 dissociated into its components; at 0.5 to 2% in 95% EtOH it is $\frac{11}{20}$ combined as the picrate and at 4% concn. it is $\frac{11}{20}$ picrate. The mol. heat of combination of quinoline with picric acid is 13.2 cal.; with tetrahydroquinoline it is 9.9 cal.

E. J. WITZEMANN.

Reaction of esters with magnesium organic compounds. II, III. G. L. STADNIKOV. *J. Russ. Phys. Chem. Soc.* 47, 2037-44, 2115-20(1915).—In a former article (*C. A.* 9, 3052) it was shown that the interaction of esters with iodo-Mg alcoholates of the higher alcs. under certain conditions yields both plain and mixed ethers. It is now shown that the temp. has great influence in this reaction. Thus while under the usual conditions of carrying out Grignard's reaction when the ingredients are mixed slowly and under cooling the product is an alc., if the ester is added all at once to the Mg org. compd. so that the temp. of the mixt. rises quickly the iodo-Mg alcoholate formed in the 1st stage interacts with the ester to give a good yield of ether, together with a little alc. In this way $PhMgBr$ (a), treated under these conditions with $BzOMe$, gives chiefly Ph_3COMe and some Ph_3COH (b). Similarly when to (a) $BzOCH_2Ph$ is added without cooling the product is a mixt. of Ph_3COCH_2Ph (c) and (b). If the last reaction is carried out at 100° the yield of (c) increases, while that of (b) decreases. If an excess of $AcOEt$ is added all at once to $PhMgBr$ (d) without cooling the product consists of 80% of $Ph_3C:CH_2$ (e). When $AcOCH_2Ph$ is added in small portions at a time and with const. cooling to (d) the result is $(PhCH_2)_2O$ and Ph_3MeCOH (f) but no (e). If, however, the mixt. is permitted to get hot the reaction yields $PhCH_2OH$, (f) and (e). Most probably the formation of the unsatd. hydrocarbon $C_{10}H_{18}$ previously obtained by the action of $AcOEt$ on the iodo-Mg alcoholate of terpineol (*C. A.* 9, 3051) is due to the same reaction as yields (e), i. e., at first an acetate of terpineol is produced which reacts with MgI_2 to give $C_{10}H_{17}I$, and this at the elevated temp. interacts with $EtOMgI$ to give $EtOH + C_{10}H_{18} + MgI_2$.

Addition of hydrogen to acetylene derivatives. VI. Hydrogenation of an acetylene alcohol. YU. S. ZAL'KIND. *J. Russ. Phys. Chem. Soc.* 47, 2045-50(1915).—In a former article (*C. A.* 9, 2510) it was shown that with colloidal Pd as catalyzer the hydrogenation of γ -glycols of the C_2H_2 series takes place with a break in the velocity of reduction corresponding to the addition of 2 H, after which the reduction to satd. compd. is much slower, while with Pt black no such breaks occur, the velocity of reduction continually diminishing from the beginning to the end according to the equation for monomol. reactions. In order to see whether other C_2H_2 derivs. behave in the same manner, $Me_3C(OH)C:CPh$ (a) was hydrogenated with Pd as catalyzer. It was found that in this case no break occurs in the velocity of reduction. The product of complete reduction was *dimethyl- β -phenylethylcarbinol*, $Me_3C(OH)CH_2CH_2Ph$, thick liquid of a very agreeable odor, $b_{11} 144^\circ$, $d_4^{20.7} 0.9978$, $d_4^{20.7} 0.9626$, $n_D^{20.7} 1.50775$, is not colored by H_2SO_4 ; *acetate*, $C_{11}H_{18}O_2$, thick, agreeably smelling liquid, $b_{17} 131^\circ$, $d_4^{20.7} 0.9987$, $d_4^{20.7} 0.9831$, $n_D^{20.7} 1.4882$.

Decomposition of lactic acid by killed yeast. V. I. PALLADIN AND D. A. SABININ. *Bull. acad. sci. Petrograd* 1916, 187-94.—For the alc. fermentation of lactic acid (a), P. and S. offer the assumption that it takes place under the influence of AcH with the intermediate formation of pyrroacemic acid (b), which yields CO₂ and continuously regenerates AcH: $\text{MeCH(OH)CO}_2\text{H} + \text{AcH} = \text{AcCO}_2\text{H} + \text{EtOH}$; $\text{AcCO}_2\text{H} = \text{CO}_2 + \text{AcH}$. In order to test this assumption and to have (b) in nascent state, (a) was fermented with zymin, both in presence and absence of (b), and the CO₂, AcH and EtOH produced detd. The results showed that (b) promotes the decompn. of (a) by killed yeast, though to a lesser extent than methylene blue (Harden and Norris, *C. A.* 10, 204). The fermentation of (a) by zymin gives no greater amt. of AcH than is given by (a) alone with zymin. Hence no AcH comes in this reaction from (a). The amt. of alc. in these expts. was considerably smaller as compared with the CO₂ than is the case in normal alc. fermentation. Various possible explanations are suggested for this predominance of CO₂, but none is given preference. It will require further work to clear up this point, as well as definitely to prove the formation of (a) in ordinary alc. fermentation.

The retention of activity by urease and by oxidase after exposure to the temperature of liquid air. JOSEPH S. HEPBURN AND CHARLES B. BAZZONI. *J. Franklin Inst.* 180, 603-5 (1915).—An aq. soln. of urease retained 96.29% of its initial activity after having been kept in a glass container in liquid air for 100 hrs.; the same soln. retained but 44.39% of its initial activity after having been kept at 20° for 100 hrs. After an aq. soln. of cresol tyrosinase (oxidase) had been kept in liquid air for 3.5 hrs. it retained the power to produce a cherry-red color with Witte peptone plus *p*-cresol.

JOSEPH S. HEPBURN

Bubble formation in tonometers. A. URSPRUNG. *Ber. deut. botan. Ges.* 33, 140-53 (1915).—U. discusses the formation of bubbles in tonometers and compares the processes taking place in the cell. By "tonometer" is meant all apparatus which is used to determine the cohesion of fluid. Bubble formation, in the opinion of the author, takes place in the manner described by Gerenz in cases of supersaturated solutions.

B. HOROWITZ

On the effects of various substances (electrolytes, nonelectrolytes, alkaloids, etc.) upon the urease of soy-bean. NAOSUKE ONODERA. Univ. Coll., London. *Biochem. J.* 9, 544-74 (1915).—The inhibitory action of acids on urease is a function of hydrogen-ion concn. and of surface tension. The inhibitory effect of NaOH is due to the hydrogen-ion concn., but that of ammonia has some further factor. The effects of neutral salts are due, to a certain degree, to the alkalinity of metal bases. The effects of alcohols and aldehydes were also studied.

B. H.

Processes of calcification and of ossification. I. Calcium carbonate formation in presence of colloids. L. SABBATANI AND I. SALVIOLI. *Atti r. ist. Veneto* 71, II, 1057-73 (1912).—While the biologic factors producing calcification in bones have been well studied, the chem. and physico-chem. factors are only slightly known. All animal liquids and tissues contain salts of Ca, phosphates and carbonates, but only at certain anatomical points and under detd. physiological and pathological conditions will there be pptn. of carbonates or phosphates of Ca, when the concn. of the constituents of the Ca salts reaches a critical value. Potential causes for fixation and accumulation of

Ca salts in calcification may be (A), chem. combination of Ca salts with organic substances; (B) variations in the nature of the solvent, which is here essentially H_2O ; (C) variations in the product of solubility through increase of concn. of the acid ion (phosphoric, carbonic); (D) increase of concn. of the Ca salt (carbonate or phosphate) in consequence of osmotic work of the tissue, comparable in its effect to an internal secretion; (E) increase in concn. of the Ca salt through positive adsorption, effected by the organic constituents of the tissue. The animal organism in its entirety and with respect to Ca salts in the body and to calcification, represents a 2-phase system, implying a state of stable equil. and a reversibility of the process. From the nature of the union of mineral substances with the organic substance, the deposition of Ca salts in processes of calcification and ossification does not compare with their pptn. in H_2O , but to their pptn. in presence of colloids. Ppts. formed in presence of colloids are not only of diff. cryst. forms than the usual calcite rhombohedron, but are really new products in which the colloids exist intimately united with the mineral substance. The authors first exptd. with egg albumen, which was dild. with 3 vol. H_2O , well shaken and filtered. This soln. was variously dild. and mixed (at 12°) with solns. of Na_2CO_3 and $CaCl_2$ in equimol. proportions. After shaking, a little of the ppt. was collected with a pipet and observed under the microscope. Comparisons were made with ppts. from solns. free from albumen. From albumen solns. the deposits were knot-like, spheroidal, and slightly oval, while albumen-free solns. gave rhombohedral forms, and only exceptionally were rounded forms observed. The same knot-like, spheroidal forms were observed when smaller quantities of albumen were used, with less concn. of the reagents; but with the diminishing quantity of albumen, rhombohedral crystals began to form, which were not of good shape and had blunted angles. The rhombohedral crystals became more well-formed, and increased relatively in numbers with decreasing concn. of albumen, until finally the spheroidal crystals completely disappeared. Similar observations were made using lime H_2O and CO_2 soln. instead of Na_2CO_3 and $CaCl_2$. The albumen must be present at the beginning of the reaction. If it is added only 30 sec. later, the crystals assume the characteristic form of those pptd. in pure H_2O . Similar expts. were made and similar results obtained with ox-blood serum, also with liquid gelatin, though more slowly. By slight change of method the same results were obtained with solid gelatin. Gum arabic and peptone also gave rounded forms. The velocity of the reaction between $CaCl_2$ and Na_2CO_3 is very much less in presence of colloids than in H_2O , but this slowness is not the cause of the rounded, knot-like crystals, because the reaction carried out in concd. glycerol, although exceedingly slow, yields crystals identical with those pptd. in H_2O . Neither viscosity nor high density of the medium are causative factors. Histological observations with high magnification show that the colloid is intimately united with the carbonate in the crystals, and under polarized light they behave exactly like osseous substance. When burned, after washing and drying, they blacken and liberate vapors which have the odor of burnt horn and which change red turnsole paper to blue. An analysis of the sample pptd. in presence of egg albumen (after centrifugal washing and drying *in vacuo* over $CaCl_2$) gave 84.5% $CaCO_3$ and 15.5% organic substance. The rounded crystals suspended in H_2O and treated with $AcOH$ gave CO_2 ; the liquid became transparent but not perfectly limpid, and under the microscope showed rounded forms of the same shape as the original crystals, and similar to the photomicrographic forms obtained on treating bone with acids. No insol. forms are obtained from the rounded crystals from gum arabic and peptone after treating with $AcOH$, because these colloids occur only in the hydrosol state, while the others, occurring in both hydrosol and hydrogel states, change from the 1st to the 2nd on pptn. with $CaCO_3$, and at the time of this change there probably takes place also an adsorption,

causing the intimate union of the protein and the calcareous substance, the adsorption being the more intense, the greater the surface of the adsorbing body and the finer the subdivision.

S. LEVY.

The variations in reaction of the blood of different species as indicated by hemolysis of the red blood cells when treated with acids or alkalis. JAMES G. CUMMING. *J. Infect. Dis.* 18, 151-79(1916).—The chem. index of hemolysis is described as the % of a chem. which will hemolyze a 1% suspension of red cells in a given length of time. The time index is the length of time required by a given concn. of a chem. to produce complete hemolysis of the same amt. of red cells. For the 15 min. hemolytic system there is a marked difference in the chem. requirements (NH_3 , NaOH , HCl) for some species, while the difference is not so marked for others. For this system one of the 3 chem. hemolysins may be of the same % for 2 species. Invariably there appears, however, a difference in the % requirement for either one or both of the other 2 chem. hemolysins. The NH_3 hemolytic time indices divide the animals tested into 4 fairly distinct groupings. The position of the NaOH hemolytic time indices of the different species corresponds closely to that of the NH_3 indices. There is no special arrangement of the HCl time indices for the different species with relation to the alk. indices. By the use of the chem. and hemolytic time indices blood-cell suspensions of different species can be identified with a considerable degree of accuracy. By increasing the % of blood from 1% to 10% a greater variation in the time indices of different species may be found. Alk. hemolysis may be considered to be due to the hydroxyl group, and acid hemolysis due to the H ion. The hemolysis of the red blood cells may be used as an indicator to det. the degree of acidity or alk. of certain solns. As an indicator the cells are affected by the isotonicity of the blood suspension. Hemolysis may be an aid in detg. mol. wts. Alk. hemolysins may be influenced by acids, and acid hemolysins by alkalis. Both acid and alk. hemolysins can be influenced by the neutral-salt content of the suspension. In most of the specimens tested there was shown a distinct variation between the normal and pathological blood of the same species. The time indices in the majority of the latter specimens were increased or decreased in comparison with the normal. It is possible that the variation between the normal and pathological specimens may be accounted for by increased alkalinity or decreased acidity, or by the variation in the neutral-salt content.

Comparative studies in calcification. J. H. MUMMERY. *Proc. Roy. Soc. Med.* 8, *Odontological Sec.* 6-32(1915).—The article includes a description of osmotic growths in colloidal soln. A. H. RAHE.

Urease, an enzyme present in soy beans. K. R. LABBERTE. *Pharm. Weekblad* 52, 1428-40(1915).—L. obtained the active form of the urease by shaking the powder of the soy bean with 10 times its weight of water for 1 hr., centrifuging, and filtering. The action of this ext. on urea solns. was studied by mixing known quantities of the 2 solns., allowing the reaction to proceed for a definite length of time, and titrating the $(\text{NH}_4)_2\text{CO}_3$ formed with standard acid, using dimethylaminoazobenzene as indicator. The results are summarized as follows: (a) The decompn. of urea is not a monomolecular reaction; (b) the av. values of the reaction consts. follow the temp. law of Arrhenius; (c) the reaction velocity is proportional to the enzyme concn.; (d) the catalytic effect of an enzyme soln. is definite and proportional to the amt. of free enzyme; (e) the reaction product retards the reaction; (f) the method can be used for the accurate detn. of urea; (g) acetamide is not hydrolyzed; (h) $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$, $\text{Na}_2\text{SO}_3 \cdot 7\text{H}_2\text{O}$, and H_2S decrease the reaction velocity, H_2S only slightly. Colored turpentine obtained with the help of fat dyes; the use of "yellow glycerol" (Gelbglycerin) as a reagent for wood and cork. M. PLAUT. *Ber. deut. botan. Ges.* 33, 133-9(1915).—A consideration of the prepn. and use of turpentine in biological technic. B. H.

Volumetric estimations of total sulfur and sulfates in small quantities of urine. JACK C. DRUMMOND. King's College, London. *Biochem. J.* 9, 492-507(1915).—D. makes use of the benzidine method. The greatest care must be paid to the details of the technic of filtration, as follows: A 5 cm. funnel fitted into the neck of a 250 cc. filtering flask, carries a small perforated porcelain filtering disk of 1 cm. diameter. A suspension of filter paper pulp is poured into the funnel and sucked dry upon the porcelain disk by means of a filter pump. The layer of filter paper should not be thicker than 1-2 mm. The benzidine sulfate ppt. can now be directly poured on to the filter, and filtered by partial vacuum. Care must be taken to prevent the ppt. at any time from sucking dry upon the filter, as otherwise it will be obtained in a flaky condition and will not be attacked by the alkali during the titration. (Should the flakes appear, dissolve the ppt. in an excess of standard alkali by warming, and titrate the excess of alkali with standard acid.) The pressure is, therefore, greatly released at the moment before the precipitate sucks dry upon the filter. The vessel in which the precipitation has been carried out is then washed out into the funnel with 2 washings of about 2-3 cc. of a satd. soln. of benzidine sulfate in distd. water, and the washings drawn through the filter by gentle suction, again taking care to prevent the ppt. from being sucked dry. The ppt., together with the filter paper and porcelain disk, is transferred by means of a clean glass rod into the vessel in which the pptn. was carried out, and the rod and funnel washed into it with a fine jet of distd. water. The suspension of benzidine sulfate and filter paper is heated to boiling and titrated while hot with 0.2 N KOH. A dil. soln. of phenolphthalein, or a drop or two of a satd. alc. soln. of methyl red, may be used as indicator. A blank should be run upon the reagents. *Inorganic sulfates in urine:* 5 cc. of urine are measured into a 50 cc. beaker, acidified with 0.5 cc. HCl

(1 concd. HCl :3 H_2O), and 20 cc. of the benzidine reagent are then added. Allow the ppt. to settle for 5 min. and filter upon a small filter-paper pulp as described above. Transfer the ppt. to the original beaker, and titrate at the boiling pt. with 0.2 N KOH . Even 2 cc. of urine may be used for an estn. *Total sulfates*: 5 cc. urine are measured into a 25 cc. wide-mouthed Erlenmeyer flask, and 0.5 cc. HCl (1 concd. HCl :3 H_2O) is added. A small glass funnel inserted in the neck of the Erlenmeyer acts as a reflux trap to prevent spurting and undue concn. of liquid. Boil the liquid gently on a sand bath for 30-40 minutes. Keep the volume of liquid fairly const. Now cool, wash the funnel and neck of flask with a fine jet of distd. water, and add 20 cc. of the benzidine reagent. Allow the ppt. to settle for 5 min. and proceed as with inorg. sulfates. *Total sulfur*: 2 cc. of urine are measured into a 6 cm. porcelain evapg. dish, 0.5 cc. of Benedict's reagent is added, and the fluid evapd. gently to dryness on a water-bath. Ignite the residue by the use of a Barthel alc. burner. Cool, and add 1 cc. of 1 in 4 HCl . Cover the dish with a clock-glass, and warm upon the water-bath until the residue is entirely in soln. Should evapn. to dryness occur before soln. is complete, add 1 cc. of acid and continue warming. Wash the cover into the dish, and gently evap. the contents to dryness. Add 1 cc. of distd. water, and transfer the contents to a 25 cc. beaker. Add 10 cc. of the benzidine reagent. From here proceed as with inorganic sulfates. D. obtains good results with his method (many examples given).

B. HOROWITZ.

New method for the preparation of plant globulins. GEORGE REEVES. Imperial Coll. of Science, London. *Biochem. J.* 9, 508-10(1915).—R. makes use of Schryver's observation (*C. A.* 8, 182) that the globulins are much more sol. in solutions of those salts which lower the surface tension of water than they are in NaCl soln. The bulk of material employed is thereby reduced. *Prepn. of edestin from hemp-seed*: The seed is ground and extd. with light petroleum. It is filtered, washed with petroleum, and air-dried. The husks are then removed by sifting through course muslin. 500 g. of material thus prepd. are mixed with 500 cc. 0.5 N Na benzoate soln. (corresponding to about 7%). After standing for 30 min. enough torn blotting paper is pressed into the mass to make it appear almost dry. The whole is wrapped round with filter paper, placed in a Buchner press, and submitted to high pressure. The residual mass is again extd. with 500 cc. of the benzoate soln. and the above operation repeated. The combined exts. are poured into 10 l. of water, and allowed to stand overnight. The clear liquid is decanted off, and the creamy paste at the bottom is centrifuged. The edestin, which seps. as a powder, is washed twice with water, once with 95% alc., once with abs. alc., and twice with dry ether. It is then quickly transferred to a vacuum desiccator. The product thus obtained is almost entirely sol. in 10% NaCl soln., and from this it can be obtained in cryst. form in the usual way. 450 g. of the sifted meal yield 130 g. crude edestin (vacuum-dried). In a similar manner excelsin from Brazil nuts and legumin and vicillin from horse-beans were prepd.

B. HOROWITZ.

The preparation of collodion membranes of differential permeability. WILLIAM BROWN. Imperial Coll. of Sci. and Technology, London. *Biochem. J.* 9, 591-617(1915); cf. *C. A.* 10, 207.—Collodion membranes are completely air-dried, whereby they become highly impermeable; they are then placed in solns. of alc. and water for a suitable time. When subsequently washed in water these membranes show a permeability which decreases regularly with the strength of the alc. employed. *Method of preparing air-dried membranes*: An 8% soln. of Schering's celloidin in a mixt. of equal parts (by vol.) of abs. alc. and ether is used. The membranes are formed on the outside of a test tube (1 cm. diameter). The latter is dipped in the collodion soln. to a depth of 8-10 cm., drained for a few seconds, and placed in a vertical position inside an inverted conical flask ($\frac{1}{2}$ l. capacity), being held by an ordinary cork which fits the neck of the

flask. By manipulation of the tube after insertion into the flask the length of the membrane can be increased. The tube is allowed to drain for five minutes after which it is withdrawn and *immediately* immersed in water. After about one minute the membrane is stripped off by eversion. For this purpose use is made of the "runnels" of collodion, which have by now become solidified. These on being cut across serve as handles in pulling the membrane off. The membrane is trimmed, washed in water and dried at laboratory temp. *Alcohol treatment:* The membrane is soaked in the alc. mixt. for 24 hrs. at 20°. It is then transferred to distd. water and washed for one day. The diffusive capacity of any substance through collodion may be specified in terms of the alc. strength required to produce the membrane which just prevents its passage. This is termed the "alcohol index" of the substance.

B. HOROWITZ.

Fractionation of the phosphotungstic acid precipitate with acetone as a useful method for the preparation of the vitamine fraction from yeast. CASIMIR FUNK. *Biochem. Bull.* 5, 1-16(1916).—"The phosphotungstate ppt. from alc. ext. of yeast can be divided by means of Me_2CO into two fractions: A small insol. fraction, which contains the bulk of the vitamine; and a large sol. one, which is totally inactive." In order to avoid the use of alkali, which has a tendency to destroy vitamine, the phosphotungstates were decomposed with $\text{Pb}(\text{OAc})_2$ instead of baryta; very clear solns. are obtained which facilitate further purification. A crude sepn. of the phosphotungstate ppt. into 4 sol. fractions can be effected by using 25, 100, 50 and 75% Me_2CO solns. in this order. A fifth insol. fraction remains, representing about 13% of the total ppt.

A. P. LOTHROP.

The bromine and iodine compounds of hexamethylenetetramine. K. SUGIURA AND K. G. FALK. Harriman Research Lab., N. Y. *Biochem. Bull.* 5, 17-21(1916).—A study of the compds. which $(\text{CH}_2)_6\text{N}_4$ forms with Br and I has led to the development of a simple quant. method for its estn. based upon the formation of the tetraiodide. To 50 cc. of soln. free from proteins or similar substances pptd. by I, add from a buret with stirring an alc. I soln. contg. 3.6 g. of I in 100 cc. of 95% alc. If $(\text{CH}_2)_6\text{N}_4$ is present a brownish yellow ppt. is formed which changes to reddish and finally to dark brown. About 20% excess of I is advisable (5-8 cc. required as a rule). Allow to stand for 10 min. with occasional stirring and filter with suction through an asbestos mat in a Gooch crucible. Refilter through the same mat once. Wash the ppt. 5-10 times with cold H_2O . Transfer the ppt. and crucible to a beaker, add 50 cc. of H_2O and 3 cc. of glacial AcOH and titrate with 0.04 M $\text{Na}_2\text{S}_2\text{O}_3$ soln., adding starch soln. near the end point. 1 cc. 0.04 M $\text{Na}_2\text{S}_2\text{O}_3$ soln. is equiv. to 1.4 mg. of $(\text{CH}_2)_6\text{N}_4$. If the liquid contains protein, such as albumin in urine, add an equal vol. of MeOH , allow to stand 1-2 hrs., filter by decantation through folded filter paper and evap. to $\frac{1}{2}$ the vol. in an air current or under diminished pressure. Add I soln. and proceed as described. The error in aq. soln. is at most 15%, usually much less. In urines, a compensation of errors apparently occurs and the results are accurate within 5%, but are satisfactory for the detn. of the amts. of $(\text{CH}_2)_6\text{N}_4$ eliminated by the body under various conditions.

A. P. LOTHROP.

Respiratory chamber for small animals. A. C. KOLLS AND A. S. LOEVENHART. Univ. Wisconsin. *Am. J. Physiol.* 39, 67-76(1915).—Description of a respiration chamber ($90 \times 90 \times 45$ cm.) with a closed ventilating system with automatic control in which animals may be kept a week or more in a given atm. of O and N. A smaller chamber ($50 \times 50 \times 38$ cm.) is designed for expts. at reduced or increased pressures.

J. F. LYMAN.

Method of bringing a small quantity of blood into equilibrium with a given gas. "Microaerotonometer." T. KATO. Cambridge. *J. Physiol.* 50, 37-41(1915).—App. is described suitable for exposing small amts. (0.1 cc.) of blood to gases for the

purpose of establishing equil. between the two. A gas holder suitable for storing mixts. of gases of known compn. to be used with the above app. is also described.

J. F. LYMAN.

The bacteria of gangrenous wounds. H. R. DEAN, Univ. Manchester, and T. B. MOVAT, Sheffield. *Brit. Med. J.* 1916, I, 77-83.—A new medium for the cultivation of anaerobic bacteria is described. The yolk of one egg is shaken with glass beads, 300 cc. of distd. water added, the shaking repeated, and the whole kept at the boiling point for $\frac{1}{2}$ hr. The mixt. is shaken during the whole period of heating. The medium is particularly adapted to the cultivation of *B. edematis maligni*. A. H. RAHE.

New reaction of urine. A. BACH. *Compt. rend.* 162, 353-4(1916); cf. C. A. 5, 2258, 3859; 6, 495, 872.—This test depends on the reducing action upon nitrates of an enzyme when in the presence of a coenzyme existing in urine. Separately these enzymes exert no reducing action. An approx. detn. is carried out by adding to 3 cc. of fresh urine, 2 cc. of fresh milk and 0.2 g. NaNO_3 (free from nitrite) and allowing to stand 20 min. at 60° . A control is run with the same proportion of urine and milk but without the NaNO_3 . At the end of 20 min., to each is added 5 cc. of Ilosvay reagent (a mixt. of sulfanilic acid and α -naphthylamine in AcOH) when the contents of the tube containing the nitrate become more or less red while the control remains unchanged. Upon adding to the control drop by drop a measured amt. of standard NaNO_2 until the color of the test is matched, the amt. of nitrite may be detd. For more accurate detns. 15 cc. of urine, 10 cc. of milk and 1 g. of NaNO_2 are mixed. At the termination of the reaction 0.5 g. finely pulverized $\text{PbOH}(\text{C}_2\text{H}_3\text{O}_2)$ is added, the mixt. agitated, filtered through a dry filter and the nitrite detd. in 20 cc. of the filtrate as in the sanitary analysis of water. Expts. show that 1 cc. of urine in the presence of milk can reduce from 0.01 to 0.05 g. of N_2O_4 . Urine previously boiled gives the same result as normal urine. With boiled milk and nitrate or fresh milk without nitrate the reaction is not produced. Blood serum aseptically obtained does not reduce nitrates in the presence of milk, but serum subjected to the action of bacteria, or even of a pure culture (diphtheric toxin) gives an intense reaction. L. W. RIGGS.

Capillary test for acidity in the stomach. S. ORRILL. *Hygiea* 77, No. 21(1915); *J. Am. Med. Assoc.* 66, 392.—O. repeated the work of Holmgren (cf. C. A. 5, 1616) and found that the results which differed from those of H. were due to the drying out of the blotting paper which had been used. It had lost much of its adsorbing power and the figures obtained were too high. The findings after 5 min. were taken as the standard. L. W. RIGGS.

Occult bleeding in differential diagnosis. C. SALVINI. *Riforma medica* 31, No. 49(1915); *J. Am. Med. Assoc.* 66, 463.—In an investigation of various technics for the detection of invisible blood in stomach contents or stools the benzidine method and Ganassini's eosin reaction (cf. C. A. 9, 3265) gave the clearest responses, being sufficiently sensitive down to 1 in 15000 for all practical purposes. Only findings in the first 30 min. are reliable. L. W. RIGGS.

Measurement of oxidation in sea-urchin egg. L. V. HEILBRUN. *Science* 42, 615-6(1915).—The errors due to change of I concn., in the methods of Winkler, Ridel and Stewart, and Warburg and Siebeck are pointed out and the following procedure suggested: The eggs are inclosed in celloidin tubes of about 10 cc. capacity and narrow bore to fit into 300 cc. bottles previously filled with sea-water. At the conclusion of the expt. the tube containing the eggs is taken out and the bottle completely filled with sea-water of known O content and tested for O by the Winkler method. Iodine absorbing substances normally given off by *Arbacia* eggs are colloidal and do not pass through the walls of the celloidin tube. The amt. of I in the sea-water therefore re-

mains constant and does not interfere with the detn. of O. H.'s method cannot be used without modification for the measurement of oxidations during cleavage, because the eggs are too tightly packed. The results show that partial or complete cytolysis produced by dil. sea-water causes a decrease of oxidations.

L. W. RIGGS.

Estimation of inorganic phosphorus in plant and animal substances (FORBES) 7.

C. BACTERIOLOGY.

ERNEST D. CLARK.

The bactericidal power of serum after the administration of salvarsan or neosalvarsan. S. R. DOUGLAS AND L. COLEBROOK. London. *Lancet* 1916, I, 181-3.—Salvarsan and neosalvarsan in aq. solns. possess a very distinct bactericidal power against staphylococci in dilns. of 1-6000. When the solvent consists largely of blood or serum this power is slightly diminished. The bactericidal power of these two preps. appears to be practically the same. The administration of neosalvarsan in ordinary doses renders the serum markedly bactericidal. This condition lasts but a short time and seems to reach its max. about 1 hr. after the administration of the drug, diminishing rapidly in the 3rd and 4th hrs. Heating the serum to 60° for 10-20 min. has no deleterious effect on the bactericidal power, showing that it is not in any way due to development of immune bodies in the serum. Salvarsan gave practically no demonstrable bactericidal power to the patient's serum when ordinary therapeutic doses were administered.

GEO. T. CALDWELL.

The gum-disease of sugar cane, caused by the *Bacterium vascularum* Cobb. J. GROENEWEGE. Pasoeroean. *Med. Proef. Java-Suikerind.* 5, 29-124 (1914); *Chem. Zentr.* 1915, I, 1128.—After a thorough description of the gum-disease produced by the *Bacterium vascularum* Cobb., G. discusses the morphology and culture of the bacterium. Cultures on peptone-bouillon and gelatin are colorless; on agar they are ochre-yellow. They cause coagulation of milk with reaction at first neutral, later alk.; there is slow peptonization of the coagulum. Nitrates are not reduced and sugars are not fermented. The indole formation is slight. With NH₄ tartrate as C- and N-source there is no growth. The virulence toward cane sugar is not diminished after a year. Indican is decomposed; urea is not. There is weak H₂S formation. The bacterium is extremely aerobic. Diastase and invertase are not formed.

P. M. GIESY.

Studies in antiseptics. II. "Chloramine," its preparation, properties and use. H. D. DAKIN, J. B. COHEN AND J. KENYON. *Brit. Med. J.* 1916, I, 160-2.—Sodium *p*-toluenesulfonchloroamide (chloramine) was chosen as an antiseptic because of its N-Cl linkage. This type of linkage is assumed to take place when hypochlorites act upon protein. A table showing germicidal action in serum and water is given.

A. H. RAHE.

Vitality of the cholera vibrio in the water of New York Bay. A. J. GELARIE. Quarantine Laboratory, New York. *Med. Record* 89, 236-9 (1916).—The survival of cholera organisms in water depends upon the particular strain employed, the type of water, the number of bacteria seeded and other factors. The vibrios lived in native bay water 7-47 days and in sterilized bay water for 285 days. In sterile tap water they survived 1-18 days; in native tap water 1-3 days. In competition with water bacteria the life of the vibrios is short. Prolonged exposure to native bay water (44 days) caused an alteration in the form of the organisms and rendered them inagglutinable. After repeated transfer of such altered organisms from peptone water to agar and *vice versa* they reassumed their original forms and could again be agglutinated.

A. H. R.

Two unusual strains of diphtheroid bacilli. RALPH R. MELLON. Ann Arbor. *Med. Record* 89, 240-1 (1916).—One of the organisms described showed extreme pleomorphism, alternating from bacillary to streptococcal form. It fermented, without

gas production, dextrose, lactose, dextrin, glycerol, sucrose, salicin, maltose and inulin. The other strain was a strict anaerobe, showing only ordinary pleomorphism. Both strains were pathogenic for rabbits.

A. H. RAHR.

Action of ozone on microorganisms and artificial substrates, as shown by ozone treatment in the cold storage of meat. R. HEISE. *Arb. hies. Gesundh.* 50, 204-31 (1915).—The results of this study are shown in 13 tables, 5 figures, and over 35 references to literature. The following summary is given: The bactericidal action of impure or purified ozone appears only at the surface of the nutritive medium and in case the ozonizing follows soon after the inoculation. If the development of the culture is retarded by low temp., ozone exerts its bactericidal action the same as shortly after inoculation. If the culture had developed colonies no efficient action of the ozone occurred. Repeated ozonizing produced no change other than morphological differences according as impure or pure ozone was used. If the surface of the nutritive gelatin is ozonized before inoculation with a culture of *B. coli*, the growth is notably retarded, the action being stronger for impure than for pure ozone. The precise manner in which the ozone affects the nutritive matter and the role of the oxides of N is not detd. The results of this lab. study do not contradict the experience from the use of ozone in the cold storage of meat.

L. W. RIGGS.

Action of antiseptics on pus. P. DELBERT. *Compt. rend.* 162, 36-8 (1916).—The pus was stirred to a homogeneous condition and taken into pipets with little more than double the vol. of the antiseptic soln. to be studied. The pipets were then sealed and kept in a closet under the same conditions as a control pipet containing untreated pus. After 24 hrs. a sowing and a culture were made from each pipet. Although these conditions were very favorable to the action of antiseptics, sterilization was the exception. In many cases the bouillon inoculation from pus cultures in contact with the antiseptic gave a larger crop than inoculation from the control tubes, especially if hypochlorite was used as the antiseptic agent. This agrees with the observation that the number of bacteria may increase in wounds dressed with antiseptics. Phenol, in concns. of 2 to 100, proved the best antiseptic though one of the weakest germicides. Other antiseptics tried were Et_2O , "sublimate," Labarraque's soln., and Dakin's soln. D. suggests the following explanation: The hypochlorite combines with certain elements of the pus in a manner to form products favorable to bacterial growth. These products, which are called "intermediates," are formed before the antiseptic acts upon the bacteria and cause a suppression of the antiseptic; and by the splitting of the protein mol. the latter is more easily utilized by the bacteria.

L. W. RIGGS.

Rapid method of counting living bacteria in milk and other richly seeded materials. W. D. FROST. Univ. Wis., Madison. *J. Am. Med. Assoc.* 66, 989-90 (1916).—One-twentieth cc. of milk is mixed with standard nutrient agar and spread over a definite area of a sterile glass slide. When the agar is hard this small plate culture is placed in an incubator for 6 hrs. under conditions which prevent evapn. It is then dried, given a preliminary treatment to prevent the agar from firmly binding the stain, stained, decolorized and cleared. When this plate culture is examd. under the microscope the colonies appear highly colored on a colorless or slightly colored background, and can readily be counted. Very complete directions, which are too long to be abstracted, are given in the original paper. These directions make special reference to the counting of colonies and calcg. the number of bacteria per cc.

L. W. RIGGS.

Magnesium hypochlorite as a disinfectant. C. MAYER. *Paris médical* 6, No. 8 (1916); *J. Am. Med. Assoc.* 66, 988.—The advantages claimed for $\text{Mg}(\text{ClO})_2$ are that it is less caustic than NaClO and is not expensive. It is prepd. by mixing 2 liters of water containing 190 g. of MgSO_4 with 2 liters of water into which 100 g. of CaOCl_2 have

been stirred. The ppt. of CaSO_4 is allowed to settle and the clear liquid used. This fluid is tolerated perfectly by the tissues so that it can be applied freely.

L. W. RIGGS.

Factors involved in germicidal effect of freezing and low temperatures. C. M. HILLIARD, C. TOROSSIAN AND R. P. STONE. Simmons Coll. *Science* 42, 770-1(1915).—Different species of bacteria were differently affected by freezing; thus 99% of 24 hr. old cultures of *B. coli* were killed by freezing in tap water or in distd. water in 3 hrs., while with a culture of *B. subtilis*, presumably free from spores, the reduction, though not uniform, was seldom over 80%. Three strains of *B. coli* showed no appreciable difference in relation to the germicidal action of freezing. Intermittent freezing and thawing had but slightly greater influence upon *B. coli* than sustained freezing for the same length of time. A temp. of -15° was much more fatal to *B. coli* than -2° , while in control tubes kept at $+0.5^\circ$ for 3 hrs. seldom over 40% of the bacteria were killed. Cream containing 30% fat exerts a striking protection to bacteria whether the freezing be continuous or intermittent.

L. W. RIGGS.

D. BOTANY.

CARL L. ALSBERG.

Physiology of the intake of material by the living plant cell. III. Influence of neutral salts and some nonelectrolytes on the toxic action of alcohols on plant cells. HELENE NOTHMANN-ZUCKERKANDL. *Intern. Z. physik.-chem. Biol.* 2, 19-41(1914); *J. Chem. Soc.* 108, I, 199-200.—The exosmosis occurring when leaves of plants (*Echeveria*, *Saxifraga sarmentosa*, and *Tradescantia discolor*) are immersed in aq. solns. of the lower alcs. increases if neutral salts are also added. Those salts which, in aq. soln., produce the greatest exosmosis have the greatest supplementary action on the osmosis caused by the alc. solns. It is probable that the observed augmentation on the addition of a salt is not due to an altered soly. of the alc., but to a summation of the separate actions of the 2 substances, alc. and salt. In the presence of butyl and higher alcs., salts react usually in such a way as to reduce the exosmotic effect; but sometimes the action is so slight in comparison with the toxicity of the added salt that it is unobservable. The antagonism between butyl alc. and salts is explained by the assumption that they enter the cell by the same path, and when both are present, each obstructs the passage of the other. Plasmolysis expts., showing that the concn. limit of van't Hoff's soln. which just produces plasmolysis is lowered by butyl alc., confirm this view. The author draws the conclusion that the hydrocolloids of the plasma must constitute the only path by which materials enter the plant cell. Tannic and aspartic acids and peptone increase the action of the various alcs., while glycine, tyrosine, sucrose, and maltose are inactive. The osmotic power of nonelectrolytes, as well as of salts, is therefore of secondary importance to the lyotropic influence in producing effects on plant cells.

E. J. C.

Injurious root secretions. D. PRIANISHNIKOV. *Rev. gén. botan.* 25, 563-82 (1914); *J. Chem. Soc.* 106, I, 1208-9.—The results of expts. in which etiolated wheat plants were grown successively in the same distd. water showed no reduction in the yield; under these conditions no substance toxic to wheat seems to be secreted by the roots of wheat. In sand and soil-culture expts. it was found, however, that the yields of subsequent crops were considerably reduced, according to the plants grown, not only when the same plant was grown 2 or 3 times in succession, but with different plants. The reduction in yield was much greater when the roots of the first plant were left in than when they were removed. Oats grown in an ext. of black soil gave a very small yield, while normal growth was obtained when the ext. was filtered through charcoal. When the ext. was distd., and both the distillate and the residue employed as culture

solns., the former produced a normal growth and the latter a much smaller yield; the difference was still more marked when the distn. was conducted under reduced pressure. The conclusion is drawn that roots contain a substance which is toxic both to the same and to other plants. It is suggested that one cause of the reduced yield of a second growth may be the increased alkalinity, which would be greater when the first crop is removed during early periods of growth, and varies according to the plant grown. On the other hand, alkalinity is not removed by charcoal, which in some cases raised the yield to its original amt. The expts. referred to form part of a research by Peritourine (*Ann. Inst. Agron. Moscow* 1913, No. 4).
E. J. C.

Enzymes of apples and their relation to the ripening process. R. W. THATCHER. Univ. Minn. *J. Agr. Res.* 5, 103-16(1915).—Ripening is defined as the change taking place between the cessation of growth and the disintegration of the tissue until it becomes mushy. Attempts to surround individual apples with films to prevent gaseous exchange were not successful. The method used was to seal the apples in atmospheres of different gases under as nearly sterile conditions as possible. Gases used were air, H, N, O, CO₂, and SO₂. Only CO₂ and SO₂ seemed to retard ripening. In prepg. pulp for sepn. of the enzymes, slices of apple were treated with acetone-ether, dried and powdered or the pulp ground with quartz sand. These methods yielded active exts. The oxidases were the only enzymes which produced changes in the carbohydrates during ripening. The presence of small amts. of esterase and protease indicates the possibility of hydrolytic decompn. of the small amts. of essential oil and protein present.

R. O. E. D.

The poisonous forms of *Phaseolus lunatus* (the lima bean). W. R. DUNLOP. *West Indian Bull.* 15, 29-35(1915).—The poisonous principle is HCN. The dark purple or black bean (the Java bean) is dangerously poisonous; the creamy-white lima bean is perfectly wholesome.

W. H. FRY.

A chemical peculiarity of the dimorphic anthers of *Lagerstroemia indica*, with a suggestion as to its ecological significance. J. A. HARRIS. *Ann. Botany* 28, 499-507(1914).—In *L. indica* the stamens are dimorphic. Those of the outer whorl are larger than those of the central yellow group. H. maintains that the differentiation is due to chemical phenomena.

B. H.

Filtration and lifting power (Hebungskraft). A. URSPRUNG. *Ber. botan. Ges.* 33, 112-7(1915).—Observations concerning the lifting power of leaves, etc.

B. H.

Several new instances of the action of nitrogenous compounds initiating germination on seeds sensitive to light. G. GASSNER. *Ber. botan. Ges.* 33, 217-32(1915).

B. H.

The urease of the soy bean and its "co-enzyme." NAOSUKE ONODERA. Univ. Coll., London. *Biochem. J.* 9, 575-90(1915).—A 1.5% urease soln. lost its activity by 5 days' dialysis, 5 cc. of this dialyzed urease developing only 0.08 cc. 0.1 N NH₃, while 5 cc. of the control urease, even 3 times diluted, hydrolyzed almost all the urea present in nearly the same time. The addition of 0.5 and 1 cc. of 0.5% soln. of fresh urease revived the lost action markedly, the amt. of NH₃ produced by the mixture being much greater than the sum of the amts. produced by the dialyzed and the fresh urease used separately. The "co-enzyme" is not an inorganic salt, and is destroyed by ether. It probably consists of 2 groups of components, one of which is dialyzable and the other non-dialyzable. The inhibitory effects of heat, acid and alkalis are exerted upon the co-enzyme, but not upon the urease proper. In germination, urease accumulates in the germs of the soy beans in large proportion, but free co-enzyme is absent. Ox serum, though it has an accelerating influence on urease action, contains no co-enzyme.

B. HOROWITZ.

Relation between osmotic pressure and regulation of stomata. W. S. ILJIN. *Bot. Centrbl., Beihefte* 32, 15-35(1914).—Stomatal regulation, which is related to transpiration conditions, shows a close relation to change in starch content, and this again shows a close relation to variations in osmotic pressure. B. H.

Increased carbon dioxide concentration in relation to transpiration and development in plants. N. KISSELEW. *Bot. Centrbl., Beihefte* 32, 86-96(1914).—An increase of carbon dioxide supplied to plants considerably accelerates development. B. H.

Nitrites in plants. K. ASO AND T. SEKINE. *Bot. Centrbl., Beihefte* 32, 146-7(1914).—Nitrites are present in the shoot-like buds of *Sagittaria sagittifolia*. These nitrites may be produced by the oxidation of amino acids, or the reduction of nitrates. B. HOROWITZ.

Growth and colloid hydration in cacti. E. R. LONG. *Bot. Gaz.* 59, 491-7(1915).—Hydrochloric and malic acids inhibited growth and hydration in *Opuntia blakeana*. NaOH was not so constant in its action as the acids. B. HOROWITZ.

Lycopin and its relation to chlorophyll. W. LUBIMENKO. *Rev. gén. botan.* 25, 475-93(1914).—The formation of lycopin and the decomposition of chlorophyll in plants go on simultaneously. L. regards the oxidation of chlorophyll as giving rise to lycopin and lycopinoids. B. HOROWITZ.

Biochemical investigation of saponins. MARIE KORSKOFF. *Rev. gén. botan.* 26, 225-44(1914).—This deals with the occurrence, distribution, and role of saponin in *Saponaria officinalis* and *Agrostemma githago*. In the course of germination the amt. of saponin does not diminish. K. regards this as showing that the saponin is not utilized as a food reserve. B. HOROWITZ.

Absorption and excretion of electrolytes by *Lupinus albus* in dilute simple solutions of nutrient salts. R. H. TRUE AND H. H. BARTLETT. *Science* 41, 180-1(1915).—The absorption of ions from solns. was measured by changes in electrical cond. K phosphate and KCl behaved like distd. water; K_2SO_4 , KNO_3 , and NaCl showed slight absorption; $Ca(NO_3)_2$ and $CaSO_4$ showed decided absorption. B. HOROWITZ.

Influence of acids, alkalies and alkali salts on the growth of rice plants. K. MIYAKE. *Trans. Sapporo Nat. Hist. Soc.* 5, 91-5(1913); *Bot. Centrbl.* 126, 588(1914).—The hydrogen ion is more injurious than the sodium ion, and the latter more so than that of potassium. The OH ion is more injurious than either the SO_4 or Cl ion. B. H.

The complex carbohydrates and forms of sulfur in marine algae of the Pacific Coast. D. R. HOAGLAND AND L. L. LIEB. *Cal. Agr. Expt. Station, Berkeley. J. Biol. Chem.* 23, 287-97(1915); cf. *C. A.* 9, 1525.—Marine algae do not contain simple carbohydrates or easily hydrolyzed polysaccharides. Starch is not present and only minor amts. of cellulose. The most frequently occurring carbohydrates are pentosans, galactans, levulans and methylpentosans. H. and L. describe in detail the physical and chem. properties of several complex polysaccharides obtained from *Macrocystis pyrifera* and *Iridaea laminarioides*. From the acid-precipitable complex known as "algin" a pentosazone was prepared with a m. p. of $154-5^\circ$, similar in many of its properties to *l*-xylose phenylosazone. In the alc.-insol. carbohydrate fraction of *Macrocystis pyrifera* a methylpentose, having the properties of fucose, was isolated; a similar fraction from *Iridaea laminarioides* yielded only galactose. Estimations were made of the various forms of S in *Ulva fasciata* which contains 4.44% of total S, of which 3.21% is sol. and 2.85% exists as sol. sulfates. Marine algae in general have a high S content. A. P. LOTHROP.

Significance of oblique incidence of light for helio-perception of parallelotropotrophic organs. K. NOACK. Freiburg i/B. *Inaug. Diss. Freiburg i/B.* 1914, 79 pp.; *Zentr. Biochem. Biophys.* 18, 303-4(1915).—Phototropic excitation is dependent (1) upon

the amt. of incident light and (2) upon the angle of incidence. These results do not sustain Blaauw's hypothesis of a simple photochem. action of light. H. S. PAINE.

Plant chemistry. P. Q. KEEGAN. *Chem. News* 112, 203-5, 295-7(1915); 113, 85-7(1916); cf. *C. A.* 7, 628, 2775, 3515; 8, 3667; 9, 1494, 2922.—The physical characteristics, including soil preferences, of the following plants are given, together with their org. chem. constituents as detd. by the usual methods of plant analysis and analysis of ash: Canary grass (*Phalaris arundinacea*), purple loosestrife (*Lythrum salicaria*), heather (*Calluna vulgaris*), ragwort (*Senecio jacobaea*), hairmoss (*Polytrichum commune*), early purple orchis (*Orchis mascula*), marsh marigold (*Calitha palustris*), hedge mustard (*Allaria officinalis*), tufted vetch (*Vicia cracca*), bogbean (*Menyanthes trifoliata*). A few of the more general conclusions are that the production of mucilage is in no way related to the production of CaC_2O_4 . The absorption of humic matter from the soil appears to serve as a basis for the formation of mucilages and hemicelluloses, but not of starch and certain sugars. Plants bearing flowers containing carotin require, even when the top soil is peaty, a substratum of sand or gravel where the relation of N to C is rather high. Many of the habits of plants are deduced from their chem. compn., anatomical structure, and physiologic activity. L. W. RIGGS.

The presence of hematoid compounds of iron in plants. I. G. GOLLA. Roy. Bot. Gardens, Turin. *Atti accad. Lincei* 24, I, 1239-43(1915).—Earlier work on the nature of compds. of Fe in plants is reviewed. G. (*Ann. botanica, Rome* 5, 441(1907)) had previously detd. the existence of organic Fe compds. in many aquatic plants and has now extended these expts. and has extd. from many kinds of plants org. compds. of Fe which are all similar to each other and which by their distribution in tissues and in the most widely various organisms permit of an hypothesis on the physiologic function and on the nature of the organic compds. of Fe. At first G. used plant tissue free from chlorophyll but later used the method for the green plants also. Pine or poplar sawdust was macerated with 0.3% NaOH. The ext. was sepd. and acidified with AcOH; it gave a brown amorphous ppt. the ash of which was rich in Fe. By extg. with Na_2CO_3 instead of NaOH less impurities come out with the ppt. This concn. of the alk. soln. for extn. varies with the material to be extd. In this ppt. is the part containing Fe which is sol. in dil. alks. and which is pptd. from these solns. on acidifying. Heating the ppt. with aq. alkalies does not easily sep. the Fe. The ppt. is insol. in neutral org. solvents; it is sol. with partial alteration in AcOH and is more changed in aq. AcOH; its incomplete soly. in $\text{C}_6\text{H}_5\text{N}$ shows that it is not homogeneous; heated 3-5 hrs. with KOH-EtOH it is decompd. and evolves NH_3 , probably derived from protein inclusions. After heating in a Ag crucible with KOH at 200-40° for 5-7 hrs. in an air bath under a layer of petroleum the mass was extd. with cold abs. EtOH and was almost completely dissolved. That part not dissolved contained only a little Fe. A little dry glycerol was added to the EtOH soln. and then 1.5 vol. Et_2O ; this gave a dark brown layer consisting mostly of glycerol poor in K. This was sepd. and acidified with glacial AcOH; treatment with 2 vols. Et_2O and centrifuging sepd. most of the Et_2O and AcOH; a 2nd treatment with Et_2O removed all AcOH. The brown amorphous compd. thus obtained is nearly insol. in neutral solvents; it is sol. in $\text{C}_6\text{H}_5\text{N}$. This compd. gives a *picrate* as a brown amorphous mass which melts easily and burns with deflagration and a luminous flame, and from which excess picric acid can be removed by washing with petroleum satd. with EtOH. The picrate may be decomposed by hydrolyzing with H_2O or better by the action of $\text{C}_6\text{H}_5\text{N}$, which dissolves the picrate but not picric acid. On adding Et_2O the Fe compd. is pptd. and can be purified by repeating this process. Heated with Zn it evolves alk. vapors, probably NH_3 , and gives the pine chip reaction for pyrrole. Aq. alkalies rapidly sep. the Fe; acids (AcOH) do this a little more quickly; in 4-5 days a purple violet ppt. seps. which on treatment with dil. HCl gives the $\text{K}_4\text{Fe}(\text{CN})_6$ test for Fe.

The portion insol. in EtOH after the KOH fusion was mostly dissolved with glacial AcOH and treated with picric acid gave a *picrate* similar to that above. That part insol. in glacial AcOH also gave a similar *picrate*. Whether these are different compds. present in the plant or represent stages of the action of KOH was not detd. Although there are some objections, G. considers these compds. to be similar fundamentally to the hematin of the blood. Further expts. are under way. One quintal of poplar sawdust gave 170 g. of the crude Fe compd.; 1 quintal of dry vegetation gave 430 g.

NORMAL.

The soy bean and condensed milk in infant feeding. JOHN RUHRÄH. *Am. J. Med. Sci.* 150, 502-12(1915).—From his experience in using the soy bean, condensed milk and some cereal (for additional carbohydrate) in proper proportions, R. feels that this method of feeding can be used without any danger TULA LAKE HARKEY.

A résumé of infant feeding. CHARLES H. SRYBERT. Philadelphia. *Hahnemannian Monthly* 51, 210-7(1916).—A review. JOSEPH S. HEPBURN.

Studies on the digestion of cooked meat by dogs. E. ZUNZ. *Biochem. J.* 9, 17-35(1915).—Analyses of the stomach contents of dogs after the ingestion of meat are given. Z. suggests the use of the character of the protein decomposition products as an index to protein metabolism. B. H.

Influence of fat and carbohydrate on the excretion of endogenous purines in the urine of dog and man. NOBUYOSHI UMEDA. Glasgow. *Biochem. J.* 9, 421-38(1915).—A study of the possibility of the synthesis of uric acid in the mammalian body. In man, on a diet rich in carbohydrate, some evidence of the synthetic formation of uric acid was obtained. In the dog the same result was obtained by the addition of allantoin to the diet. The protein-sparing action of carbohydrate as compared with fat was again clearly demonstrated. The output of endogenous uric acid in human urine was increased after the ingestion of glycerol or NaHCO₃. Several expts. showed that a decrease in the output of purine bases resulted in an increase in the excretion of uric acid. In fat-rich diets (carbohydrate-poor) the output of uric acid was markedly diminished. B. HOROWITZ.

Influence of carbohydrate and fat on protein metabolism with special reference to the output of sulfur. KWANJI TSUJI. Glasgow. *Biochem. J.* 9, 439-48(1915).—It is known that ingestion of carbohydrate brings about a reduction in the output of N in the urine, and that fat tends to increase this output when carbohydrate is present in small amt. T.'s object was to study the S output under similar conditions. The method employed was that of superimposition, *i. e.*, on a particular day there was added to a standard diet the special foodstuff to be tested, the N and S content of which was known. In some cases the diet was rich in fat and correspondingly poor in carbohydrate. The subject of the expt. was a healthy bitch weighing approx. 13 kg. She was catheterized each morning and the urine added to that collected in the receiver of the cage. The methods of analysis were: Total N, Kjeldahl; total S, Benedict; inorganic and alkyl sulfates, Folin. The feces were not examd. The standard diet was continued until the output of total N and total S became fairly regular. Then an amt. of the protein to be tested, which contained approx. 6 g. of N, was added to the standard diet at the usual feeding time. The standard diet was then continued until the output of total N and total S was again regular. The extra amts. of N and S excreted were detd. by the subtraction of the av. amt. of N and S excreted on the 3 days immediately preceding the superimposition from the av. after the addition. In 3 expts. the retention of super-

imposed N was greater on a carbohydrate than on a fat diet. In 2 expts. out of three the same was true for S. The amt. of extra N and S excreted varies with the protein used. The greater part of the extra S excreted is in the form of inorganic sulfates. The partition of S on the carbohydrate and fat diets is very similar; it is for the most part excreted in the form of inorganic sulfates and neutral S in almost equal amt. There is no evidence that the protein retained after superimposition is poor in S.

B. HOROWITZ.

The use of phlorhizinized dogs to determine the utilizable carbohydrate in foods. The food value of commercial glucose. W. D. SANBURN AND R. T. WOODYATT. Rush Medical College. *J. Biol. Chem.* 24, 23-9(1916).—In 5 expts. completely phlorhizinized dogs, which were also rendered glycogen-free by injection of epinephrine, received 1-2 g. per kg. of body wt. of commercial glucose or corn sirup by mouth and a control dose of a corresponding wt. of C. P. *D*-glucose. The control doses of *D*-glucose did not reappear quant. in the urine and apparently some sugar was retained or burned in the body. The best yields were obtained by maintaining free diuresis through administration of salines supplemented by suitable amts. of alkali. The commercial glucose yielded 93.48 % as much extra sugar as the same wt. of C. P. *D*-glucose so that at least that % of the solid matter in the sample of com. glucose studied was "capable of passing through whatever physiological processes of digestion, absorption and assimilation are necessary for its ultimate existence in the body as *D*-glucose." There was no evidence of any deleterious effects attributable to the ingestion of commercial glucose. "The expts. are considered of interest as showing the possibility of using the diabetic organism for resolving a heterogeneous mixt. of carbohydrates and allied compds. into the form of a single easily measured sugar, and as casting light on the compn. and utilizability of that mixt. of glucose, dextrins, and other substances known as commercial glucose."

The value of amino acid compounds with formaldehyde for the nitrogen economy of animals. Azzo Azzi. Univ. Naples. *Atti accad. Lincei* 24, I, 1125-9(1915); see C. A. 9, 1943.

E. J. WITZEMANN.

ABNORMAL.

Prolonged fasting in diabetes. FREDERICK M. ALLEN. *Am. J. Med. Sci.* 150, 480-5(1915).—The main features wherein the proposed treatment differs from previously established methods are: (1) A fast of one or two days longer than is necessary to clear up glucosuria; (2) a subsequent diet such as to keep glucosuria and acidosis permanently absent, with as many interspersed fast days as are necessary; (3) keeping the most severe diabetics intentionally and permanently at a sufficiently low level of wt. and metabolism to prevent return of symptoms and downward progress, and (4) opposition to the doctrine that fat feeding does not appreciably influence diabetic glucosuria and that calories lost in the urine should be replaced by additional calories in the diet, preferably in the form of fat. The author feels that whatever the ultimate outcome, present knowledge seems to justify the conclusions: (1) That this treatment removes glucosuria and acidosis more quickly and surely than do former methods of treatment, and (2) that patients do better when glucosuria and acidosis are removed than when these conditions are allowed to continue.

TULA LAKE HARKEY.

Output of creatine in glucosuria. KWANJI TSUJI. Glasgow. *Biochem. J.* 9, 449-55(1915).—The purpose of the author was to obtain further evidence in support of the view that the reported appearance of creatine in the urine of animals in which the carbohydrate metabolism has been interfered with is due to the metabolic disturbance, and is not merely an error in observation due to the presence of acetoacetic acid. Cathcart and Orr (*J. Physiol.* 48, Proc. xxi (1914)) have shown that phlorhizin can give rise to a creatinuria without an accompanying acidosis. Since phlorhizin

glucosuria is associated with a renal disturbance, T. selected cases of glucosuria (1) following the injection of adrenaline, and (2) post-anesthetic. Injection of adrenaline (a soln. 1 : 1000—Parke, Davis & Co.) increases the output of total N. This rise is not due to any increase in one particular constituent but to a general increase of all the constituents estd. (ammonia, Folin method; creatinine and creatine, Folin methods, after the urine being treated as recommended by Graham and Poulton; urea, urease method; sugar, Benedict method; acetone and acetoacetic acid, Messinger-Huppert method). On the day of injection there was glucosuria, and associated with it the appearance of creatine. That this is a real creatine excretion and not merely apparent, due to the presence of acetoacetic acid, is shown when the total acetone excreted is considered. The results with carbohydrate-rich and carbohydrate-poor diets were identical. When ether anesthesia was employed, the urine for the day on which the animal was anesthetized was divided into 2 parts for examn. because of the transitory nature of the changes produced: (a) the urine which was excreted and obtained from the bladder by catheter before the anesthetic was given, and (b) the urine collected for the rest of the 24-hr. period after the anesthetic. Using a carbohydrate-rich diet, no rise in the output of total N on the day of narcosis was obtained, but there was a very slight rise in the output on the following day. There was a slight rise in the excretion of urea, a definite fall in the output of NH_3 , a slight fall in creatinine, the appearance of a trace of creatine, a slight glucosuria, and a slight increase in the output of total acetone. The presence of creatine was shown also by the diacetyl test. Using a carbohydrate-poor diet, there was a definite rise in the excretion of NH_3 on the day of anesthesia. The output of creatine was unaltered on the day of expt., but there was a marked fall on the day following. No sugar was detected in the urine. The output of creatine was a mere trace. There was a small but appreciable rise in the excretion of total acetone.

B. HOROWITZ.

The effect of phlorhizin on the formation of glycogen in the liver. ALBERT A. EPSTEIN AND GEORGE BAHR. Mt. Sinai Hosp., N. Y. *J. Biol. Chem.* 24, 17-21 (1916).—In phlorhizinized cats from which the kidneys have been removed, the presence of phlorhizin in the body actually stimulates the accumulation of glycogen in the liver. "With the kidneys intact, the glucosuric action of phlorhizin is so much more powerful than this liver action that the glycogen accumulations in the liver are rapidly diminished. Upon removal of the kidneys, however, the glucosuric action is eliminated and the effect upon the liver becomes manifest in a rapid building up of glycogen, even in a state of extreme starvation." As the % of blood sugar never rose above the normal figure, it is not probable that the accumulation of excess of sugar after nephrectomy was due to a disturbance in carbohydrate metabolism produced by the phlorhizin.

A. P. LOTHROP.

Experimental contribution to the etiology of pellagra. KARL RUHL. *Dermatol. Woch.* 60, 113-26, 151-8, 176-80 (1915); *Tropical Diseases Bull.* 7, 65 (1916).—This is principally a study of the effect of red light. R. found that no photodynamic reaction takes place in guinea pigs and that these animals are not suitable for these expts. Red light, even with mixed diet, delayed the development of young animals, but had no effect on adults. Red light, with exclusive maize diet, resulted in the death of 80%. R. believes the red light is not harmful, but rather the exclusion of the chemically active violet and ultraviolet rays. His final conclusion is that Funk's vitamine theory is not proved and that Raubitschek is mistaken in considering pellagra to be a photodynamic problem.

C. J. WEST.

Diabetes and pellagra. EUGENIO BRAVETTA. *Riv. pellagrol. ital.* 15, 43-7 (1916). *Tropical Di* 59 (1916).—Good food represents the best remedy

to assuage, to cure and perhaps to cause the complete disappearance of pellagra.

C. J. WEST.

Histological lesions after exclusive maize diet, starvation and experimental scurvy. PIETRO RONDONI AND MARIO MONTAGNANI. *Sperimentale* 69, 659-96(1915); *Tropical Diseases Bull.* 7, 63(1916).—In guinea pigs fed only on maize, the organs chiefly affected are the spleen, thyroid gland and suprarenals and after them, the central nervous system. Less effect was found in the liver, digestive canal, kidneys, bone marrow, myocardium and lungs. The authors maintain that sclerosis of the thyroid is enough to distinguish "maidism" from the results of starvation. They believe that their pathological studies help to admit pellagra into the group of diseases due to the deficiency of nutrition.

C. J. WEST.

Maize diet from the point of view of the etiology of pellagra. PIETRO RONDONI. *Sperimentale* 69, 723-97(1915); *Tropical Diseases Bull.* 7, 63(1916).—Maize is an unsatisfactory and insufficient food for man and for various animals. From expts. on guinea pigs it is thought likely that the anti-maize vitamine is different from the anti-scurvy vitamine. The view is still held that the food value of maize depends upon the kind and the district in which it is grown. Adrenaline administered to sick and emaciated guinea pigs, by mouth, under the skin or intraperitoneally caused them to live several days longer than the control animals, which were apparently suffering with "hypo-adrenalism." In spite of the obvious difficulties, R. believes that the effects of a prolonged maize diet, which should be almost exclusive, should be studied on monkeys or on man. He recommends as prophylaxis the substitution of other cereals, potatoes, fresh vegetables, meat and milk for some of the maize of the diet. Addition of protein, peptone, amino acids, glucose, tabloids of thyroid glands, allantoin, etc., to the maize diet had no conclusive effects.

C. J. WEST.

Acidosis and some of the factors which influence it. R. M. LANG. Glasgow. *Biochem. J.* 9, 456-78(1915).—In healthy individuals, on a constant diet, the total acetone excreted is practically constant in amt. The quantity found is influenced by the diet, being greater with a high protein intake than with a low one. The acetone output in the early days of starvation is governed by the nature of the preceding diet. Both carbohydrate and protein when administered to the fasting organism cause a rapid diminution in the amt. of "acetone bodies" found in the urine. Fat causes an immediate drop in the total acetone output during the first 4 hrs. and this is succeeded by a definite rise. Glycerol reduces acidosis; alc. has no effect.

B. HOROWITZ

Influence of salts on amylolysis in bread (EFFRONT) 12.

F. PHYSIOLOGY.

ANDREW HUNTER.

Human milk. G. D. ELSDON. *Analyst* 41, 74(1916).—Two samples from the same sources on successive days contained: fat, 4.0 and 3.5; lactose, by diff., 7.5 and 7.4; protein, 1.5 and 1.4; ash, 0.2 and 0.2%. The mixed fat taken on several successive days showed the following consts.: n_{40} 1.4568; Zeiss butyrefractometer, at 40°, 46.3; R.-M. value, 5 g., 2.0; Polenske value, 2.2; Kirschner value, 1.9. Complete analyses of 67 samples gave the following av. max. and min. figures, resp.: Total solids, 11.7, 14.6, 9.6; solids-not-fat, 8.59, 9.1, 8.0; fat, 3.11, 5.9, 1.1; proteins, 1.19, 1.8, 0.7; ash, 0.21, 0.3, 0.2; lactose, by diff., 7.18, 7.6, 6.6%. Av., max., and min. figures of 79 partial analyses are also given: Total solids, 11.78, 14.3, 9.4; solids-not-fat, 8.50, 9.4, 7.9; fat, 3.28, 5.7, 0.7%.

W. O. E.

The innervation of dentin. J. HOWARD MUMMERY. *Dental Cosmos* 58, 258-69 (1916).—A histo-chemical demonstration of the presence of nerve fibers in the dentinal tubules.

JOSEPH S. HEPBURN.

Effect of ingestion of urea, sodium lactate and sodium hydrogen carbonate on the reaction of the blood and the composition of the alveolar air in man. GORO MOMOSE. *Physiol. Lab., Cambridge. Biochem. J.* 9, 485-91 (1915).—M.'s object was to test the question whether certain substances taken by the mouth make the blood in the body more alk. Katl (*C. A.* 10, 348) has shown that addition of certain alk. substances to the blood (NaOH , Na_2CO_3 , NaHCO_3 , Na_2HPO_4), accelerates the oxidation and retards the reduction of the blood. Alkali, then, would increase the percentage satn. of O in blood exposed to a given O pressure, just as acid reduces the percentage satn. (Barcroft, Camis, Mathison, Roberts and Ryffel, *Trans. Roy. Soc. London (B)* 206, 49 (1914)). M. used this measurement as a test for the changed reaction. The method of exposing blood to a standard gas mixt. is that described by Kato (*C. A.* 10, 1361), in which 0.1-0.2 cc. is put into the bulb of a small pipet, and gas is passed over it from a gas holder, the pipet being rotated in a water-bath at 37-38° for about 10 min. This gives complete equil. between the blood and the gas. 0.1 cc. of blood is then analyzed for its percentage satn. by the use of the differential gas analysis app. (Barcroft, *The Respiratory Function of the Blood*, p. 300 (1914)). Urea, Na lactate and NaHCO_3 , taken by the mouth, cause the blood to become more alk., i. e., cause the percentage satn. in the blood to rise when exposed to the standard mixt. On the other hand, these substances, in the doses taken, produce little change in the alveolar CO_2 .

B. HOROWITZ.

Thrombin and calcium chloride in relation to coagulation. J. O. W. BARRATT. *Lister Inst., London. Biochem. J.* 9, 511-43 (1915).—B. studied the quant. relation between the time of coagulation of fibrinogen and the amt. of thrombokinase taking part in the process of coagulation, in presence of CaCl_2 .

B. HOROWITZ.

Mechanism adapting the oxygen capacity of the blood to the requirements of the tissues. H. C. DALLWIG, A. C. KOLLS AND A. S. LOEVENHART. *Univ. Wisconsin. Am. J. Physiol.* 39, 77-108 (1915).—Expts. on small animals kept in respiration chambers under reduced atm. pressure or in an atm. of low O concn. but normal pressure prove that a decrease in the partial pressure of the O of the respired air caused an increase in the erythrocytes and hemoglobin per unit vol. of blood and that the increase occurs even at atm. pressure under conditions which eliminate all of the physical effects of decreased barometric pressure and high mountain climates. The erythrocytes are increased as a result of the stimulation of the bone marrow in response to decreased O tension and the increase is abs. not relative. O pressure must be reduced at least to 14% of an atm. to produce these effects. Stimulation results even when O pressure falls to 6% of an atm.

J. F. LYMAN.

Stimulation of the hypophysis in dogs. R. W. KEETON AND F. C. BECHT. *Northwestern Univ. Am. J. Physiol.* 39, 109-22 (1915).—Expts. conducted under conditions which precluded hyperglucemia as a result of the anesthesia employed showed that elec. stimulation of the hypophysis in dogs caused a rise in reducing substances of the blood. Stimulation anteriorly or posteriorly to the hypophysis caused no such rise provided precautions were taken to prevent an escape of current to the gland. The fact that dogs whose splanchnic nerves had been cut from 30 to 137 days previous to hypophyseal stimulation showed no rise in blood sugar is opposed to the hormone theory of hypophyseal action whereby cellular glycogenolysis is directly increased. With active diuresis glucosuria appeared when the reducing substances of the blood were equiv. to 0.190 to 0.21% dextrose. Once established, sugar in the urine increased out of proportion to the reducing power of the blood.

J. F. LYMAN.

Effect of aqueous extracts of organs upon the contractions of unstriated muscle fibers. G. G. FAWCETT, J. M. RAHE, G. S. HACKETT AND JOHN ROGERS. Cornell Univ. Med. Coll. *Am. J. Physiol.* 39, 154-61(1915).—The filtrate from H₂O exts. of pituitary, pineal, thyroid, parathyroid, thymus and adrenal glands after removal of nucleoproteins, globulins and coagulable proteins contains most or all of the internal secretions of these organs as shown by expts. on unstriated muscle of cat uterus or intestine. The action on the muscle in different parts of the intestine varies. Epinephrine paralyzes unstriated muscle stimulated by exts. of the above glands; therefore the region affected by these organ exts. must be some portion of the termination of the sympathetic nerves.

J. F. LYMAN.

Action of pituitary extracts upon the isolated intestinal loop. V. N. SHAMOFF. Harvard. *Am. J. Physiol.* 39, 268-78(1916).—The posterior lobe of the pituitary gland contains some substance which has an action on the isolated intestinal loop resembling the action of epinephrine. This active substance may not be identical with the compds. in the posterior lobe which cause hemodynamic and diuretic responses.

J. F. LYMAN.

Secretory discharge of the pituitary body produced by stimulation of the superior cervical sympathetic ganglion. V. N. SHAMOFF. Harvard. *Am. J. Physiol.* 39, 279-90(1916).—Stimulation of the superior cervical sympathetic ganglion after section of both vago-sympathetic trunks in the middle of the neck and of the spinal cord at the fourth thoracic segment caused diuresis and glucosuria in the cat, a result which can best be interpreted as due to the discharge of hypophyseal secretion by the stimulation of the hypophysis and the subsequent action of the hormones contained therein.

J. F. LYMAN.

Effects upon gastric secretion of organ extracts. JOHN ROGERS, J. M. RAHE, G. G. FAWCETT AND G. S. HACKETT. Cornell Univ. Med. School. *Am. J. Physiol.* 39, 345-53(1916).—The non-coagulable portion of a H₂O ext. of the thyroid contains a substance which, when injected subcutaneously, is an active stimulant of both gastric secretion and gastric motility. Gastric secretion is stimulated only by the non-coagulable portions of the H₂O exts. of parathyroids, thymus, spleen and liver. Both the coagulable and non-coagulable portions of pancreatic exts. increase the flow of gastric juice. The pituitary and adrenal glands yield a non-coagulable H₂O-sol. portion which inhibits gastric secretion. All the stimulant fractions appear to act upon some peripheral gastric mechanism in which the nervous system is an essential part.

J. F. LYMAN.

Effects of testicular transplants upon vasomotor irritability. H. WHEELON AND J. L. SHIPLEY. St. Louis School Med. *Am. J. Physiol.* 39, 394-400(1916).—Castration tends to lower the irritability of the sympathetic nervous system as shown by the comparative response to nicotine. After castration the vasomotor response to nicotine averaged 50% lower than reactions to the same drug before removal of the glands. After transplants of testicular tissue had been made in the neck muscles, the response averaged only 23% below normal. It is concluded that a direct relationship does exist between the internal secretion of the testis and the sympathetic nervous system.

J. F. LYMAN.

The physiology of cholesterol metabolism. KARL LOWENTHAL. Berlin. *Beitr. Path. Anat.* 61, 564-9(1916).—In hypercholesterolemic conditions which follow the entrance of cholesterol into the blood stream from the body fat depots, the amt. of cholesterol is decreased in the testicles; nevertheless the testicle does not belong to the reticulo-endothelial system, which is the center of intermediary cholesterol metabolism. After complete castration, the amt. of cholesterol in the blood increases. Whether

this hypercholesterolemia is lasting and on the loss of what particular part of the testicle it depends, remains questionable. Unilateral castration is apparently without effect.

JULIAN H. LEWIS.

G. PATHOLOGY.

H. GIDEON WELLS.

Immune reactions against tumor growth in animals with spontaneous tumors. M. S. FLEISHER AND L. LOEB. St. Louis. *J. Med. Res.* 34, 1-19(1916).—Mice with spontaneous tumors are not so good a soil for the growth of transplantable tumors as normal controls. This may be due to age or to the effects of tumor growth on nutrition. Certain mechanisms which inhibit in normal mice the growth of a transplantable tumor have the same effect in mice with spontaneous tumors. One of these mechanisms may consist in the production of certain immune substances. Following the extirpation of a transplanted tumor the presence of immune substances or immune mechanisms, produced by the growth of the transplanted tumor, can be demonstrated by further attempts at transplantation. Spontaneous tumors on the other hand do not produce, in any considerable quantity, immune substances comparable to those produced by the ordinary transplanted tumors; neither do spontaneous tumors neutralize immune substances produced by the growth of transplantable tumors. GEO. T. CALDWELL.

Superficial fatty streaks of arteries: an experimental study. J. W. MCMEANS AND O. KLORZ. Pittsburgh. *J. Med. Res.* 34, 41-63(1916).—A hypercholesterolemia was produced in rabbits by feeding varying amts. of cholesterol in olive oil and cholesterol Na oleate mixts. At autopsy, 115 to 160 days after the beginning of the treatment, there were observed in the aortas of the animals fatty streaks closely resembling the fatty streaks so frequently seen in the human aorta in individuals dying of acute infections, severe blood diseases and uremia. The deposit in these areas contained much demonstrable cholesterol. GEO. T. CALDWELL.

The colloidal gold precipitating substance in the cerebrospinal fluid in paresis. P. G. WESTON. Warren, Pa. *J. Med. Res.* 34, 107-12(1916).—The gold-pptg. substance is destroyed by boiling for 5 min. It is dialyzable through thimbles impermeable to protein. Its exact nature has not been detd. but it is not peptone. Colloidal gold was not found to be a delicate or reliable test for minimal quantities of peptone. The salts, Cu-reducing substance and Wassermann-reacting substance from cases of paresis do not ppt. gold from colloidal suspension when the fluid containing them is used in the same or larger quantities than are used in Lange's test. The Wassermann-reacting substance is not dialyzable. GEO. T. CALDWELL.

A comparison of the natural hemolytic activity of fresh human sera against guinea-pig and sheep erythrocytes. H. W. WADE. New Orleans. *J. Med. Res.* 34, 113-9(1916).—Natural anti-guinea-pig hemolytic activity occurs in human serum in considerable regularity and uniformity of concn. This hemolytic combination is much superior to the natural anti-sheep hemolysin as serological reagent since the latter appears less constantly and with greater variability of concn. Only 4.2% of human sera is non-hemolytic to guinea-pig corpuscles while 16% is inactive with sheep corpuscles. GEO. T. CALDWELL.

The urea content of the cerebrospinal fluid. R. G. CANTI. London. *Lancet* 1916, I, 344-8.—The normal physiological urea content of the cerebrospinal fluid, as measured by the hypobromite method, is below 0.05%. Of patients dying of uremia, the majority are found to have a greatly increased quantity of urea in the cerebrospinal fluid, usually about 10 times and occasionally more than 20 times the normal amt. Each case in which a greatly increased quantity of urea has been found in the cerebrospinal fluid in a brief period. GEO. T. CALDWELL.

Studies of nephritis. HENRY A. CHRISTIAN, CHANNING PROTHINGHAM, JR., JAMES P. O'HARE AND ALLEN C. WOODS. *Am. J. Med. Sci.* 150, 655-80(1915).—(A) In testing renal meals in relation to renal function, two methods were used—those of v. Monakow and of Hedinger and Schlayer—and similar results obtained. Fixation in excretion of N seems to develop at a later period generally than is true of water and salt. (B) Quantitative studies of non-protein nitrogenous substances of the body. Urea N averaged 63.4% of the total non-protein N of the blood, and its increase was usually proportionate to the increase of the total non-protein N. Ammonia N increased slightly but not proportionately; the same held for uric-acid and amino-acid N. Creatinine showed roughly a proportionate increase. There is no advantage in quant. detg. the N of the spinal fluid over detg. it in the blood. There is no relation between the amount of non-protein N in the blood and changes in the retina. (C) Diuresis in relation to diuretics. Observations justify skepticism as to the efficacy of diuretic drugs in cases of nephritis without cardiac decompensation. (D) No constant relations were found between anatomical lesions and renal function in so far as excretion of phenolsulfonethalein, albumin in the urine, casts, presence or absence of edema, blood-pressure detns., etc., are concerned.

TULA LAKE HARKEY.

Observation upon the elimination of acetone and diacetic acid in two hundred and fourteen surgical cases. M. R. BRADNER AND S. P. REIMANN. *Am. J. Med. Sci.* 150, 727-33(1915).—Acetone, occasionally accompanied by diacetic acid, was eliminated in the urine of 182 out of 214 surgical patients. The temperament of the individual and the length of time of pre-operative treatment appeared to have a slight positive effect upon the acetone eliminated. Both are eliminated in larger quantities and oftener in women than in men. Surgery alone increased the acid, but the severity of the operation and the amt. of obvious shock present had but little bearing upon the amt. of eliminated acid and the time of elimination.

TULA LAKE HARKEY.

An acidimetric study of the saliva and its relation to diet and caries. JOHN H. MARSHALL. Univ. California. *Dental Items of Interest* 38, 116-27(1916).—No relationship exists between the acidity and alkalinity of normal resting saliva and the susceptibility to caries. In approx. 200 cases examd. not one was found in which a markedly carious condition was associated with a notably acid saliva. The diet is without influence on the compn. of the saliva. In immune conditions the relationship of the neutralizing power of the normal resting saliva to that of the activated saliva varies within relatively wide limits. In the carious condition, this relationship varies within relatively narrow limits; consequently growth of bacteria, including lactic acid organisms, is favored, and lactic acid is formed in sufficient strength to act on the Ca salts of the teeth.

JOSEPH S. HEPBURN.

Studies in experimental diabetes after pancreatectomy. ALBERT A. EPSTEIN AND GEORGE BAEHR. Mt. Sinai Hosp., N. Y. *J. Biol. Chem.* 24, 1-16(1916).—After pancreatectomy there is a tendency for the animals to drink H₂O in large amts. and there is a consequent increase in blood vol. sometimes reaching 150%. Such changes in blood vol. must be taken into consideration in order to obtain an accurate estimation of the variations in the sugar, non-coagulable N and other blood constituents. After pancreatectomy in the cat the hyperglucemia rises progressively in the terminal stages due to renal insufficiency, as the marked hyperglucemia was accompanied by albuminuria and a diminished glucosuria and acetoneuria. A similar excessive rise in blood sugar is observed in human diabetes and is an indication of impending coma. A rapidly progressing hyperglucemia is produced in depancreatized cats by removal of the kidneys, the accumulation being due to the gradual mobilization of the reserve carbohydrate from the liver and muscle.

A. P. LOTROP.

Liver circulation in relation to glucemia. HUGH MCGUIGAN AND E. L. ROSS. Northwestern Univ. Med. School. *Am. J. Physiol.* 39, 480-9(1916).—Portal ligation caused a rise in blood sugar of 62% of the original; hepatic ligation caused no greater increase than ether alone. Ligation of both blood vessels did not increase blood sugar. Hyperarterialization of the liver increased the sugar of the blood 35% of the original while hypervenuosity did not cause such increase. "The utmost conceivable uncomplicated change in the circulation of the liver can play but a minor role in the production of glucosuria or diabetes."

J. F. LYMAN.

Indicanuria and ocular affections. VARNI. *Ann. oftalmol.* 1914, 514; *Zentr. Biochem. Biophys.* 18, 390(1915).—Indicanuria does not possess the significance of an autointoxication and neither is it a pathognomonic indication of a general affection. Indicanuria is rather to be regarded as a fortuitous condition which has no connection with ocular affection.

H. S. PAINE.

Remarks on the work of Römer and Gebb: "Investigation of the biological behavior of blood serum toward lens albumin in cataract, V, VII." E. v. HIPPEL. Göttingen. *Arch. Augenheilk.* 78, 364(1915); *Zentr. Biochem. Biophys.* 18, 398(1915).—Polemical with reference to comments (*Arch. Augenheilk.* 78, No. 1/2) by R. and G. on a previous paper by v. H. entitled "Abderhalden method in cataract" (*C. A.* 8, 3464).

H. S. PAINE.

Structure and formation of biliary calculi. HUGO RIBBERT. Vienna. *Arch. Path.* 220, 20(1915); *Zentr. Biochem. Biophys.* 18, 178-9(1915).—The faceted, pigmented biliary calculi contain little or no Ca; they originate from soft, irregular masses which are composed of bile ppts. and possess at first no particular structure, being generally rounded in shape. In these masses there occurs a cryst. sepn. of cholesterol as tablets, spear-shaped figures and larger, radiating masses which appear as white granules; the bile pigment seps. from the original mixt. at the same time and appears as a yellowish brown to dark brown mass which is mixed with crystals in a varying manner and is impregnated with H₂O. Around the soft nucleus which is being transformed by the attachment of sepd. crystals there are deposited harder masses whereby sepn. of cholesterol and bile pigment occurs in a more regular manner and radial deposition of crystals ensues. Formation of strata occurs at the same time, while pure cholesterol layers alternate with pigment layers. In many gall stones there is a center or nucleus composed of minute fragments of crumbled stones or several united masses of irregular shape. The shape of the stones is quite independent of their chem. compn.; the significant fact is that sepn. (which further depends on the varying degree of fullness of the gall bladder) occurs at intervals. A pure cholesterol stone originates in a non-inflamed gall bladder through a simple process of crystn. (from bile rich in cholesterol) around any central nucleus (which is no longer detectable in the final stone). In case several irregular masses are formed these become mutually flattened out in pyramidal form and become enlarged by peripheral deposition of cholesterol, especially at the angles and edges (where more bile pigment is also deposited.)

H. S. PAINE.

Substances which excite growth of connective tissue. ROST AND R. WERNER. Heidelberg. *Deut. Z. Chir.* 133, 344-54, 355-67(1915); *Zentr. Biochem. Biophys.* 18, 376(1915).—Transplantation expts. with rabbits showed that only a slight connective tissue-like reaction was occasioned by recently transplanted tissue. The reactive proliferation of connective tissue was more pronounced when the tissue had previously been brought to incipient decompn. by means of autolysis. Röntgen rays especially influence tissue cells by causing the production therein of substances with pronounced excitant action on connective tissue. Peru balsam, scarlet red, naphthalan, ichthyol, etc., have no especial influence on connective tissue proliferation. R. and W. detected in mineral oils a series of substances which have considerable effect in stimulating

connective tissue. This action probably depends on the content of unsatd. hydrocarbons in these mineral oils.

H. S. PAINE.

Appearance of antitoxins in the anterior chamber of the eye. POLEV. *Klin. Monatsbl. Augenheilk.* 52, 819(1914); *Zentr. Biochem. Biophys.* 18, 401(1915).—Expts. on horses which had been immunized with diphtheria toxin showed that antitoxin appeared in the anterior chamber of actively immunized animals in an amt. of 1:250-900 as compared with its content in the serum; the amt. in the aq. humor was not the same in the various animals and was not proportional to the antitoxin titer of the serum.

H. S. PAINE.

Disturbance of liver function during pregnancy. B. BAUCH. Cologne. *Monatschr. Geburtshelk.* 42, 258(1915); *Zentr. Biochem. Biophys.* 18, 391(1915).—Out of 22 healthy pregnant women 14 excreted little or no sugar in the urine after administration of 40 g. galactose, while 8 excreted amts. of sugar which were comparable to the amts. eliminated by healthy non-pregnant women under similar circumstances. The sugar content of the blood showed normal values and experienced at most a quite insignificant increase due to the action of galactose. Hyperglucemia was not observed in healthy pregnant women; it was, however, detected in a case with symptoms of slight pregnancy toxicosis (this increased distinctly after galactose administration). These results indicate that impairment of liver function does not occur in healthy pregnant women.

H. S. PAINE.

Investigations of the organs and experimental studies of non-dropsical chlorine retention. J. LEVA. Berlin. *Z. klin. Med.* 82, 1-7(1915); *Zentr. Biochem. Biophys.* 18, 385(1915).—L. presents tables which show that the human organs may in pathol. cases (renal, cardiac and vascular affections) store twice the normal amt. of Cl (even thrice the normal amt. in the skin) without any essential increase in H₂O content; non-dropsical Cl retention may therefore take place in the human organism within these limits. Expts. with rabbits which had been rendered nephritic with U gave analogous results.

H. S. PAINE.

Excretion of various urinary constituents in liver affections. W. VON MORACZEWSKI AND E. HERZFELD. Zürich. *Z. klin. Med.* 82, 61-77(1915); *Zentr. Biochem. Biophys.* 18, 391(1915).—Total N, uric acid + purine bases, NH₃, volatile acids, Me₂CO, amino acids, indican and indole were quant. detd. in the urine (also N and indole in the feces) of patients suffering from liver affections (catarrhal jaundice, liver cirrhosis, etc.), healthy individuals in a condition of fast, diabetics, and patients suffering from renal affections and diseased conditions of the blood. No difference was detected between catarrhal jaundice and liver atrophy. Fasting, as well as fever, was found to modify liver functions. Excretion of all the substances which were quant. detd. was increased in affections of the liver, while only certain ones of these values were found to increase during a fast, diseased conditions of the blood, etc.

H. S. PAINE.

An enzyme theory of cancer. LEVERETT D. BRISTOL. Univ. of North Dakota. *Med. Record* 89, 180-90(1916).—Cancer is the result of localized hyperoxidation in epithelial cells and is induced by concd., accelerated and uninhibited action of intracellular oxidizing enzymes "as a result of [the presence of] various injurious agents."

A. H. RAHE.

H. PHARMACOLOGY.

ALFRED N. RICHARDS.

Chronic lead-poisoning in guinea pigs; with especial reference to nephritis, cirrhosis and polyserositis. W. OPHÜLS. *Am. J. Med. Sci.* 150, 518-41(1915).—Chronic lead-poisoning in guinea pigs produces severe degenerative changes in the epithelium of the kidneys and of the liver, leading to necrosis. These destructive lesions are partly

compensated for by constant regeneration. In the kidneys these lesions may eventually cause collapse of certain groups of tubules associated with moderate proliferation of the connective tissue and some chronic inflammatory changes. The glomeruli in these foci usually show a fibrous thickening of the capsule. In exceptional instances the defects produced in this way are large enough to cause a somewhat granular gross appearance of the organs. In the liver, large areas of collapse occur more frequently, so much so that marked irregularity of the surface resembling that observed in human cirrhosis is quite common. The connective tissue proliferation associated with this process is extremely limited, and therefore should be designated, not as a cirrhosis, but as a chronic focal atrophy. It produces general increased permeability of the blood vessels leading to the production of effusions, usually of a hemorrhagic character, into the serous cavities. These are most commonly observed in the pericardium, but the pleurae and the peritoneum are often also involved in the process. False membranes are apt to form on the surface of the serous membranes and their organization leads to the development of the picture of chronic polyserositis with fibrous thickening and sometimes adhesions.

TULA LAKE HARKBY.

The germicidal efficiency of dental cements. PAUL PORTSCHKE. Phila. *Dental Cosmos* 58, 325-31(1916).—"A critical review" of Smirnow's paper on the same subject (*C. A.* 10, 210).

JOSEPH S. HEPBURN.

The inflammatory tissues of the gingival margin and periodontal membrane: treatment by ionic medication. ERNEST STURRIDGE. London. *Dental Cosmos* 58, 403-6(1916).—The chemical principles underlying ionic medication are discussed. An expt. is reported, demonstrating the penetration of ions into tissue for a considerable distance with very low current strength. This medication is an excellent mode of antiseptis for deep tissues, *e. g.*, in pyorrhea alveolaris.

JOSEPH S. HEPBURN.

Are there any laws which govern the behavior of dental amalgams? N. K. GARTHART. *Dental Register* 70, 62-6(1916).—All amalgams made solely from base metals are sol. in the oral secretions, *e. g.*, Cu-Cd amalgam. The insolubility increases directly as the Ag content. Hardness or edge strength increases directly with the Ag content until the "period of saturation" or amalgam of max. hardness is reached; still higher Ag content causes too rapid setting. Retention of color depends on hardness; oxidation and action of sulfides are resisted by a hard and highly polished amalgam surface. The period required for setting, which begins as soon as the excess of Hg is removed from the plastic mixture of alloy and Hg, depends on the ratio of the metals in the alloy and on the quantity of Hg added; the amalgam should contain a max. of Ag and minima of Sn and Hg. Shrinkage increases as the time of setting grows greater.

JOSEPH S. HEPBURN.

Chemical treatment for pyorrhea alveolaris-necrotic tissue. J. S. BRIDGES. Chicago. *Dental Review* 30, 248-52(1916).—A description of the physiological action of certain compounds ($MgSO_4$, ZnO , $BiONO_3$, $PhOH$, aconite, eugenol, lanolin) when they are applied locally in the treatment of pyorrhea.

JOSEPH S. HEPBURN.

A review of some drugs old and new. S. F. M. HIRSCH. Cleveland, O. *Dental Summary* 36, 138-44(1916).—A discussion of the pharmacological action of $EtCl$, cocaine-HCl, novocaine, adrenaline, eugenol, $PhOH$, cresol, $HCHO$, $CuSO_4$, $ZnCl_2$, $CaCl_2$, $AgNO_3$ and emetine.

JOSEPH S. HEPBURN.

The place of the silicates in dentistry. CHARLES C. VOELKER. Brooklyn, N. Y. *Dental Summary* 36, 177-97(1916).—A statement of the compn. and the chemical and physical properties of the silicate cements.

JOSEPH S. HEPBURN.

Stovaine, a spinal anesthetic. JAMES G. SPACKMAN. Wilmington, Del. *Hahnemannian Monthly* 51, 130-2(1916).—Stovaine blocks the nerve roots. It is more stable

than cocaine, a more powerful anesthetic and but $\frac{1}{2}$ as toxic. Cardiac failure, due to stovaine, is counteracted by infusion of adrenaline in normal saline, or by intravenous injection of caffeine citrate, strychnine sulfate and adrenaline. JOSEPH S. HEPBURN.

A natrium muriaticum case. RUDOLPH F. RABE. New York City. *J. Am. Inst. Homoeopathy* 8, 1013-5(1916).—A report on the physiological action of NaCl given in homeopathic doses. JOSEPH S. HEPBURN.

Cimicifuga. ELLA M. TUTTLE. New Berlin, N. Y. *J. Am. Inst. Homoeopathy* 8, 1040-2(1916).—A discussion of the physiological action of tincture of cimicifuga (*Actaea racemosa*). JOSEPH S. HEPBURN.

Fixation of salvarsan and neosalvarsan by the blood after intravenous injection. WILLIAM J. YOUNG. Austral. Inst. of Tropical Med., Townsville. *Biochem. J.* 9, 479-84(1915).—Nierenstein (*Annals Trop. Med. Par.* 2, 249, 323(1908)) has shown that when serum is shaken with atoxyl (sodium *p*-aminophenylarsenate) and the proteins pptd. with tannic acid, the ppt. contains As which cannot be removed by washing. He further observed that when derivs. of atoxyl were used instead of atoxyl itself, As was present in the ppt. only in those cases in which the deriv. contained a free amino or imino group. The same occurs when atoxyl and its derivs. are injected into animals (Breinl and Nierenstein, *Deut. med. Wochschr.* 34, 1181(1908); *Z. Immunitäts-fors.* 1, 620(1909); *Annals Trop. Med. Par.* 3, 395(1909); *C. A.* 4, 468). Y. performed expts. to ascertain whether similar combinations could be obtained with salvarsan and neosalvarsan. Since these compds. are less stable than atoxyl, only expts. with living animals were made. Goats were injected intravenously with salvarsan or neosalvarsan and blood was drawn after various intervals of time. The blood was allowed to clot and the serum poured off and filtered. The serum was then dialyzed in parchment bags against running water (or saline) until all dialyzable As was eliminated. The serum was now filtered, decomposed with HNO_3 and H_2SO_4 , and evapd. The residue was tested for As by the modification of Gutzeit's method as recommended by Sanger and Black (*C. A.* 2, 975, 2352). In every case As was found. The ppt. caused by the addition of tannic acid to the serum gave a positive As test. Inorg. As is not bound to the serum in a similar manner. The combined As is found in blood long after free salvarsan and neosalvarsan have been removed. This combined As is confined to the plasma and the red blood cells. None is retained by the fibrin.

B. HOROWITZ.

Sodium hypochlorite in the treatment of septic wounds. FREDERICK J. A. DALTON. *Brit. Med. J.* 1916, I, 126-8—Dakin's antiseptic soln. (cf. *C. A.* 9, 2943) was applied to 15 cases of septic wounds. The decreased number of redressings required, and the safety with which the hypochlorite may be applied by untrained persons, make it of particular value in war surgery. A. H. RAHE.

Radium. C. E. FIELD. New York. *Med. Record* 89, 135-9(1916).—Twenty cases are cited in which Ra was used for the reduction of blood pressure. A. H. R.

Experimental study of the effect of emetinized blood on the typhoid bacillus. MARCUS BEEKMAN. *Med. Record* 89, 284(1916).—Tests performed on a human subject showed that subcutaneous injection of emetine-HCl does not impart bactericidal properties to the blood. A. H. RAHE.

Autolysin. S. P. BEEBE. *N. Y. Med. J.* 103, 360-4(1916).—A description of the compn. and method of prepn. of "autolysin," an herbal mixt. A. H. RAHE.

Experimental study of the influence of quinine in hemoglobinuric fever. RAYMOND BIJON. *Bull. Soc. Path. Exot.* 8, 597-604(1915); *Tropical Diseases Bull.* 7, 31(1916).—There is a diminution of the resistance of the red blood corpuscles and a lysin exists in the blood. The lysin comes into action owing to a failure of the

body to produce the necessary anti-lysin. Quinine has an action on the lysin either by satg. it or perhaps indirectly destroying malarial parasites. Quinine cannot have any effect on the progress of hemoglobinuric fever but only on its etiology, by accidentally pptg. the onset in an individual who is already in a state of malarial intoxication and will almost certainly have an attack later even without the administration of any quinine.

C. J. WEST.

Some refractories used in dentistry. GUY S. MILLBERRY. *Dental Register* 70, 75-85(1916); see C. A. 10, 616.

From the visible to the gamma-ray spectrum. SIDNEY RUSS. Middlesex Hospital. *Brit. Med. J.* 1916, I, 124-6.—One of the objects of this article is to put forward a plea for a more exact specification of the different types of radiation which are used experimentally and therapeutically.

A. H. RAHE.

Emetic action of oil of strophanthus (HATCHER) 17.

I. ZOÖLOGY.

R. A. GORTNER.

The production of light by animals. ULRIC DAHLGREN. Princeton Univ. *J. Franklin Inst.* 180, 513-37, 711-27(1915); 181, 109-25, 243-61, 377-400, 525-56(1916).—These papers give a comprehensive description of the production of light by bacteria, protozoa, fungi, sponges and coelenterates, echinoderms and lower mollusks, and cephalopods, respectively. The physiology and histology of the light organs are described, and attention is paid to the biochemistry of luciferin and its oxidation with the production of light.

JOSEPH S. HEPBURN.

Oxygen and carbon dioxide content of the blood during hibernation in the woodchuck (*Marmota monax*). A. T. RASMUSSEN. Cornell. *Am. J. Physiol.* 39, 20-30 (1915).—During hibernation of the woodchuck there is a slight increase in arterial CO_2 and a marked increase in venous CO_2 (33% in venous blood about the middle of torpidity). Venous blood has a decidedly lower and arterial blood a slightly lower O content during hibernation.

J. F. LYMAN.

Resistance of fresh-water fish to changes of osmotic and chemical conditions. W. E. GARREY. Washington Univ. *Am. J. Physiol.* 39, 313-29(1916).—Fresh-water fish (*Notropis blennioides*) live in distd. H_2O for weeks provided the skin is uninjured. In sea water death is sudden but sea water dild. to the concn. of the blood is a perfectly balanced soln. Solns. of cane sugar are directly toxic, least so when isotonic with the blood. The toxicity of cane sugar solns. is reduced by alkalies and by salts. Individual solns. of the chlorides of Na, K, Ca, and Mg are toxic in the order $\text{K} > \text{Mg} > \text{Ca} > \text{Na}$. Toxicity of solns. of CaCl_2 , MgCl_2 and KCl is decreased by NaCl ; of NaCl , KCl and MgCl_2 by CaCl_2 ; of CaCl_2 and KCl by MgCl_2 . MgCl_2 did not show an antagonistic action against NaCl , nor KCl against CaCl_2 , MgCl_2 and NaCl . In combinations of 2 or more of the other salts the antagonistic decrease of toxicity by K and by Mg is apparent. An alk. tap water is not noticeably injurious to these fish.

J. F. LYMAN.

Reaction and resistance of fishes in their natural environment to acidity, alkalinity and neutrality. M. M. WELLS. *Biol. Bull.* 29, 221-57(1915).—Fresh-water fishes select a slight acidity in a gradient, when the other choices are neutrality and alkalinity. They choose slight alkalinity in preference to neutrality. The CO_2 optimum for the species of fishes varies from very close to neutrality for the blue gill to 6 cc. per l. water for the goldfish. This is for the Nov. to Jan. conditions. At other seasons the optimum probably varies. The optimum acid concn. for the blue gill is about 0.00005 N H_2SO_4 . The distribution of the reaction in N. Y. shows a correlation with the chem. reaction

of the water. There are fewer animals at neutrality than in slightly alk. or slightly acid water. The neutrality of distd. water is a factor to be considered with reference to its toxicity. Cf. C. A. 10, 939. L. W. RIGGS.

Effects of certain organic and inorganic substances upon light production by luminous bacteria. E. N. HARVEY. *Biol. Bull.* 29, 308-11(1915).—The effects on luminous bacteria of diln. of sea-water with water, *M* sugar soln., HCl, valeric acid. NaOH, CH_3NH_2 , salts of sea-water in different combinations, and of methyl, ethyl, propyl, butyl, amyl, and capryl alcs. were studied and the results are shown in 4 tables. Changing the compn. of sea-water in any way generally diminishes the amt. of light given off by the luminous bacteria. Cf. C. A. 10, 74. L. W. RIGGS.

Nitrogenous constituents of *Paralithodes camtschatica* and *Polypus punctatus*. E. TAKAHASHI. *J. Coll. Agric., Tohoku Imp. Univ.* 6, 289-302(1915).—The work of various authors on the compn. of crab meat and of mollusks is reviewed. By T.'s method with *P. camtschatica*, 2200 g. fresh crab meat were hashed and repeatedly extd. with H_2O at 60° until the combined exts. measured 6.5 liters. Total N in 100 g. of the fresh meat is 2.71 g.; H_2O -sol. N 1.26, which was made up of albumin N 0.308, ammonia N 0.021, N pptd. by phosphotungstic acid 0.342, remaining N 0.589. The phosphotungstic fraction calcd. to 100 parts of fresh meat gave N pptd. by AgNO_3 0.013, pptd. by AgNO_3 and Ba(OH)_2 0.109, remaining N 0.218. In 100 parts of H_2O -sol. N there was found albumin N 24.44, ammonia N 1.67, N pptd. by phosphotungstic acid 27.14, remaining N 46.75. In 100 parts of N pptd. by phosphotungstic acid there was found N pptd. by AgNO_3 3.81, N pptd. by AgNO_3 and Ba(OH)_2 31.91, remaining N 64.28. Detailed directions are given for the isolation and detn. of the bases with the following results: One kg. of crab meat contained histidine (hydrochloride) 0.041, arginine nitrate 0.91, betaine 2.0, tyrosine 0.125, leucine 0.46, and purine bases were present. Two kg. of the clear flesh of *Polypus punctatus* (ink snail) were extd. with H_2O at 50 - 60° , the combined exts. measuring 4.5 liters. Calculated to fresh meat 100 parts gave sol. matter 7.942, sol. N 0.787, sol. albumin 0.142, basic N 0.315. The bases were isolated as cryst. products with the following results: One kg. fresh meat contained taurine 3.73, carnosine (picrate) 2.39, betaine 3.28, histidine (methyl ester hydrochloride) 0.54 g. (cf. following abstr.). L. W. RIGGS.

Occurrence of betaine in some sea animals. E. TAKAHASHI. *J. Coll. Agric., Tohoku Imp. Univ.* 6, 303-9(1915).—Detailed directions are given for the extn. and purification of betaine from the meat of the lobster and from 2 species of mussels, with the following results, the figures for the crab and ink snail (cf. preceding abstr.) being added for comparison: One kg. of fresh meat of *Pandalus* sp. 2.0, *Macra sachalinensis* 5.0, *Pecten yessoensis* 0.6, *Paralithodes camtschatica* 2.0, and *Polypus punctatus* 3.28 g. (Cf. Suzuki, *et al.*, C. A. 4, 223, 1051.) L. W. RIGGS.

Electromotive phenomena and membrane permeability. J. LOEB. *New York Science* 42, 643-6(1915); cf. C. A. 10, 344.—A review and criticism are given of the ground taken by Bayliss in the latter's address (cf. *Science* 42, 509(1915)), and from the work of L. and Beutner shows that the fact that an active part of a tissue becomes negative to a part at rest is explained by assuming "that in the active part of the tissue substances are formed which temporarily alter the potential at the inner surface in such a sense as to make the outside on that spot appear more negative. There is no necessity for assuming any increase in the permeability of the skin." L. W. RIGGS.

Cell penetration by acids. W. J. CROZIER. *Bermuda Biol. Sta. Science* 42, 735-6(1915); cf. C. A. 8, 2197.—The water-sol. blue pigment in the cells of a nudibranch, *Chromodoris zebra*, is a sufficiently delicate indicator for use in this study. The pigment is insol. in anhydrous acetone, Et_2O , CHCl_3 , xylene, and oils. It turns pink

with acids and green with alkalis. Comparatively uniform pieces of the lateral mantle edge were treated by the method of Harvey (cf. *C. A.* 8, 3080), the acids being 0.01 *N* concn. The time of penetration in min. at 27° was for different acids as follows: isovaleric 1.9, salicylic 3.5, formic 4.5, HCl 7.6, HNO₃ 8.4, H₂SO₄ 8.5, lactic 8.6, oxalic 8.8, tartaric 13.5, citric 16.0, butyric 19.0 and acetic 75.0. These results are in general agreement with those of Harvey on the testis of *Stichopus ananus*. By testing the penetration of these acids over a range of concns. (0.1 to 0.001 *N*) and arranging results to show penetration-dilution curves a very different picture is obtained. The acids fall into 2 groups the first consisting of oxalic and the 3 mineral acids, and the second group of the others. Further details are promised.

L. W. RIGGS.

12. FOODS.

W. D. BIGELOW, F. F. FITZGERALD.

The analysis of maple products. VII. The electrical conductivity test for the purity of maple sirup. J. F. SNELL. *J. Ind. Eng. Chem.* 8, 331-3(1916); cf. *C. A.* 7, 4021; 8, 380, 1839; 10, 940, 1059.—Errata in Paper I (cf. *C. A.* 7, 4021) are corrected. The test has been modified to suit the new Van Zoeren electrode which S. now uses. 20 cc. of the sirup are measured into a 100 cc. beaker from a 25 cc. graduate, allowing thorough draining. Two successive portions of distd. water each equal in volume to the sirup taken are added from the same graduate. The mixt. is put into a dip electrode, thoroughly stirred, brought to exactly 25°, and the measurement made. The const. of the cell is divided by the observed number of ohms, and the results multiplied by 100,000. Cond. values as low as 96 and as high as 230 have been met with in genuine sirups. The limits of percentage variation of the cond. value in genuine sirups are much narrower than those of any of the older analytical values but not as narrow as those of the volumetric lead no. Values above 200 have not been met with except in kettle-boiled and pan-boiled sirups.

E. A. TSCHUDY.

The occurrence of sucrose in relatively large amounts in a new seedling grape. W. B. ALWOOD AND J. R. EOFF, JR. *J. Ind. Eng. Chem.* 8, 334-5(1916).—A seedling grape, apparently of the *labrusca* group was examd. frequently for 60 days, and during this period the sucrose content varied between 5.23 and 10.36%. This is higher than previously reported for any grape. The analyses of 17 samples collected at intervals from Aug. 23 to Oct. 22 are tabulated.

H. S. BAILEY.

The occurrence of sucrose in grapes of American origin. H. C. GORE. *J. Ind. Eng. Chem.* 8, 333-4(1916).—An examn. of 66 varieties of grapes grown in Vineland, N. J., during 4 successive seasons shows that 43 contained no sucrose. In 10 sucrose was found occasionally, and in 13 varieties it was frequently present. The tabulated data show as much as 5% of sucrose in one variety (Lady), in 1913, and none in the same grape in 1914.

H. S. BAILEY.

A comparison of the methods for the determination of casein in milk. C. B. HERSHEY. *J. Ind. Eng. Chem.* 8, 335-6(1916).—The Van Slyke volumetric, the Hart centrifugal, and the Official Nitrogen methods for the detn. of casein in milk were compared on 143 samples of Calif. milk. The av. found by the Official method was 2.47, by Hart's 2.52 and by Van Slyke's 3.07; max. 3.31, 3.4, 3.70 and min. 1.71, 1.81 and 1.05%, resp. 70% of the detns. by the Hart method gave results higher, 6.0% equal to, and the remainder less than the Official method. With the Van Slyke method 77% of the results were above, 1.0% the same, and the rest below the A. O. A. C. method, but the amt. of variation was greater with the V. S. than with the Hart method. For all ordinary work the Hart method, when an elec. centrifuge is used, is as accurate

as the Official method, and far superior to the V. S. method. It is very much quicker, and requires neither exact standard solns. nor final calcs. H. S. BALEY.

The importance of determining the specific gravity of milk serum as a means of detecting water adulteration. HERRAMHOF. *Molkerei Ztg. (Hildesheim)* 28, No. 7, 115-8 (1914).—After an investigation extending from June, 1912 to February, 1913, H. reached the following conclusions: (1) The sp. gr. of the serum of milk from the same cows remains practically const.; it varies less than the sp. gr. of the milks examined. (2) The sp. gr. of the serum is lowered in proportion to the amt. of water added. (3) The serum obtained by spontaneous coagulation is preferable to that obtained by any other method. (4) The sp. gr. of the serum remains const. after 3 days and, in the case of a perfectly clear filtrate, even after 4 days. (5) Cloudy milk serum can be made clear by filtering through bone-black without affecting the sp. gr. G. A. MENGES.

Comparative experiments on pasteurized and biorized milk. R. BURRI AND A. C. THAYSEN. Bern-Liebfeld. *Z. Gärungsphysiol.* 5, 167-86(1915).—"Biorized" milk, prep'd. by spraying raw milk into a heated chamber and cooling, was compared with pasteurized milk. It was found that milk biorized at 75° was practically equiv. to milk pasteurized 1/2 hr. at 65°, as regards peroxidase reaction, catalase reaction, time of coagulation by rennet, Schardinger reaction, and bacterial count. A. W. DOX.

"Herramhof's fat-tester," an apparatus for determining fat in cheese, dry milk, cream, etc., in practice. HERRAMHOF. *Molkerei Ztg. (Hildesheim)* 28 No. 36, 677-9 (1914); *Exp. Sta. Record* 33, 314.—The app. employed consists of 2 parts, a flask which receives the cheese to be tested and the butyrometer proper. The outer wall of the mouth of the flask and the inner wall of the butyrometer are so ground as to form a sealed joint. The butyrometer is graduated to 0.5%. In the test 2.5 g. cheese is weighed into the flask and 6 cc. H₂SO₄ (d. 1.5) is added. The flask and contents are heated on an asbestos plate until the cheese is completely dissolved, and 16.5 cc. H₂SO₄ (d. 1.5) and 1 cc. AmOH are added. The butyrometer attachment is then placed on the flask and the app. kept for about 30 sec. on the hot plate. After going through the other details of the procedure, the butyrometer attachment with its contents is stoppered with a rubber, whirled in a centrifuge for 3 min. and placed in a water-bath at 67°. The height of the fat column is then read. The total solids of the cheese may be estd. by drying the cheese in the flask previous to adding the H₂SO₄. The methods of detg. fat in dry milk, cream, and milk are also described. G. A. M.

The present status of milk-drying technic. EMIL FREUND. *Wiener Landw. Ztg.* 65, 663-4, 669-71(1915).—F. describes the different methods used in the prep'n. of milk powder and points out their advantages and disadvantages. Several illustrations are given. C. F. MILLER.

"Poli" Oil, a new adulterant of ghee, Indian clarified butter-fat. J. H. BARNES AND ARJAN SINGH. *Analyst* 41, 72-3(1916).—Poli is a name applied to a weed of Northwest India, *Carthamus oxyacantha*, one of the safflowers, belonging to the natural order Compositae. Its seed is edible, and yields a yellow oil, sometimes used as an illuminant, and also as an adulterant of ghee or Indian clarified butter. For the latter purpose its color and taste render it very suitable. The consts. of the fresh oil are: d_{15.5} 0.9272, I value 167.4, sapon. value 174.2, acetyl value 60.5, acid value 5.9, R.-M. value 0.61, [α] nil, n_{20}^D 1.4818, n_{40}^D 1.4755. P. B. DUNBAR.

Influence of salts on amylolysis in bread. J. EFFRONT. *Mon. sci.* [5] 6, 5-12(1916).—The role of the saliva is to dissolve the starchy substances in the course of the first hour of gastric digestion. The HCl of the gastric juice stops salivary digestion of pure starch, but the starchy matter of bread offers greater resistance to the acid, due to the P₂O₅. Whole-wheat bread, having more phosphate than white bread, is more easily

digested. The salts of di- and tribasic acids in bread neutralize the HCl. The monophosphate formed exerts a direct action on the amylolytic enzyme, rendering it more resistant to the free acids.

C. S. M.

The fruit of the horse-chestnut, and its use as human and animal food. H. SERGER. raunschweig. *Chem. Ztg.* 40, 221-2(1916).—Expts. on feeding the nuts to calves, pigs and sheep have shown the best results with calves, as the bitter taste was less objectionable to these. The bitter may be removed by boiling the crushed nuts a short time with several changes of H₂O, after which they may be prepd. for feeding other domestic animals. For human food, extn. with H₂O did not completely remove the bitter taste. A 1% soln. of K₂CO₃ removed the bitter taste but left a disagreeable sweetish taste which can be removed by extg. with 50% alc., giving a flour suitable for baking. Treating the nuts with alc. before extg. with H₂O did not remove all the bitter taste. Cf. Auld, C. A. 7, 1769; Laves, *Chem. Ztg.* 26, 954(1902).

J. H. M.

Native pasture grasses of the United States. DAVID GRIFFITHS, GEO. L. BIDDLE and CHAS. E. GOODRICH. Bur. Plant Ind., U. S. Dept. Agr., *Bull.* 201, 52 pp. (1915).—Data are given regarding over 140 species, analyses being given in most cases.

E. J. C.

Fruit by-products. W. V. CRUESS. *Calif. Sta. Rept.* 1915, 31.—C. refers to the production of clear, palatable jellies from citrus fruits. The jelly stock is cleared by settling and filtration or by clarification with Spanish clay. Small amts. of SO₂ checked darkening and development of a musty taste. Household methods of manufacture have since appeared in Univ. Calif. Sta., *Circ.* 146.

W. V. C.

Enzymes of apples and their relation to the ripening process (THATCHER) 11D. The poisonous forms of the lima bean (DUNLOP) 11D. Hydrolysis of some of the common vegetable oils (RUDD) 27. Action of ozone on microorganisms and artificial substrates, as shown by ozone treatment in the cold storage of meat (HEISE) 11C. Dried potato pulp (PAROW) 16.

Drying apple or other fruit juices. J. C. FLEMING. U. S., 1,174,404, Mar. 7. Freshly expressed juice is mixed with powdered malt and the mixt. is evapd. at a low temp. and then more completely dried under a protecting cover of animal charcoal to obtain a "fruit flour," which may be added to wheat flour and other materials used in baking.

Tomato extract. G. FERRICHS. U. S., 1,174,248, Mar. 7. A tomato ext. is prepared by fermenting pulped tomatoes with yeast and sepg. and inspissating the fermented juice. The destruction of the sugar present gives a product which is similar to meat ext.

Coffee extract. K. B. VON VIETINGHOFF. U. S., 1,175,490, Mar. 14. A readily sol. dry coffee ext. is prepd. by exhausting roasted powdered coffee berries with a fat-solvent and then with H₂O, evapg. the solvent from each ext. and mixing the 2 exts. after separately roasting the aq. ext.

Solid coffee extract. K. B. VON VIETINGHOFF. U. S., 1,175,091, Mar. 14. A completely sol. coffee ext. is made by lixiviating roasted coffee beans with H₂O, evapg. the ext. to dryness and roasting the dry residue at a temp. of about 225° for 10 min. or longer while permitting free escape of the vapors given off. The aromatic constituents may first be removed from the beans by C₆H₆ or CCl₄ and subsequently added to the aq. ext.

"Vegetable milk" from soy beans. W. J. M. S., 1,175,467, Mar. 14. Soy bean meal is stirred with hot H₂O to a thick slurry and the slurry is freed from

soy oil by centrifuging, and sesame oil or other edible oil, fatty acid, sugar, salts, citric acid and lactic culture in imitation of cow milk or cream are added and the product is pasteurized.

Pasteurizing milk. G. SINCLAIR. U. S., 1,175,876, Mar. 14. Pasteurizing milk without destroying lactic acid bacilli is effected by gradually heating the milk to about 65° to acclimatize the lactic acid bacilli to this temp., sterile air is then passed through the milk to remove noxious gases, the temp. is flashed to about 82° and after cooling to 15° the milk is maintained at this temp. for a sufficient time to permit development of the lactic acid bacilli.

Sterilizing milk. O. LOBECK. U. S., 1,174,592, Mar. 7. Milk is atomized in a closed chamber surrounded by a heating jacket and allowed to flow over a heated inclined bottom of the chamber.

Sterilization of food products in sealed metallic containers. A. WEISSENTHALER. Fr., 477,920, Mar. 8, 1915. Oxygen is removed from the interior, and the cover is then forced into place while atm. pressure prevails.

Preserving fish. G. A. SMITH. Brit., 23,194, Nov. 27, 1914. In preserving fish by immersion in cooled, concd. and electrolyzed sea water, the fish is placed in boxes having louvered or slotted sides and adapted to fit into cases through which the brine is circulated. The brine is passed through a filter comprizing porous partitions, and C-charged cylinders which serve as electrodes. The cases are connected by pipes and cocks arranged so that one or more of the cases may be cut out of the circuit.

Infant food. M. FRANZIE. Fr., 477,949, Feb. 17, 1915. Steamed cereals are subjected to the action of ferments dissolving starch, or of fruits containing these ferments, whereupon the resulting mass is dried, broken up, and pulverized.

14. WATER, SEWAGE AND SANITATION.

EDWARD BARTOW.

Effect of flood water on ground water. A. LANG. *Intern. Z. Wasserversorg.* 1: 176-7(1915).—Water of springs and wells is shown to be affected by flood flow in near by rivers.

FRED W. TANNER.

The influence of algae of submerged sand filters on the chemical composition of water. L. GIZOLME. *Compt. rend.* 161, 313-6(1915).—Under the influence of sunlight chlorophyll decomposes CO₂, increasing the dissolved-oxygen content of the effluent as much as 3 parts per million. The alkalinity expressed in terms of CaO is decreased approx. 10 p. p. m. as a result of the pptn. of carbonates. At night, in the absence of light, respiration alone is active and the dissolved oxygen in the effluent is decreased below that of the raw water. The max. lowering of the alkalinity is produced several days after filter scraping. Bubbles of gas (55 to 60% O) are released from the water over the filters, more often in the evening during periods of max. alkalinity lowering. At such times the water is found to contain large numbers of diatoms and their presence is followed by the appearance of filamentous algae. These phenomena are more apparent in summer than in winter. Naturally the rate of filtration influences the raising of the O content and the alkalinity lowering.

W. F. LANGELIER

Purifying water for mine power plants. M. F. NEWMAN. *Mining Eng. World* 43: 851(1915).—N. gives an example of a large saving of expense by the installation of a water-softening system in connection with a mine power plant. The use of both nostrums and mechanical devices is not to be recommended.

E. GREENFIELD

Note on a new apparatus for use with the Winkler method for dissolved oxygen in water. H. L. SHOUB. Pub. Health Service, U. S. *Hyg. Lab. Bull.* 96, 83-5, 1914.

To obviate the necessity of calibrating and marking each new bottle, with subsequent calculations, a definite volume (200 cc.) of the soln. is withdrawn (with the least possible agitation and exposure to the air) and titrated. To save time and labor the app. shown in the fig. was devised. The 200 cc. pipet extends through a rubber stopper into a suction chamber made of 1-in. glass tubing. From the top of this chamber there project 2 tubes, one terminating in a glass cock open to the air, the other in the pressure regulator bottle shown below. The latter tube extends into the suction chamber and to a point within the end of the pipet which is exactly opposite its graduation mark. The pressure regulator bottle is connected directly to the suction system or may be connected to a Richards' aspirator. It holds a layer of Hg, above which is a layer of H₂O; a capillary tube enters this bottle through the center hole and projects slightly beneath the Hg surface. The submergence of this tube is so arranged that when the suction is applied at a const. and slow rate, H₂O will rise in the pipet and part way into the suction tube. When it has reached a point about opposite the upper end of the suction chamber air enters the regulator bottle through the submerged capillary and prevents further rise of the H₂O column. An approx. adjustment of this level is made by submerging the capillary in the Hg and it is finally adjusted by adding H₂O above the Hg until the desired result is obtained. Having regulated the app., it is operated as follows: the bottle of H₂O which has been prepd. for titration is placed in position

beneath the pipet and suction applied at such a rate that the pipet will just about fill in the time required for a titration. The stopcock leading to the air is closed. Titration of the previous sample is then proceeded with without further attention to the app. The liquid fills the pipet to its mark and then enters the upper tube up to a point about on a level with the upper rubber stopper, where it comes into equil. with the submerged capillary in the regulator bottle, air being admitted through the latter and the H₂O level remaining const. in the suction tube. The whole system is now in equil., and will remain so indefinitely. The bottle is next removed and a flask placed in a similar position. The stopcock is then opened to the air. The contents of the pipet are discharged rapidly into the flask, while the contents of the suction tube above its lower point are drawn over into the regulator bottle. The next sample is then put in place, the stopcock closed and the titration of the present sample proceeded with.

F. W. SMITHER.

Methods of sending specimens of water. JACK J. HINMAN, JR. *J. Am. W. W. Assoc.* 3, 224-8(1916).—The precautions which should be used in collecting samples of water for bacterial analysis are enumerated. The method here described is that in use by the Iowa State Board of Health. A gallon glass-stoppered bottle which has been sterilized according to the directions of the Am. Pub. Health Assoc. is used for collecting both the chem. and bacterial sample. For the ordinary analysis it is shipped to the lab. un-iced in a padded shipping case. Analyses for special purposes, such as filter control, are made on smaller amts. of water which are sent to the lab. packed in

ice. Field samples were taken in smaller amts. of 500 cc. which is sufficient for chem. and bacterial analyses according to the methods of Penniman and Enslow. For transporting this sample a special shipping case was devised which required 6 lbs. of ice. The box and bottle complete cost \$1.75 to \$2. Satisfactory results have been obtained with such app. F. W. T.

Sterilization of water by chlorine. J. J. H. NELSON. *Brit. Med. J.* 1915, I, 789-93.—The bottle A, shown in the diagram, is filled with water and the stopcock in the short tube closed. Two drachms of concd. HCl are placed in the small bottle B, 15 grains of KClO_3 added, and the stopper applied. The pressure in A is adjusted as required by opening the stopcock in the short tube. After the reaction is complete the contents of B are added to those of A, when the latter will contain a soln. of Cl_2 and ClO_2 of such strength that 1 oz. added to 5 gallons of water will give a diln. of Cl of 1:440,000. The app. is especially adapted to the use of troops in the field. Expts. are cited showing the effect of chlorination on natural and artificially infected waters. A. H. RAHR.

Efficiency of the liquid chlorine sterilization plant at Wakefield, Mass. E. C. SHERMAN. *N. E. W. W. Assoc.* 30, 135-42(1916); *Eng. Contrg.* 44, 410(1915); *Munic. Eng.* 49, 210(1915); *Munic. J.* 39, 811(1915).—From 9.5 to 1.24 parts per mil. of liquid Cl are used to sterilize water served to 13,000 population. The water contains large amts. of org. matter. The bacteria range from 30 to 1420 cc. in the raw water and only from 1 to 56 in the treated water. The plant cost \$600, with an operating cost of \$1.25 per mil. gal. LANGDON PEARSE

Substitute for potassium permanganate to liberate formaldehyde gas from a water solution. S. G. DIXON. Pa. Health Commission. *J. Am. Med. Assoc.* 64, 459(1915).—The following formula is recommended: $\text{Na}_2\text{Cr}_2\text{O}_7$, 10 oz. avoirdupois; satd. soln. HCHO gas, 1 pint; com. H_2SO_4 , 1.5 fl. oz.; glycerol, 1.5 oz. The glycerol is added to prevent freezing. If the soln. becomes cloudy it can be cleared by gently warming for a long period. L. W. RIGGS.

The water supply of Krakau from a hygienic standpoint. O. BUJWID. *Intern. Z. Wasserversorg.* 3, 35-7(1916).—A brief historical sketch of the development of the water supply is given. Water is taken from a series of 23 wells, the chem. and bacteriological characteristics of which are not significant. F. W. TANNER.

A water power reconnaissance in South-Central Alaska. C. E. ELLSWORTH AND R. W. DAVENPORT. With a section on Southeastern Alaska by J. C. HOYT. U. S. Geol. Survey, *Water Supply Paper* 372(1915). W. D. C.

The people's interest in water power resources. GEORGE O. SMITH. U. S. Geol. Survey, *Water Supply Paper* 400-A(1916). W. D. C.

A method of correcting river discharge for a changing stage. BENJAMIN E. JONES. U. S. Geol. Survey, *Water Supply Paper* 375-E(1915). W. D. C.

Conditions requiring the use of automatic gages in obtaining records of stream flow. C. H. PIERCE. U. S. Geol. Survey, *Water Supply Paper* 375-F(1915). W. D. C.

The Seattle water supply. JOHN WEINZIRL. *J. Ind. Eng. Chem.* 8, 369-71(1915).—Water is obtained from Cedar River by a pipe line 28.57 miles long. Special sanitary measures are employed to keep the water pure, and an emergency hypochlorite plant is maintained. Other protective measures might be adopted. R. BARTOW.

Ground water in Lasalle and McMullen counties, Texas. ALEXANDER DEUSSEN AND R. B. DOLB. U. S. Geol. Survey, *Water Supply Paper 375-G*(1916).—The supply of water is not very abundant and much of it contains too much mineral matter to be of use for domestic purposes or for irrigation. From 131 analyses (not very complete in most cases) the quality of the water in the different geologic formations is shown. For each water analyzed the scale-forming constituents, foaming constituents, and alkali coeff. are calcd. The waters are also classified as to their quality for boiler use, domestic use, irrigation, and as to probability of corrosion. W. D. C.

Water powers of the Cascade Range. III. Yakima River basin. G. L. PARKER AND F. B. STORREY. U. S. Geol. Survey, *Water Supply Paper 369*(1916). W. D. C.

Fat from sludge and the disposal of residue. JENCKEL. *Chem. Ztg.* 39, 492-3 (1915).—The process at Kassel is described; it consists in acidifying the wet sludge and treating at a temp. of 90 to 100°, filter-pressing, drying and extg. with benzene. Extd. sludge has proved to be of no fertilizer value and is only a waste product for the city. Extd. fat yields a good quality of stearin but it has not been shown that the income from it is sufficient to pay for its extn. and the disposal of the worthless sludge. One of the chief difficulties with the sludge is the removal of water. Cf. Bechhold (C. A. 9, 2410). W. D. HATFIELD.

Sewage disposal for isolated residences. C. G. GILLESPIE. Calif. State Board of Health, *Bull.* 11, 391-8(1916).—G. reviews the possible methods of waste disposal for isolated residences in rural districts. The methods discussed are leaching cesspool, septic tank, broad irrigation and subsurface irrigation. The advantages and disadvantages of these methods are treated together with brief statement of the cost. The entire system of wastes disposal for country homes should be constructed for about \$100 under conditions where labor would not have to be hired. \$40 or \$50 would cover the cost of materials. General plans and cross-sections accompany the paper.

FRED W. TANNER.

Recommends \$2,500,000 garbage plant for New York. JOHN T. FETHERSTON. *Eng. Record* 73, 349-50(1915).—The plant will be on Rikers Island and will have a capacity of 2800 tons. The plant will be of the Cobwell system of garbage treatment which is in operation at New Bedford, Mass. Financial agreement provides for the plant to revert to the city at end of 5 years on payment of 1.5 mil. dollars. New Bedford plant operation is detailed. FRANK BACHMANN.

Reaction and resistance of fishes in their natural environment to acidity, alkalinity and neutrality (WELLS) 11 I.

Water-softening apparatus. C. L. KENNICOTT. U. S., 1,176,368, Mar. 21. A float valve and connections control automatically the amt. of H₂O-softening chemicals in proportions adjusted to the amt. of H₂O to be purified which passes through the app.

Sterilizing liquids by means of ultraviolet rays. SOC. MÉRAN FRÈRES. Fr., 477,866, July 2, 1914. The liquid is conducted through a spiral trough under, and exposed to, the source of ultraviolet rays.

Preventing the formation of boiler scale. G. G. SCHLAEFFER. Fr., 477,879, Mar. 4, 1915. A pulverized carbonaceous substance is mixed with the feed H₂O. The substance is incorporated in a suitable saline soln.

Purifying sewage. G. W. and J. F. NAYLOR. Brit., 23,146, Nov. 27, 1914. Tanks for purifying sewage by aerating in the presence of sludge are divided by partitions having openings or pipe connections so that sewage and sludge pass successively through the compartments by gravity. Aerating devices consisting of porous tiles,

through which air is forced, may be placed at the back of the partitions so that injection of air assists the circulation.

15. SOILS AND FERTILIZERS.

R. O. E. DAVIS.

Preliminary studies on heated soils. JAMES JOHNSON. Univ. Wisconsin. *Science* 43, 434-5(1916).—Seed germination tests, in general, gave similar results, though different seeds varied much in their susceptibility to the injurious action. Plant growth is affected in much the same manner. Different soils give markedly different results upon heating to the same temps. The action appears to be dependent particularly upon the content of org. matter in the heated soil. The temp. to which the soil is heated is seemingly the most important factor in detg. the extent of the injurious or beneficial action; heating to approx. 250° had the greatest retarding effect on germination. Heating to 300° , or above, in all the soils used, again reduced the injurious action to seed germination and early plant growth, as well as the beneficial action to late plant growth. Heating soils to 250° produced greater amts. of material extractable with water than heating to higher or lower temps. The NH_3 content of the soil increased proportionally to the temp. up to about 250° , after which it rapidly fell to a minimum. This increase was accompanied by a decrease in nitrates, which were practically non-existent in the highly heated soils. The percentage of seed germination has been found to be closely correlated with the amt. of NH_3 present in the heated soils studied. The amt. of NH_3 required to injure germination, however, appears to vary with the type of soil. It appears that the absorptive power of the soil is a very important limiting factor in detg. the extent of the injurious action. That the toxic substance is of a volatile nature is evident by the fact that it is readily removed from the soil by aeration. If collected in water upon removal, its toxicity can be readily demonstrated. By collecting in a HCl soln. the resultant salt is NH_4Cl . Large amts. of CO_2 are produced when soils are heated. The evidence points towards the formation and injurious action of $(\text{NH}_4)_2\text{CO}_3$ particularly. It also appears that other compounds of NH_3 , more stable in character, are formed. The beneficial action of heated soils on plant growth, especially of those heated between 150° and 250° , is believed to be due largely to the direct assimilation of NH_3 or NH_3 compounds. The increased growth follows in practically all cases after a period of injurious action to plant growth. W. H. FRY.

The comparative effect of phosphates and sulfates on soil bacteria. E. B. FRY AND E. B. HART. Wisconsin Agr. Expt. Sta., *Research Bull.* 35, 35-6(1915).—The addition of mineral fertilizers to soils causes an increase in ammonification, CO_2 evolution and total number of bacteria. The addition of KH_2PO_4 to peptone soln. causes a great increase in the production of NH_3 . Merck's pptd. calcium phosphate (mixture of di- and tri-) causes a stimulation in the production of NH_3 in 5-day liquid cultures. Insol. $\text{Ca}_3(\text{PO}_4)_2$ in the form of bone ash did not aid NH_3 production by bacteria in peptone soln. CaSO_4 and K_2SO_4 increased ammonification slightly, the latter being more active, probably due to the K. The action of KH_2PO_4 as compared with that of K_2SO_4 shows that the K ion does not materially influence ammonification. KH_2PO_4 causes an enormous increase in the multiplication of bacteria. This is followed by a rise in NH_3 production which, however, is not in proportion to the number of bacteria, for the amt. of NH_3 produced by bacteria in these cultures is only $1/2$ that in cultures containing peptone soln. alone. In pure cultures of ammonifying bacteria in peptone soln. $\text{Ca}_3(\text{PO}_4)_2$ is ineffective in stimulating either ammonification or multiplication of bacteria. In Miami silt loam K_2HPO_4 stimulated ammonification and cell multiplication, as did also $\text{Ca}_3(\text{PO}_4)_2$. All phosphates increase the number of soil bacteria, this being most

marked in the case of K_2HPO_4 . $CaSO_4$ gives a slight increase in CO_2 evolution. Phosphates increased evolution of CO_2 when added to soil; with K_2HPO_4 this increase seemed proportional to the amt. of phosphate added. $MgSO_4$, K_2SO_4 and $(NH_4)_2SO_4$ increase CO_2 evolution from soil, the latter enormously. The results of this work as a whole suggest that possibly the increased crop-production of a soil resulting from the application of sol. phosphates is in part due to the promotion of bacterial activity. By the increased ammonification and consequent conversion of NH_3 into nitrates more N becomes available for rapid plant growth. The increase in CO_2 favors the soln. of the insol. minerals of the soil and thus helps to render available those mineral constituents needed for plant food. The sulfates, although as low in amt. in most soils as the phosphates, will not, in all probability, have the same general crop-producing power as the phosphates. This difference will undoubtedly rest on the differences in effect the 2 acid radicals have on the soil flora.

R. C. ROARK.

Two equipments for investigation of soil leachings. A pit equipment. C. A. MOORE, 3-5. A hillside equipment. W. H. MACINTIRE, 6-8. Tennessee Agr. Expt. Sta., *Bull.* 111(1915); 4 plates.—These equipments are pictured and their construction, cost and use fully described.

R. C. ROARK.

A new method for the determination of soil carbonates and new methods for the determination of soil acidity. E. TRUOG. *J. Ind. Eng. Chem.* 8, 341-5(1916); cf *C. A.* 10, 80.—A new form of app. for the detn. of soil carbonates is given. A test for the detection and detn. of soil acidity was developed. A distinction is made between active soil acidity and latent acidity. Active soil acidity is detd. by adding an excess of $Ba(OH)_2$ to the moist soil and passing in CO_2 to change the excess to carbonates. After evapn. a carbonate detn. gives the excess; from this the amt. required to neutralize the acidity is calcd. This is called active acidity since it combines instantly with bases brought in contact. The total acidity is detd. by boiling the soil with H_2O and $Ba(OH)_2$ and evapg. to dryness. The excess of $Ba(OH)_2$ is detd. as before. This total acidity minus the active gives the latent soil acidity. It is claimed that soil acidity is due to true acids and not selective ion adsorption by colloids.

J. J. SKINNER.

Comparison of methods for determining cohesion in soils. CARL MARQUIS. *Intern. Mitt. Bodenk.* 5, 381-516(1916).—M. compares the methods of measuring cohesion in soils with different moisture and lime contents. Expts. were made on the draft of plows under varying soil conditions. The moisture content caused greatest variation in cohesion values, and each soil shows its lowest cohesion at a different moisture content dependent on the character of the soil.

R. O. E. D.

Relation between water and soils. H. FISCHER. *Intern. Mitt. Bodenk.* 5, 518-76(1916).—Analyses of many soils and of soil waters were made where these types of soil were used with different kinds of treatment. The studies show that it is necessary in judging the value of a soil to analyze the soil and soil water and to carry out plot and pot tests and fertilizer expts.

R. O. E. D.

Moisture relations of some Texas soils. G. S. FRAPS. Texas Agr. Expt. Sta., *Bull.* 183, 5-36(1915).—This bulletin reports a study of the moisture content of 6 Texas soils under different conditions and treatment for 2 years. The av. amt. of water after continued rains is 58% of the water capacity measured in the lab., and the max. amt. is 69%. Cultivation and manure both increase the quantity of water held at the ends of the wet periods. The soils retained at the ends of the dry periods 44% of the water capacity measured in the lab. Cultivation increased the water content of the soils at the ends of the dry periods, as did also excrement.

R. C. ROARK.

The composition of the soils of the Texas Panhandle. G. S. FRAPS. Texas Agr. Expt. Sta., *Bull.* 173, 5-25(1915).—This bulletin deals with the chemical compn. of samples of soils from 26 counties in the Texas Panhandle.

R. C. ROARK.

Oxidation of organic compounds in the soil. G. S. FRAPS. Texas Agr. Expt. Sta., *Bull.* 181, 5-27(1915).—In a study of the oxidation of org. material by means of the loss on ignition it was found that the org. matter disappears rapidly during the first 3 weeks and after that the changes cannot well be followed. Corn chops, rice hulls, wheat shorts and wheat bran were oxidized 72 to 81% in 81 weeks, meat tankage and blood 47 to 68% and excrement and bat guano 15 to 22%. Cottonseed meal is oxidized about 10% in 1 day and nearly 30% in 4 days. The soils containing the least N appear to carry their C in a more easily oxidized condition. Soils when almost dry oxidized org. matter rapidly. Oxidation in a satd. soil may be very slow or moderate. CaCO_3 had little or no effect upon oxidation in the soil tested. R. C. ROARK.

Improving acid soils. A. W. BLAIR. New Jersey Agr. Expt. Sta., *Circ.* 54, 3-11(1916).—A discussion of why acid soils are undesirable, causes of acidity, methods of correcting, and results with magnesian and non-magnesian limestones. R. C. R.

Fertility and weeds. J. W. INCE. North Dakota Agr. Expt. Sta., *Bull.* 112, 235-47(1915).—Analyses of 30 common weeds are presented, showing content of dry matter, crude ash, N and P_2O_5 . Of 27 weed samples reported on the moisture-free basis, 24 contained more N and P_2O_5 than the av. for wheat, oats, barley or flax. The av. % of dry matter in wheat compared to that of wheat + weeds grown on equal areas was only 35.5%. The same relation for flax was 30.4%; for oats, 53.5%; and for barley, 79.5%. It is thus shown that weeds not only make a severe drain upon soil fertility, but successfully compete with crops in getting food from the soil. R. C. ROARK.

Report on commercial fertilizers. I. E. H. JENKINS AND JOHN P. STREET. *Annual Report of Conn. Agr. Exp. Station*, pp. 79(1915).—The present fertilizer situation is discussed and general suggestions are given. The various samples collected for analysis are given with analyses of same. B. E. B.

A proposed new method for citrate-insoluble phosphoric acid. CHAS H. HUNT. *J. Ind. Eng. Chem.* 8, 251-3(1916).—The fertilizer is digested as in the official method for total P_2O_5 and made up to a definite vol. An aliquot is taken and an excess of NH_3 is added, whereupon a white ppt. of $\text{Ca}_3(\text{PO}_4)_2$ is formed. It is then filtered and washed thoroughly with water. The ppt. is dissolved on the filter paper with HNO_3 and the P_2O_5 detd. in the filtrate according to the volumetric optional method. The ratio between the citrate-insol. P_2O_5 and that pptd. with NH_3 is about 1:1.50. This ratio varies in some cases, and the method does not seem applicable to superphosphates. The results seem to suggest a possibility of using a different factor for different types of fertilizers. The difference between the results obtained by the Official and proposed methods are no greater than the differences in the results obtained by different analysts working on the same sample when the Official method is used. W. H. FRY.

Determination of the phosphoric acid soluble in citric acid by the iron citrate method. N. ZACHARIADES AND J. CZAK. *Z. landw. Versw.* 18, 472-5(1915); through *Chem. Zentr.* 1915, II, 724.—The method of Popp was tested on Thomas meals. Addition of H_2O_2 for the oxidation of H_2S compds. is generally superfluous. The ppt. does not need to be filtered at once but may stand overnight. The method so modified is very much to be recommended. It gives more reliable results than the Darmstaedter HCl method. L. J. GILLESPIE.

Determination of the phosphoric acid soluble in citric acid by the iron citrate method. M. POPP. *Z. landw. Versw.* 18, 592-4(1915); cf. preceding abstract.—P. refers to the work of Z. and C. Care should be taken that the amt. of Fe present in the reagent is sufficient to prevent the pptn. of SiO_2 . 31.3 mg. Fe is sufficient for 0.5 g. Thomas meal. Though normal meals do not require H_2O_2 , some meals contain enough H_2S to give incorrect results if H_2O_2 is not used. L. J. GILLESPIE.

Determination of the phosphoric acid soluble in citric acid in Thomas meals by the iron citrate method. CELICHOWSKI AND FERD. PILZ. *Z. landw. Versw.* 18, 581-91 (1915); cf. *C. A.* 9, 2121.—C. and P. emphasize the need of pure substances and undecomposed solns. of H_2O_2 and citrate. The solns. of iron citrate, H_2O_2 , and magnesia mixt. are to be added to the citric acid ext. in the order named, without a long interruption in the process. A quick sepn. of the magnesia ppt. should be secured by stirring.

L. J. GILLESPIE.

The solubility of mineral phosphates in citric acid. G. S. ROBERTSON. *J. Soc. Chem. Ind.* 35, 217-20 (1916).—A series of expts. with some six different mineral phosphates, led R. to the following conclusions: The P_2O_5 is entirely sol. in 2% citric acid provided a sufficient number of exts. is made; the soly. increases somewhat with the degree of fineness of the material and diminishes upon calcining. The citric acid test is worthless as an indication of the value of phosphatic fertilizers to the plant and "there can be little doubt that as a source of P_2O_5 for the plant, rock or mineral, phosphates are just as valuable as basic slag."

C. F. MILLER.

Determination of potash in fertilizers. FERDINAND PILZ. *Z. landw. Versw.* 18, 77-108 (1915).—If a room can be kept free from NH_3 , a complete sepn. of the bases is unnecessary before a pptn. of K as $KClO_4$. The hot HCl soln. may be freed from H_2SO_4 by $BaCl_2$ (even 10% excess of this reagent hardly affects the result) and the K directly separated as the non-hygroscopic $KClO_4$. The ppt. is washed with 95 vol. % alc. containing 0.2% $HClO_4$. P. gives detailed directions for pure K and for other fertilizers and also tables for calcg. the results.

L. J. GILLESPIE.

The influence of fluorspar on the solubility of basic slag in citric acid. G. S. ROBERTSON. *J. Soc. Chem. Ind.* 35, 216-7 (1916).—In view of the fact that many basic slags now contain fluorspar (added to make them more fusible), R. carried out an investigation to det. its influence upon the soly. of the P_2O_5 by the so-called citric acid method (5 g. of material shaken for 30 min. with 500 cc. of 2% citric acid). The results showed that "the citric acid test gives no true idea of the soly. of the P_2O_5 in 'fluorspar slags' and affords no guide to its value to the plant." Although only a small % of the P_2O_5 was found to be available according to this method, from 90 to nearly 100% of the total dissolved when several extns. were made with 2% citric acid.

C. F. MILLER.

Experiments on the lime sensitiveness of lupines and its control. BODO CREYDT. *J. Landw.* 63, 125-91 (1915); through *Chem. Zentr.* 1915, II, 621.—Vegetation expts. led to the following conclusions: Lime sensitiveness of lupines is due to a specific aversion of the plants to CaO and not to a general alkali sensitiveness. The reason is to be sought in a strong power of the plant to dissolve and take up CaO . By addition of K_2CO_3 or KCl one can limit the one-sided Ca assimilation and to a certain degree moderate the injury done by Ca. Not only are the lupines directly affected by CaO but also indirectly through an unfavorable action on the nodule microorganisms.

L. J. GILLESPIE.

Nitrogen utilization in field and cylinder experiments. I. JACOB G. LIPMAN, HARRY C. MCLEAN, AUGUSTINE W. BLAIR AND LOUIS F. MERRILL. New Jersey Agr. Expt. Sta., *Bull.* 268, 5-25 (1915).—When sand was mixed with shale soil (Penn. loam) in varying proportions, the yield of dry matter and the % of N recovered from $NaNO_3$ were greater with 10 to 70% sand than they were with the shale soil alone, or with 80, 90 or 100% sand. The yield of dry matter and % of N recovered occurred with 50% sand. With 100% sand the yield of dry matter and the % N recovered were higher than with the shale soil alone. With the first crop the yield of dry matter and N were from the $NaNO_3$ cylinders

with the residual crop of buckwheat the highest av. yield of dry matter and N were from the dried blood cylinders. The fact that the av. yield of dry matter and N for the combined crops were about the same with NaNO_3 and dried blood does not necessarily lead to the conclusion that these 2 materials are equally good for all types of soil. It has been shown that for the shale soil, and dilns. up to and including 70% sand, the av. availability of dried blood is 70.6 when NaNO_3 is placed at 100, while, with 80 to 100% sand, the av. availability of dried blood is 250 when NaNO_3 is placed at 100. The av. % of N in the dry matter is higher for both crops with NaNO_3 than with dried blood or with the check cylinders. With most soils we need not expect much residual effect from NaNO_3 whereas we may from dried blood in nearly all cases. The actual net recovery of N from the humus of the shale soils to which varying amts. of sand had been added is greater in every case than the theoretical amt. as calcd. from the recovery from pure shale soil. Mixing sand with heavy soils permits better aeration and drainage and results in a more complete utilization of the N in the org. matter. It appears that the bacteria conveyed in small quantities of cow manure are instrumental in bringing about a more rapid decompn. of the green fertilizer crop and thus make available more N for the succeeding crop. If the green fertilizer crop consists of legumes, the additional N thus secured tends to obscure the effects of the manure.

R. C. ROARK.

Nitrogen utilization in field and cylinder experiments. II. JACOB G. LIPMAN, HARRY C. MCLEAN, AUGUSTINE W. BLAIR AND LOUIS K. WILKINS. New Jersey Agr. Expt. Sta., *Bull.* 281, 5-19(1914).—Expts. are recorded on the availability of NaNO_3 and dried blood when applied to shale soil and mixts. of sand and shale soil. NaNO_3 and dried blood when used on mixts. of sand and shale soil varying in proportion from 10 to 90% sand, give higher yields of dry matter and N in the 1st crop than when used with loam soil alone or sand alone. With the 1st crop nitrate invariably gave higher yields than dried blood, their availability being in the ratio 100 to 72.07. With the residual crop of buckwheat the yields from the check cylinders were in a number of cases larger than from the nitrate cylinders. With the combined crops the dried blood shows an availability of 85.66 when NaNO_3 is taken at 100.

R. C. ROARK.

Methods and results in vegetation experiments. JACOB G. LIPMAN AND AUGUSTINE W. BLAIR. New Jersey Agr. Expt. Sta., *Bull.* 269, 5-20(1914).—A wire cage for the protection of pot expts. is described with illustrations. As the result of pot expts. with both sand and gravelly loam, basic slag compares very favorably with other phosphates. A rock potash fertilizer containing 4.3% water-sol. K_2O gave lower yields than check pots, doubtless due to the formation of sol. toxic compounds. Expts. with radioactive material showed no appreciable effects one way or the other.

R. C. R.

Pot experiments on the availability of nitrogen in mineral and organic compounds. JACOB LIPMAN, HARRY C. MCLEAN, AUGUSTINE W. BLAIR AND LOUIS K. WILKINS. New Jersey Agr. Expt. Sta., *Bull.* 280, 5-23(1914).—The residual effects from the use of NaNO_3 are small, if the 1st crop develops normally, but are considerably increased where an excessive amt. of the nitrate depressed the yield of dry matter in the 1st crop. The residual effects from the use of organic nitrogenous materials are greater than the residual effects from NaNO_3 , but they are small when considered from the standpoint of the amt. of N that apparently remains in the soil after the removal of the first crop. Nitrogen applied in the form of NaNO_3 and org. matter, half the N from one and half from the other, gives a higher yield of dry matter and a higher recovery of N than N which is all in the form of organic matter. Applications of limestone ranging from 1 to 10% gave yields of dry matter which are more than double the yield without limestone and slightly in excess of the yield with NaNO_3 . With applications of limestone the % of N in the dry matter was not so high as with NaNO_3 but somewhat higher than without limestone.

R. C. ROARK.

Limestone and marl deposits of South Carolina. F. H. H. CALHOUN. South Carolina Agr. Expt. Sta., *Bull.* 183, 5-27(1915).—This bulletin records investigations made to locate the most available limestone and marl deposits of the state with special reference to those suitable for agricultural purposes.

R. C. ROARK.

The effect of organic compounds in pot experiments. G. S. FRAPS. Texas Agr. Expt. Sta., *Bull.* 174, 5-13(1915).—Impure dihydroxystearic acid has little injurious effect upon corn or sorghum grown in pot expts. when applied before planting at the rate of 500 parts per million of soil. In water culture expts. of other workers 10 parts per million injured the growth of seedlings. Vanillin and quinone applied to the soil at the rate of 100 parts per million of soil before planting injured the growth of only 1 of 8 crops. Vanillin and coumarone are oxidized in the soil, a considerable portion disappearing in 2 weeks and little remaining at the end of the pot expts. in which the tests were made. Six successive additions of coumarone, vanillin or quinone at the rate of 100 parts per million did not kill the plants. There was little evidence that fertilizers overcome the injurious action of these. Pyrogallic acid and carbon black showed no beneficial action in pot expts. while acid phosphate or other fertilizer are decidedly beneficial to the soils and produced decided increases. The conclusion is that these poor soils need the plant food supplied by the fertilizers and that the action of the fertilizer is to supply plant food and not to overcome toxic substances. Results of pot expts. may be quite different from results of water culture expts.

R. C. ROARK.

Effect of additions on availability of soil phosphates. G. S. FRAPS. Texas Agr. Expt. Sta., *Bull.* 178, 5-15(1915).—When N and K are supplied, the addition of CaCO_3 at the rate of 5 tons per acre increased the size of the crop and the amt. of P withdrawn from the soil phosphates on the 6 soils tested in the pot expts. The effect of the lime was small at first but usually increased with succeeding crops. The addition of starch, sawdust or cobs had some effect on the crop in 2 soils but little with the other 4 soils. The presence of CaCO_3 or of vegetable matter may bring about differences in the quantity of P assimilated by plants from soils containing equal quantities of active phosphoric acid. No relation can be traced between the additions and the P content of the crops. The phosphoric acid taken up by the plants was evidently drawn largely from the more insol. phosphates.

R. C. ROARK.

Limestones of New York with reference to their agricultural use. R. C. COLLISON AND J. F. BARKER. New York Expt. Sta., *Technical Bull.* 47, 3-38(1915).—A brief description of each of the 49 limestone formations found within the state of New York is given, together with results of analyses of samples of each. A limestone map accompanies the bulletin, showing the area of outcrop of each of the more important formations.

R. C. ROARK.

Potash. T. E. KERR AND C. J. KING. South Carolina Agr. Expt. Sta., *Bull.* 182, 3-16(1915).—The soil and crop requirements for potash and commercial and home sources are discussed. Analyses are presented of wood ashes, crop residues, plant materials not crop residues, such as marsh grass, mucks, and manures, showing content of K and other fertilizer ingredients. The liberation of soil potash by NaNO_3 , org. matter, gypsum and lime is discussed, and the conservation of all materials going to waste on the farm that contain plant food is urged.

R. C. ROARK.

Experiments with fertilizers. FIRMAN E. BEAR. West Virginia Agr. Expt. Sta., *Bull.* 155, 3-19(1915).—Fifteen years' expts. with fertilizers on different field crops are summarized. The value of manure is emphasized. Acid phosphate is a valuable crop producer and its use in liberal quantities is recommended. NaNO_3 and acid phosphate in combination gave 2.5 times as much increase per acre as acid phosphate alone; while K_2SO_4 in combination with these two gave 3 times as much increase per acre as acid phosphate alone.

R. C. ROARK.

Cotton-varieties and limiting factor tests. W. L. HUTCHINSON. South Carolina Agr. Expt. Sta., *Bull.* 185, 3-19(1916).—In 1914-15 N was the limiting factor for cotton and corn grown in succession, but for other seasons not so good, moisture may become the limiting factor. Detailed results of fertilizer treatment are presented in tabular form.

R. C. ROARK.

Miscellaneous insecticide investigations. E. W. SCOTT AND E. H. SIEGLER. U. S. Dept. Agr., *Bull.* 278, 1-47(1915).—Detailed results are given of spraying expts. with various arsenicals, kerosene emulsion, Bordeaux mixt., lead chromate, lime-sulfur, nicotine, soap, and various other substance, separately and in combination. Lead arsenate proved to be the most consistent and valuable stomach poison tested, and was equally effective in either the paste or powdered form. The triplumbic arsenate is less rapid as a poisoning agent than diplumbic arsenate, but is safer for use on tender foliage. Lead arsenate may be combined with nicotine, lime sulfur or kerosene emulsion. Lime sulfur and soap should not be combined, owing to the formation of an insol. Ca soap. The most promising new insecticide developed is Ca arsenate. R. C. R.

Relation of green manure to failure of certain seedlings. E. B. FRED. Univ. Wis. J. Agr. Res. 5, 1161-76(1916).—It was desired to det. why decrease of germination follows green fertilizing. A study was made of the effect of soil type, of increased aeration, temp., CO_2 , CaCO_3 and certain decompn. products on germination. Results indicated the injury was due to parasitic fungi, and oil seeds especially are damaged; starchy seeds are resistant. Germination of oil seeds is not effected if two weeks elapse after green fertilizing before planting. Small applications of CaCO_3 increase the injury.

R. O. E. D.

Utilization of the nitrogen of urine industrially. F. W. DAFERT AND ALFRED UHL. Z. landw. Versw. 19, 1-13(1916).—Utilization of the N of urine by means of micro-organisms proved impracticable: treatment of the urine with hot CaO promises better. The chief difficulty lies in the collection of the urine. D. and U. recommend a practical study at concn. camps.

L. J. GILLESPIE.

Talbot slag as fertilizer. O. REITMAIR AND TH. ALEXANDER. Z. landw. Versw. 19, 14-44(1916).—Phosphate meals from Talbot and from Thomas slag are of equiv. effectiveness in the field.

L. J. GILLESPIE.

New methods for analysis of lime-sulfur solutions. R. M. CHAPIN. J. Ind. Eng. Chem. 8, 151-6(1915); cf. C. A. 9, 686.—Methods are given for detg. the presence of excess base or excess acid and the concn. of both in solns. of lime-S. The methods are all based on the use of 0.1 N solns. titrated with lime-S solns. and measure the amts. of CaA_2 or M_2S_x . HCl soln. is used in detg. the sulfide base with methyl orange as indicator. For detg. the reaction figure 0.1 N I is mixed with 0.1 N $\text{Na}_2\text{S}_4\text{O}_6$ until color is nearly discharged, a little 0.1 N HCl is added to destroy iodate, and the soln. is titrated with 0.1 N $\text{Na}_2\text{S}_4\text{O}_6$. NH_4Cl soln. is added and one drop methyl red and titrated with 0.1 N NaOH. Equiv. difference between the alkali and acid solns. gives the "reaction figure." For sulfide-acid figure, method "A," algebraically subtract reaction figure from sulfide-base figure; method "B," the liquid from detg. the reaction figure contains thiosulfate exactly equiv. to M_2S_x originally present in sample. After addition of starch titrate with 0.1 N I and subtract from the result the thiosulfate titration; method "C" is applicable for dipping baths. It consists in titrating ammoniacal soln. of the sample with standard tetrathionate, using a 1% soln. NiSO_4 as indicator. Some of the methods offer promise of use in detg. H_2S or compds. of it in other materials.

R. O. E. D.

New methods for analysis of lime-sulfur solutions. II. Estimation of poly-sulfur. R. M. CHAPIN. J. Ind. Eng. Chem. 8, 339-41(1916); cf. C. A. 9, 686 and preceding abstract.—The S may occur in soln. as mono-S or as poly-S; general formula for Ca-

poly-S is expressed as $\text{Ca}(m - \text{S})(p - \text{S})_y$. The reaction $\text{Ca}(m - \text{S})(p - \text{S})_y + y\text{Na}_2\text{SO}_3 = \text{CaS} + y\text{Na}_2\text{S}_2\text{O}_3$ is the basis for the method. Mono-S is removed by ZnS and excess of sulfite as insol. Sr compd., after which thiosulfate is detd. by titration with I soln. From the total thiosulfate thus obtained must be subtracted the thiosulfate originally present in the lime-S soln. Details of carrying out the methods are given as well as notes on prepn. of solns. and certain precautions.

R. O. E. D.

Cactus solution as an adhesive in arsenical sprays for insects. M. M. HIGH. U. S. Dept. Agr., *Bull.* 160, 20 pp.(1915).—The work was undertaken for the purpose of discovering a good adhesive for use in arsenical sprays. This adhesive was found in cactus. It was demonstrated that it yields a high % of mucilaginous matter. Satisfactory results were secured with a mixt. of 15 lbs. cactus, 3 lbs. of Zn arsenate and 50 gal. of H_2O . A number of insecticides gave satisfactory results when used with cactus; the arsenical sprays were most effective. The chem. compns. of several varieties of cactus are given.

J. J. SKINNER.

Fate and effect of arsenic applied as a spray for weeds. W. T. McGEORGE. Hawaii Agr. Exp. Sta. *J. Agr. Research* 5, 459-63(1915); *J. Ind. Eng. Chem.* 8, 199 (1916).—Soils possess strong fixing power for As and when a Na_2AsO_3 spray is used for destroying weeds the As will ultimately be deposited in the surface soil, there to remain in spite of the leaching effect of rains or irrigation. The chem. reactions involved in the fixation are a replacement of soln. of Fe, Ca, Mg and humus, owing in part to a hydrolysis of the Na_2AsO_3 in soln., and to a combination with the dibasic and tribasic elements to form the difficultly sol. arsenites or arsenates.

W. H. FRY.

Potash from kelp (LAUCKS) 18. The question of the commercial monopoly of nitrogen (v. MARTIUS) 18.

Fertilizer. S. B. NEWBERRY and H. N. BARRETT. U. S., 1,174,176, Mar. 7. A mixt. of natural Ca phosphate with 10-25% of NaCl or KCl is calcined at a temp. which is gradually raised nearly to a white heat, in an atm. of combustion gases rich in SO_2 and H_2O vapor (produced by burning fuel rich in S). The chloride is first decomposed to sulfate with formation of HCl and the sulfate is then decomposed at a higher temp. with liberation of SO_2 . A residue of porous fragments of phosphate nearly free from chlorides, or sulfates is obtained.

16. FERMENTED AND DISTILLED LIQUORS.

ROBERT WAHL.

Longevity of artificial cultures of wine yeasts preserved in a ten percent sugar solution. R. MEISSNER. *Z. Weinbau. Weinbehandlung* 2, III, 103-7(1915); *Bull. Agr. Intelligence* 6, 1234-5(1915).—Among 25 cultures of yeast stored for 13 years in a 10% sugar soln., 12 strains of yeast had lost none of their fermentative power. One of these showed a greater activity than the cultures which had been kept fresh by transplantation. The expts. are being continued.

L. W. HAAS.

Experiments on vinification in a sulfurous medium with and without selected ferments. G. DALMASSO AND L. SUTTO. *La rev. viticoltura, enologia agraria* 21, 385-93(1915); *Bull. Agr. Intelligence* 6, 1525.—The must was placed in 5 vats of equal capacity, one was used as a control and the others treated in the following manner: (1) with "biosulfite Jacquemin," (2) with KHSO_3 , (3) with "biosulfite Jacquemin" and "multilevures Jacquemin."

-t of this expt

"multilevures Jacquemin" alone. The chief
the two methods is to be preferred when "oxi-

dasic break" (casse) or "turn" occurs in a wine. The following conclusions are drawn: The sulfitation method is always the most economical and the most certain for obtaining spontaneously limpid white wines and is a certain preventive of oxidasic break, and malolactic fermentation. These expts. show no special advantage from the use of "biosulfite Jacquemin" in place of the ordinary KHSO_5 . No advantage was found in the use of selected ferments. In the absence of SO_2 they did not give favorable results in this particular expt., but this does not mean that they have no useful functions in modern wine-making. On the contrary, selected ferments have been of great use in the vinification of grapes damaged by hail, diseases and insects. L. W. HAAS.

Shortened determination of extract in barley. L. HEINTZ. *Wochenschr. Brau.* 33, 65-7(1916).—H. uses for ext. detns. the cleaned barley or the portions retained by the 1st and 2nd screen of the screening app. The ext. is detd. as follows: 25 g. of fine barley meal are mashed in with 75 cc. malt infusion (200 g. light malt, finely ground, are digested for 10 min. with 1 l. distd. water at 45° , filtered through 3 filters, and then cooled) kept for 1 hr. at 50° , then heated quickly to 70° . After 15 min. 20 cc. distd. water at 70° is added and the mash held at 70° for 15 min. longer; the water in the bath is then heated to boiling, and maintained for 15 min., cooled to 70° , 25 cc. malt infusion added and the mash after being held at 70° for 15 min. more, cooled, weighed up to 225 g., filtered and treated in the usual manner. The method is claimed to give very satisfactory results; the time for a detn. is reduced from 22 to 4 or 5 hrs. L. W. H.

The spirits and spirits preparations industries in the year 1914. H. RÜDIGER. *Chem. Ind.* 38, 485-500; 533-45(1915).—A review. F. W. SMITHER.

New scientific conceptions and their application to quality and methods of preparing beer. R. WAHL. *Am. Brewers' Rev.* 29, 271-4, 365-8, 557-9(1915).—The importance of the H^+ concn. for brewing, the significance of colloidal matter for chill-proofness of beer and the usefulness of the electronic conceptions in disclosing the structure of matter are demonstrated and discussed. L. W. HAAS.

New use for dried potato-pulp. E. PAROW. *Z. Spiritusind.* 39, 67(1916).—On account of its moisture-bonding properties, dried potato pulp may be used for preservation of products high in moisture (as grated potatoes and beets); these then may be worked into durable fodder which also may serve as raw material for technical industries (distilling, yeast and lactic acid manufacture). When grated potatoes and dried pulp are mixed in equal quantities the product may be pressed into solid briquets without the loss of water. These briquets rapidly dry out (the water content of 44.8% of the fresh mixt. decreased to 17% in the briquets exposed to air for a few days), and represent a hard, durable and easily transportable feed. Molasses, fodder yeast or other feed-stuffs may be incorporated. L. W. HAAS.

Sucrose in grapes of American origin (GORE) 12. Sucrose in relatively large amounts in a new seedling grape (ALWOOD) 12.

Purifying yeast. P. KNOBLAUCH. *Ger.*, 286,180, Apr. 25, 1914. An app. is provided on fermentation vats for removing impurities from the yeast.

Pressed yeast. J. EFFRONT and A. BOLDIN. U. S., 1,176,528, Mar. 21. Cooked maize or other grain is liquefied by treatment with a small amt. of malt at about 75° , cooled to 40° , rendered slightly alk. and strongly aerated after the addition of peptonizing bacteria. The fermentation is stopped when the greater part of the nitrogenous substances are rendered assimilable and the product is heated to $62-4^\circ$ and saccharified by the malt. The bacteria used are acclimatized previously to alk. and aerated solns.

Denatured alcohol. J. W. KENEVEL. U. S., 1,176,462, Mar. 21. Products of

destructive distn. of wood or other organic matter are distd. with alc. from fermented vegetable matter and the distillate is rectified to remove substances boiling at temps. either much above or much below the b. p. of alc.

Denatured alcohol. J. W. KENEVEL. U. S., 1,176,150, Mar. 21. Products from the destructive distn. of straw, flesh, bone, lignite, coal or wood, after being freed from gases and constituents boiling at 100° or higher, are mixed with fermented alcoholic mash and the mixt. is distd. and rectified to produce denatured alc.

Mannitol from natural musts. G. P. GUIGNARD. U. S., 1,175,747, Mar. 14. Natural musts are inverted, neutralized, sterilized and concd. until they contain at least 15% levulose and are then acted on with a mannitol ferment which has been acclimatized to a must of this concn. The alc. produced is distd. off, the remaining vinasse is desiccated and washed with cold alc. satd. with mannitol, the alc. is evapd. from the soln. thus obtained and the residue is dissolved in H₂O, treated with FeSO₄ to form Fe lactate and acetate and CaSO₄, evapd. to dryness and the mannitol is extd. with hot alc. and pptd. by cooling.

Preserving must. JEAN-AUGUSTE DEJEANNE. Fr., 477,953, July 8, 1914. The fruit is not crushed nor expressed until freed from microorganisms which generally are found upon the outer skin of the fruit. This is effected by means of suitable sterilizing agents.

A protective lining for metal tanks for transporting beer. WICKÖLER-KÜPPER-BRAUEREI AKT.-GES. Ger., 285,795, Dec. 14, 1912. The inner surface of the container is coated with one or more layers of lacquer, burned in, and upon this is applied a layer of pitch. Before lacquering the surface may be tinned. Cf. C. A. 9, 1849.

Apparatus for testing wort. G. BANZER, R. HALDER and A. STADLER. Ger., 283,593, Nov. 27, 1913. The app. is devised for testing the wort as it flows from the acid vat.

17. PHARMACEUTICAL CHEMISTRY.

M. I. WILBERT.

A new color reaction for aloes. C. E. STACY. *Analyst* 41, 75(1916).—A pink coloration sufficiently delicate to detect one part of Barbadoes aloes in 10,000 is produced in 5–15 min. by the addition of a freshly prepd. soln. of K₃Fe(CN)₆ to the cold aq. soln. of aloes. If excess of either test soln. or reagent is employed, no color is produced. The color is permanent, and is rendered apparent more rapidly by heating just to boiling. Minute quantities of the reacting substances are removed by petroleum ether, C₆H₆, CHCl₃, but none by ether or AcOEt. After removal of the ordinary principles of aloes (aloin, emodin, etc.) the bulk of the reacting material remains. In 10% solns. the color is blood-red. Socotrine and Cape aloes and commercial aloin give an emerald-green color. No reaction is given by *Cascara sagrada* or rhubarb. The color is destroyed by acids and large amts. of alkali. Small amts. of alkalies intensify the reaction and introduce a brown color.

P. B. DUNBAR.

Neurokardin. C. MANNICH AND F. SCHIRMER. Univ. Goettingen. *Apoth. Ztg.* 31, 79(1916).—According to the analytical findings this alleged nerve tonic consists of an artificially colored red aq. ext. of Kava root, stabilized with salicylic acid.

W. O. E.

Estimation of the oxychloride and free hydrochloric acid in ferric chloride solutions. K. FEIST. *Arch. Pharm.* 253, 451–6(1915).—A discussion of Romijn's expts. (cf. C. A. 9, 1971, 2285) on this subject, as also the Pharm. tests for the prepn., particularly the Na₂S₂O₃ test.

W. O. E.

Bismuth *o*-acetoxybenzoate. L. VANINO AND FR. MUSSAGNUO. *Arch. Pharm.* 253, 511-2(1915).—On adding a concd. aq. soln. of 16 g. Bi nitrate and 6 g. mannitol to a soln. of 20 g. $\text{AcOC}_6\text{H}_4\text{CO}_2\text{Na}$, the salt, $\text{C}_{27}\text{H}_{21}\text{O}_{12}\text{Bi}$, is pptd., easily sol. in acetone and AcOH , difficultly sol. in CHCl_3 and C_6H_6 , insol. in alc., Et_2O and petr. Et_2O . It is easily decomposed. W. O. E.

Croton resin. R. BOEHM. Univ. Leipzig. *Arch. Pharm.* 253, 574-85(1915); see C. A. 10, 497. W. O. E.

Simplification of the exact fatty acid determination in *sapo kalinus*. E. WENDE. Univ. Koenigsberg. *Arch. Pharm.* 253, 585-9(1915).—Weigh out 2 g. thoroughly mixed sample on a piece of parchment paper, roll the latter and introduce into a 100 g. medicine bottle. Add about 50 g. hot H_2O and agitate until soln. results, then acidify with 10 g. dil. H_2SO_4 and heat on the vapor bath until the fatty acids are completely pptd. Add to the cold mixt. about 20 g. benzine (petr. ether), close bottle and agitate until the fatty acids are dissolved, then invert the container and by carefully opening it withdraw all but about 2 g. of the aq. liquid. To the residual contents of bottle add 0.5 g. powdered tragacanth and by means of about 20 shakes separate the fatty acid soln. from the resulting jelly. Pour the clear benzine soln. into a weighed Soxhlet flask, washing the jelly with 3-5 cc. portions benzene. Evap. the united solvent portions on a vapor bath, drying the residue to const. wt. at about 80° . The wt. of fatty acids thus obtained should amount to at least 0.8 g., corresponding to a minimum content of 40% fatty acids. W. O. E.

Lemon oil. A. H. BENNET. *Boll. della Camera Agrumaria*, 1, Pt. 5, 23-4(1915); *Bull. Agr. Intelligence* 6, 1248-9(1915).—The factors concerned in the valuation of essence of lemons are citral content, d. and opt. rotation. While the citral content is a real indication of the quality of the essence, B. considers the rotation of less value as a diagnostic factor. A minimum of 58° would exclude from the market all the richest essences of the Messina district, while a minimum of 61° (Australian law) is reached by only a small proportion of the production which, according to other standards, is not of the best quality. On the other hand the rotation standard was justifiable when the essence was most commonly adulterated by turpentine, which lowered the index of rotation. This fraud is now easily detected by other tests; hence other means of adulteration are practised such as addition of terpenes obtained from the prepn. known as "essence without terpenes" or addition of refined fixed oils (as white vaseline, etc.) which are easily recognizable. Furthermore, a high citral content is generally accompanied by a low rotation and this year's crop is characterized by an exceptionally high % of citral. B., therefore, recommends the establishment of a minimum for citral content, and in place of a standard for the rotation, adopting the surer tests for purity. Expts. have been started on the keeping qualities of the essence under different conditions. The results obtained after 3 months with (a) unfiltered essence stored in Cu, (b) filtered essence stored in Cu, (c) filtered essence stored in glass, in each case not freed from moisture, and (d) with dried essence in contact with Na_2SO_4 , have shown that there is no remarkable change and only a small decrease in citral content. Expts. are being continued to study any possible changes due to the warmer months of the year. W. O. E.

Change of methyl alcohol by the addition of essential oils. ROBERT BUNESTEN-BINDER. *Deut. Parfumerie-Ztg.* 1, 32-3(1915).— MeOH is not inherently toxic but becomes so only through the formation of CH_3O and HCOOH . Since the addition of essential oils promotes oxidation, MeOH should not be employed in the prepn. of schnaps. W. O. E.

Chemical changes in resweating of seedleaf tobacco. H. R. KRAYBILL. *J. Ind. Eng. Chem.* 8, 336-9(1916).—The principal results of the investigation are summarized as follows: (1) The greatest loss of dry matter during the resweating process

occurs in the proteins, nicotine, H_2O ext. and N-free ext. The total N, NH_3 , HNO_3 , and crude fiber show slight losses. (2) The amides and reducing substances show an increase. (3) The changes during the resweat are quite similar to those of the first sweating process. It seems, therefore, that the resweat is a continuation of the first sweating process. The changes during the resweat seem to be greater than during the first sweat, but this is what we should expect because the resweating process is more severe. (4) The loss in protein N minus the gain in amide N is 0.06% and this plus the loss in NH_3 (0.09%) and HNO_3 N (0.18%) equals 0.32%. The total loss in N is 0.61%. The difference between the total loss of N and the loss of N as HNO_3 , NH_3 , and amides (loss of protein N minus amide gain in N) is 0.28%. It appears from this that the most of the nicotine which is lost, is lost by volatilization. This is in accord with the results of Garner. (5) It is evident that a breaking down of proteins into amides occurs. From this we can readily see that there is probably an enzyme present which is capable of breaking down the proteins. (6) Since the increase in amide N is not so great as the loss in protein it suggests that there may be present a ferment which breaks up the amino acids, although no definite conclusions can be drawn. (7) The total loss of org. matter in the leaf samples was 11.11% and in the midveins 2.32%. Behrens reports a loss of 5.6%. (8) The changes in the midveins are similar to the changes in the leaf but are not so great.

W. O. E.

Comparison and identification of various types of smoking opium. F. D. SIMONS. *J. Ind. Eng. Chem.* 8, 345-51 (1916).—The exptl. work comprized an examn. of the following samples: (1) Two samples of raw Smyrna opium imported through the port of Baltimore; partly dried when exptd. with. (2) Aq. exts. of duplicate samples of the above; made in conformance to the directions given for the former U. S. P. ext. of opium (moist). (3) Insol. residues left after making the above exts. (4) Tschandu (not fermented) prepd. in the laboratory from duplicate samples of the raw opium ((1) above) and as nearly as possible in accordance with the method already described. (5) Exhausted residues (from which ching ko is extd.) obtained in the prepn. of the tschandu ((4) above). (6) Two samples of smuggled opium, representing a seizure made by U. S. Customs officers at Baltimore, of a number of cans of smoking opium. The cans, weighing about 5 taels ($6\frac{2}{3}$ oz.) each, bore labels inscribed with Chinese characters, and may or may not have been manufactured in China. (7) One sample of yen shee; the residue and ext. examd. separately. (8) One sample of moist ext. of opium prepd. by a manufacturing chemical company for medicinal use; dried somewhat. (9) Average of 4 samples of regularly imported Smyrna opium. *Summary of tests:* To det. whether samples of type (1) were manufactured for medicinal use or prepd. solely for smoking purposes, dependence must be placed upon the H_2O content, which, while its line of demarkation between the 2 classes is very faint, still can afford the basis for comparatively reliable judgment. In the case of "moonshine" ext. of opium, however, a decided variation of the morphine content from the 20% requirement of the Pharmacopoeia should be valuable circumstantial evidence in support of an opinion. Samples of type (2) are partly demonstrated by the proportion of morphine found in the total alkaloids, and may be conclusively identified by the practical absence of codeine, papaverine and narceine, and the diminished amt. of thebaine in the smoking opium under examn. The ratio of morphine to total alkaloid for tschandu should lie between 1:1.11 and 1:1.50, and the amt. of morphine should never be less than $\frac{2}{3}$ of the entire alkaloid content. For the ext. of the unroasted opium the ratio should vary between 1:1.50 and 1:2+, and the proportion of morphine should naturally be the reverse of that for tschandu. Samples of type (3) will show an abnormal alkaloid compn. similar to that of tschandu; this, however, may be moderated or exaggerated, depending on whether yen shee was added to the ordinary ext. or to tschandu. Suspicion will also be directed toward a

sample when its ash % exceeds 8.0, or its H_2O -insol. residue (consisting largely of C. exceeds 5.0 in the dry material. The peculiar and characteristic odor of *yen shee* may also furnish a clue if noticed in the smoking opium. Samples of type (4) may be identified by the usual physical, chem. and microscopic tests. W. O. E.

Terpacid and its preparations. I. SCHLESINGER. *Klin. Ther. Wochenschr.* 21, No. 48-9(1915).—Terpacid (fenchone), $C_{10}H_{18}O$, the synthetic oxidation product of fenchyl alcohol, is a very mobile liquid having a camphor-like odor and a bitter burning taste, easily sol. in most org. solvents, d. 0.95, b. $193-6^\circ$. Its use as a substitute for camphor is recommended. W. O. E.

Enesol. HANS SCHMIDT. *Pharm. Ztg.* 61, 107(1916); cf. C. A. 10, 951.—This prepn. contains mercuric salicylate and Me arsonic acid in alk. soln., the content of the Hg compd. being not quite half as great as stated by the mfr., while that of As is twice as great. W. O. E.

Report of Chemists Sub-Committee on Standardization and Drug Testing. F. P. SUMMERS, et al. *8th Ann. Meeting Am. Assoc. Pharm. Chem.*, 1915.—The report, among other things, presents data covering a considerable number of tests on tablets made with single, double and multiple punch machines, and offering suggestions and explanations relative to the variations observed. Comments are likewise made on the prepn. of pepsin tablets, as also on the methods in vogue for the assay of pepsin. Finally, assay methods for surgical dressings (gauzes) and opium prepn. are discussed. W. O. E.

Testing water intended for salvarsan solutions. J. TILLMANS AND H. MILDNER. *Z. angew. Chem.* 28, I, 469-74(1915).—The chief results of the investigation are summarized as follows: (1) Water intended for the prepn. of salvarsan solns. may be contaminated in one or all of 3 ways, namely, presence of bacteria, glass constituents and heavy metals. (2) Detn. of the first named contamination is largely a bacteriological question. Bacteriological testing, however, should be amplified by a detn. of the reducing power with respect to $KMnO_4$, as also the detection of NH_3 and HNO_3 . Detn. of the reducing power must be subjected to more careful scrutiny than heretofore, to which the following procedure is suggested: Measure off 100 cc. of the sample into an Erlenmeyer, add 5 cc. dil. H_2SO_4 (1 + 3) and run in from a buret (graduated to 0.05 cc.) 8 cc. 0.01 N $KMnO_4$. Heat to boiling on wire gauze exactly 10 min. (counting from the time it begins to boil), then add 10 cc. 0.01 N oxalic acid and agitate the liquid, finally titrate the excess of oxalic acid (above that required to offset the $KMnO_4$ with 0.01 N $KMnO_4$. For purposes of control, measure into a Jena beaker 200 cc. distd. H_2O , 10 cc. dil. H_2SO_4 (1 + 3) and 2 drops 0.01 N $KMnO_4$, then heat to boiling on wire gauze. If the red color disappears, add another drop and boil. Continue to add the reagent and boil until a pink color persists. Of this soln. take 100 cc., transfer to an Erlenmeyer as in the main expt., repeating the operations above prescribed therefor. The total amt. expended $KMnO_4$ ascertained for the control is subtracted from that found in the main expt. A distd. H_2O yielding a difference of more than 0.2 cc. 0.01 $KMnO_4$ between main expt. and control contains appreciable amts. of org. matter and hence should be rejected for salvarsan injection. (3) Detection of glass constituents can be effected by treating the boiled distd. H_2O with rosolic acid, which in the event of the presence of glass constituents develops a reddish color. This test becomes illusory only with the simultaneous presence of tap H_2O , an event easily detd. through qual. tests for Ca, Cl or HNO_3 . (4) Of heavy metals which might possibly come in contact with distd. H_2O and, therefore, contaminate it is Fe, which, however, must be regarded as harmless. Of the other metals Sn may be disregarded for the reason that it is not dissolved by distd. H_2O . (5) The presence or absence of Pb, Cu, Ni and Zn is demonstrated by the application of an analytical scheme involving specific reactions

For each metal. Water containing either one of these 4 metals should not be used in salvarsan medication. W. O. E.

Cassia and cinnamon barks. E. M. HOLMES. *Perf. Essent. Oil Record* 7, 14-7, 41-3(1916).—A discussion of the sources, characteristics, and chem. constituents of different cassia and cinnamon barks. C. O. EWING.

Bay oil experiments in Montserrat. ANON. *Perf. Essent. Oil Record* 7, 34-5 (1916).—It has been found that a better quality of bay oil, with higher d. and phenol content, is obtained by continuing the distn. for 9 hrs. instead of the usual 6 hrs. A table shows the yield of oil per hr., with the phenol content and d. of each fraction. With regard to keeping quality, a sample kept on a shelf for 2.5 years had not changed in phenol content, but there was a slight rise in d. due probably to polymerization of myrcene, which is an important constituent of bay oil. C. O. EWING.

Optical rotation of camphor in alcoholic solution. J. C. UMNEY. *Perf. Essent. Oil Record* 7, 46(1916).—The highest $[\alpha]$ for camphor ($+42^{\circ} 20'$) was obtained with a weak soln. (5%) in strong (90%) EtOH. The $[\alpha]$ diminished as the EtOH was replaced by H_2O , and also diminished in the same concn. of EtOH as the concn. of camphor was increased. C. O. EWING.

Oil of Eucalyptus macaurethuri. J. C. UMNEY. *Perf. Essent. Oil Record* 7, 46 (1916).—This oil is remarkable for its high % of geranyl acetate. Analysis: d. 0.926, $[\alpha] -2^{\circ}$, esters as geranyl acetate 66.7%, total geraniol 76.3%, sol. in 3 vols. EtOH. Neither phellandrene nor eucalyptol were detected but a small amt. of pinene was present. The price is too high to make the oil of commercial importance. C. O. EWING.

Sapo Medicatus and Sapo Kalinus of the German Pharmacopoeia. PRESCHER. *Pharm. Zentralhalle* 56, 611-3(1915).—In the prepn. of Sapo Medicatus, equal parts of mutton tallow and peanut oil are recommended in place of lard and olive oil which are now very high in price, as are also other possible substitutes such as palm, cottonseed and sesame oils. In the prepn. of Sapo Kalinus, the use of alcohol is not necessary, the glycerol formed during the saponification serving the same purpose. Calcined soda which gives a clear soap can be substituted for K_2CO_3 . C. O. EWING.

Cholic acid and some of its preparations. R. WERNER. *Pharm. Zentralhalle* 56, 591-4(1915).—A review, with bibliography, of cholic acid and some of its important pharm. prepn. C. O. EWING.

The use of talc in dermatology. P. ROHLAND. *Pharm. Zentralhalle* 56, 575-7 (1915).—Talc possesses a strong adsorptive power for color substances, colloidal solns., fats and oils, and strong odors. This property makes it useful in dermatology. The adsorptive power can be detd. by shaking 10 g. with 100 cc. of a soln. of methylene blue of definite concn., filtering and detg. colorimetrically the amt. of dye left in the filtrate. Cf. C. A. 9, 3288. C. O. EWING.

Cleaning and sterilizing of glass medicine containers and laboratory apparatus. A. G. BARLADÉAN. *Pharm. Zentralhalle* 56, 631-7(1915).—A discussion, with an extended bibliography of the advantages and disadvantages of the well-known methods of cleaning and sterilizing medicinal and chemical glassware in the lab. The best method is to rinse with steam. For this purpose a simple app. consists of a flask fitted with a funnel, within the neck of which is a cork carrying a tube. H_2O , made slightly alkaline to fix CO_2 , is boiled in the flask. The steam passes up through the tube and condenses on the sides of the vessel to be cleaned which is inverted over the tube and drains down into the funnel. C. O. EWING.

Purification and physiological action of animal charcoal. A. G. BARLADÉAN. *Pharm. Zentralhalle* 56, 683-7(1915).—Com. animal charcoal contains some uncar-

bonized org. material. Before being administered internally it should be carbonized again. Maceration in distd. H_2O will remove many sol. impurities. Boiling in concd. NaOH and then in concd. HCl removes some others. When the charcoal was carbonized and treated with concd. NaOH and concd. HCl daily for two weeks, some material was still taken up by a nutrient soln., as shown by germination expts. with wheat.

C. O. EWING.

Peppermint tablets for diabetes sufferers. C. A. HUBER AND P. VAN DER WIELEN. *Pharm. Weekblad* 52, 865-7(1915).—The tablets prepd. by the authors have the following compn.: Levulose 10, Olei Menthae pip. gtt. I, Sol. Gelatinae 20% q. s., M. F. trochisc. Nr. 20.

P. v. d. M.

Reduction of bismuth nitrate. A. ROBERTSON. *Pharm. Weekblad* 52, 945(1915).—The blackening of a prepn. which contained NaBr, Mag. bismuthi, water, and sugar, in the sunlight was found to be due to the formation of metallic Bi. The acid reaction of the Bi salt brings about inversion of the sugar, which then causes reduction. The reduction also takes place in the absence of water, but the presence of the Br salt is essential.

P. VAN DER MEULEN.

The fat of nux vomica. H. E. WATT AND G. B. ANGUS. *J. Soc. Chem. Ind.* 35, 201(1916).—Nux vomica contains 1-2% of a concrete oil or fat which consists principally of the glycerides of capric, caprylic, caproic, butyric and palmitic acids. The unsaponifiable matter consists of a satd. alc. $C_{25}H_{51}OH$, and an unsatd. alc. $C_{25}H_{49}O_5H_2O$ behaving like syroceryl alc. The oil is dark brown in color and possesses an unpleasant odor. An analysis gave: $d_{16.6}^{100}$ 0.892, sol. point 60° , sapon. no. 152, I no. (Hübl) 54, Reichert-Wollny no. 1.0, acetyl no. 31.2, acid no. 33.7.

E. A. TSCHUDY.

Goa ipecac root. LÉCOQ. *Bull. des Sci. Ph. Sep.*, 1915; *Schweiz. Apoth. Ztg.* 53, 695(1915).—The root of *Naregamia alata* (Meliaceae), a small plant occurring in Travancore and near Goa, is very aromatic, bitter, reddish yellow and is sometimes used as an adulterant of ipecac root. Aside from being different in appearance, it is rich in oleoresin. It also contains an alkaloid, naregamine (Hooper, 1887), which differs from emetine by readily forming acicular crystals with acids. A tincture prepd. from this root has been successful in dysentery, and as an expectorant, being non-toxic, and harmless towards the digestive and urinary organs.

S. WALDBOTT.

The tonka bean. EDWARD ALBERS. *Bull. Pan-American Union; American Perfumer; Midland Druggist* 50, 109-13(1916).—A descriptive account, with photographic illustrations.

S. WALDBOTT.

Assay of folium and extractum belladonnae and hyoscyami. JOHANNESSEN. Copenhagen. *Farmaceutisk Tidende; Schweiz. Apoth. Ztg.* 53, 730-4(1915).—For *Folium belladonnae*, J. replaces the EtOH extn. method of the Pharm. Helv. IV by the following "water" method: Macerate 15 g. of powdered leaves for 24 hrs. with 145 g. of 0.1% HCl, filter and evap. 60 g. of filtrate (= 6 g. of leaves) on water bath to about 5 g. Rinse into a bottle with 7 g. of H_2O , treat as in Pharm. Helv. IV with Et_2O 90 g., and NH_4OH 3 cc., filter 75 g. soln. through cotton, wash with 3×5 cc. Et_2O and evap. Add 30 cc. Et_2O , 25-40 cc. H_2O and 3 drops of iodoeosin, then a definite excess (10-20 cc.) of 0.01 N HCl and titrate back with 0.01 N NaOH. The H_2O used in the prepn. of the solns. must be strictly neutral, as iodoeosin is a very sensitive indicator. In Table I, a summary of 16 detns. is given. The alkaloids vary from 0.354 to 0.601%. The method of the Pharm. Helv. IV and the "water" method give the best results; that of Caesar and Loretz (*Jahresb.* 1913, i. e., maceration of leaves with Et_2O and NH_4OH) is useful in experienced hands; the method of the German Pharm. 1910 is inexact and tedious owing to emulsions; the results with the method of the new Norwegian Pharm. are too low. Shaking-out expts. with pure atropine

show that direct titration and shaking-out from NH_4OH soln. with CHCl_3 (Caesar and Loretz) give exact results. For *Folium hyoscyami*, J. recommends his "water" method. The results of 16 detns. are given in Table II. The alkaloids vary from 0.017 to 0.038% (German Pharm. standard 0.07%; cf. Anselmino and Gilg, *C. A.* 8, 778). For *Extractum belladonnae*, the method of H. Thaysen (*Archiv for pharm. og kemi*, 1910) is recommended. 4 g. of ext., 75 g. H_2O and 10 drops of dil. HCl are warmed on a water-bath, the mixt. is cooled, weighed (giving a total of 80 g.), and filtered. 65 g. (= 3.25 g. ext.) of the filtrate are evapd. to 13 g. 12 g. thereof are treated as in Pharm. Helv. IV. Care must be taken that the chlorophyll seps. in fine division, not in lumps. The amts. of alkaloid found were 1.162–1.688%. For *Ext. hyoscyami*, H. Thaysen's method was again used; 18 exts. gave 0.116–0.341% alkaloids. To standardize exts., Beuttner's method is followed, i. e., the percolate is evapd. somewhat, examd. for alkaloids and dry residue, the calcd. amt. of lactose is added and the mixt. evapd. to the proper wt. *Ext. belladonnae siccat.* was assayed as follows: 6 g. dry ext. are macerated for 1 hr. with 57 g. of 0.2 *N* HCl and filtered. To 42.5 g. of the filtrate are added 7 cc. *N* NaOH and the mass is evapd. to 8.5 g. Shake 8 g. with 60 g. of Et_2O and 3 g. NH_4OH . 45 g. Et_2O soln. (= 3 g. of dry ext.) are treated further as usual. The results were concordant. *Ext. hyoscyami siccat.* was assayed similarly. The addition of licorice seems to influence the alkaloidal content. J. found in ext. of licorice root with K_2BiI_6 a faint reaction, possibly of an alkaloid. S. WALDBOTT.

Some experiments with proposed formulas for camphor ice. CURT P. WIMMER. *Midland Druggist* 50, 63–5 (1916).—After a discussion of an old formula by Septimus Piesse (1856) and 7 proposed subsequently, W. gives the following basic formula: White mineral oil 20, paraffin 20, spermaceti 5, camphor 20. The resulting prepn. has a cryst. surface, is semitranslucent, like ice, has the proper consistency, and the cooling action of camphor. The addition of white wax, lard, suet or vegetable oils tend to affect color and transparency and to impair the keeping quality of the prepn.

S. WALDBOTT.

Laboratory notes. RAPP. *Pharm. Ztg.* 1915, No. 45; *Schweis. Apoth. Ztg.* 53, 721–3 (1915).—The manufacture of Et_2O and of CHCl_3 for anesthetic purposes, and the prepn. of zinc rubber plaster are included.

S. WALDBOTT.

Ambergris. BRUFF. Christiania. *Tidskrift f. kemi, farmaci og terapi* 1915, 125; *Schweis. Apoth. Ztg.* 53, 729 (1915).—Lumps weighing from 0.5 to 75 kg. occur in Norway commerce. Genuine samples have low sapon. no., show concentric layers of dark and light colors, yellow gray to brownish black, and contain the horny gills of a cuttlefish species which serves as food for the whale. At 60° where it is said to melt, it becomes ointment-like, but melts at a higher temp. B. found d. = 0.950 instead of 0.908 to 0.920. Sapon. no. 17, 19 and 35 in 3 expts.; ash only traces. It is used in perfumery as a fixative for other aromatics, and is liable to be adulterated with tallow, gum benzoin, olibanum, etc.

S. W.

Artificial lanolin and "Pommade Bourget." E. ANSELMIER. *Schweis. Apoth. Ztg.* 53, 736–7 (1915).—A mixt. of yellow wax, 0.3, solid paraffin 0.7, yellow vaseline, 9.0, preferably "Chesebrough" or "Wilburine," is useful as a substitute for lanolin, which is scarce. "Pommade Bourget" which lends itself well to mixts. with other medicaments, contains $\text{C}_6\text{H}_4\text{OHCO}_2\text{H}$ 10.0, oil of turpentine 10.0, tallow 70.0, yellow wax 2.5, and solid paraffin 7.5.

S. WALDBOTT.

Camphor and camphor oil. B. J. EATON. *Agr. Bull. Fed. Malay States* 3, 403–4 (1915).—In connection with expts. on the prepn. of camphor from the Japanese camphor tree *Cinnamomum camphora* samples of camphor and of camphor oil were sent to the Imperial Institute, London, for further investigation and valuation. Two sam-

ples of camphor oil were found to have the following consts., resp.: d_{44}^0 0.913, 0.900; $[\alpha]_D^{41}$ 1' at 18°, 38° 23' at 22°. Camphor content on cooling to -10°, to -12° 19.3%, 12.8%. An interesting feature of both samples is the absence of safrole, due it was supposed to the fact that the distillate was obtained from young twigs and leaves, whereas the ordinary Japanese camphor oil is derived from old wood and mature trees. The crude camphor was submitted to a firm of commercial experts who reported that it was very similar to Chinese "leaf" camphor and would be readily saleable in London.

M. I. W.

Oil of Strophanthus and the emetic action of strophanthus. ROBERT A. HAYCORN. *J. Am. Pharm. Assoc.* 5, 157-62(1916).—Strophanthus contains a fixed oil but the suggestion that this oil is responsible in part at least for the nausea and vomiting occasionally seen after the therapeutic use of the tincture has not been proved. It has been shown conclusively that all of the digitalis compds. induce nausea and vomiting through the action on the vomiting center and the emetic action of oil of strophanthus is largely, though not entirely, due to the fact that the oil usually contains traces of strophanthin. Oil of strophanthus freed from strophanthin is apparently capable of causing nausea and vomiting when administered to cats in doses of 850 mg. per kg. The tincture of strophanthus contains only traces of fixed oil and the average therapeutic dose of the tincture contains an amt. of the oil corresponding to less than 1/100 of that required to cause nausea and vomiting in the cat relative to weight.

M. I. W.

The rapid separation of heroine and morphine. JAMES M. DORAN. *J. Am. Pharm. Assoc.* 5, 163-5(1916).—The usually accepted method of sepg. heroine and morphine is based upon the soly. in Et₂O of the free base heroine from an ammoniacal soln., morphine being relatively insol. and remaining in the aq. soln. In practice this method did not prove satisfactory because of the presence of EtOH and the ready soly. of this. Chemically pure CCl₄ proved to be a more satisfactory solvent, the free heroine being readily sol. while morphine is only very slightly sol. Settling of the solvent is rapid owing to its sp. gr. and there is practically no emulsion formed. CCl₄ also dissolves the free bases of dionine (ethyl morphine), peronine (benzoyl morphine), and codeine (methyl morphine).

M. I. W.

Selection and technic of an appropriate method for estimating phenol. JOHN W. FORBING. *J. Am. Pharm. Assoc.* 5, 166-9(1916).—A summary of the several methods and modifications of methods for the estimation of phenol with comments. The choice rests ultimately on 3 factors: accuracy, time and economy. F. outlines a further modification of Sutton's modification of the Koppeschaar method. In practice this modified method was found to give slightly lower results than the U. S. P. modified method for phenol.

M. I. W.

Hydrolysis of some of the common vegetable oils (RUDD) 27.

Methylenetetrahydropapaverine. A. PICTET. U. S., 1,176,597, Mar. 21. Hydro-papaverine is condensed with methylal in acid soln. The product in the form of the free base forms colorless crystals, m. 157-8°, easily sol. in alc. and CHCl₃ and difficultly sol. in ether and cold C₂H₄. The hydrochloride m. 228-30°. The condensation product with acetal m. 148° and that with diethylbenzacetal m. 260-2° (hydrochloride m. 304-6° with decompn.).

Distillation of formic acid. A. BRAUER. U. S., 1,174,663, Mar. 7. A thin layer of a mixt. of Na formate and H₂SO₄ is applied to the surface of a heated drum within a closed reaction chamber and the solid residue is continuously scraped off the drum after distn. of the HCOOH produced.

Acetic acid. N. GRÜNSTEIN. U. S., 1,174,250, Mar. 7. HOAc is made by the reaction of C_2H_2 , H_2O and O at a temp. of $70-90^\circ$ in a soln. formed of HOAc, H_3PO_4 and HgO (or other Hg compd.). C_2H_2 and O are alternately introduced and a 90% or higher yield of 95% HOAc is produced.

Catalytic hydrogenation. C. F. BOEHRINGER & SÖHNE. Brit., 21,948, Nov. 3, 1914. In the hydrogenation of unsatd. substances in the presence of a suboxide of the Ni group as catalyst, the substances are treated when in soln. or suspension in an alc. instead of in H_2O as in the process described in 21,883 C. A. 10, 1081. In examples, dihydroquinine is obtained by treating quinine-HCl in soln. in MeOH or EtOH in the presence of Ni suboxide, and cinnamylcocaine is hydrogenated when in soln. in EtOH in the presence of Ni suboxide.

Acetic anhydride; acetaldehyde. BOSNISCHE ELECTRICITÄTS AKT.-GES. Brit., 23,190, Nov. 27, 1914. Ac_2O is obtained by heating ethylidene diacetate above its b. p., or by heating it with catalysts. The catalysts specified are H_2SO_4 or $HgSO_4$. AcH is obtained as by-product in the above process. Cf. C. A. 10, 666.

Organic acid anhydrides. R. MÜLLER and DEUTSCHE CELLULOID-FABRIK. Aust., 70,783, Dec. 27, 1915. In the manuf. of anhydrides of organic acids, or their mixts. with the corresponding acids, N oxides, together with air or O, or N_2O_5 alone, are conducted over the salts of the corresponding organic acids. Cf. C. A. 9, 3118.

Unsymmetrical arseno compounds. FARBW. v. M. L. & B. Aust., 70,778, Dec. 27, 1915. In a modification of the process of 59,292, organic arsinic acids or arsenoxides, in admixt. with inorganic As compds., are subjected to reduction.

Arsenic antimony compounds. FARBW. v. M. L. & B. Aust., 70,779, Dec. 27, 1915. In a modification of the processes of 59,292 and 70,778 (*supra*), for the production of unsymmetrical arseno compds., As-Sb compds. are obtained by subjecting to reduction an Sb compd. in admixt. with an organic arsinic acid or an arsenoxide. Cf. C. A. 9, 694.

Acetone and alcohol. BAYER & Co. Ger., 286,148, Jan. 25, 1914. See Brit., 14,371 (C. A. 9, 3326).

Alcohols. C. DILL. Fr., 477,812, Oct. 6, 1914. An alkyl halide is made to react with a basic compd. in the presence of a liquid while the entire mass is in intimate admixt., and at an elevated temp., or under increased pressure, or by combining all these factors.

Medicinal, cosmetic, or edible salve-like products. REICHHOLD, FLÜGGER & BOECKING STADLAUER LACKFABRIK. Aust., 70,772, Dec. 27, 1915. Aq. alc. soln. of cellulose hydroacetates or cellulose sulfoacetates are mixed, preferably with heating, with therapeutically active substances, perfumes, sweetening, or taste correctives, which either possess themselves a solvent power for the particular acetylcellulose, or dissolve in indifferent solvents or softening agents, or combine therewith during the process of manuf.

Lactide. CHEM. WERKE v. H. BYK. Aust., 70,776, Dec. 27, 1915. Pure or tech. inactive lactic acid, preheated or not, is heated to temps. above 135° , converting it thereby first into a wholly or partly anhydrous high mol. product, which breaks up when heated to a temp. above 200° , preferably by distn. *in vacuo*, in the presence or absence of a gaseous or liquid vehicle.

Gallic acid from gall-nuts. NITRIFABRIK AKT.-GES. Aust., 70,784, Dec. 27, 1915. Gallic acid is obtained by extn. of fermented gall-nuts, sumac, and the like, with alc., ether, or other suitable solvents. After the fermentation is complete, the mass is dried, preferably at an elevated temp., in order to render the slimy impurities formed during fermentation insol. in the solvent.

Anti-tubercular serum. REICHOLD, FLÜGGER & BORCKING STADLAUER LACK-FABRIK AND H. DOSTAL. *Aust.*, 70,773, Dec. 27, 1915. Tubercle bacilli are subjected to the action of physiological salt soln. with the introduction of a sufficient amt. of O, the resulting new, heretofore unknown coccus-like cultures are injected into animals of various ages, and then the serum is obtained from the blood of these animals in the known manner.

Water-soluble silver glycocholate compound. FARBW. v. M. L. & B. Ger., 284,998, Jan. 30, 1914. NH_3 is allowed to act upon Ag glycocholate.

18. ACIDS, ALKALIES, SALTS AND SUNDRIES.

T. LYNTON BRIGGS.

The introduction of finely divided water into lead chambers. G. SCHUPHAUS. *Metall u. Erz* 12, 504-6(1915).—Introduction of steam into H_2SO_4 lead chambers entails the expense of a boiler plant. Water may be substituted for the steam provided it is introduced as a fog.
CARLE R. HAYWARD.

Potash from kelp. I. F. LAUCKS. *Met. Chem. Eng.* 14, 304-8(1916).—Kelp (*Nereocystis luetkeana*) from Puget Sound is being treated to make its K content available for fertilizing purposes. The kelp is harvested by an app. consisting of submerged reciprocating knives behind which a conveyor is placed to carry the cut kelp aboard a scow. A chopping machine cuts it into short lengths for convenience in unloading. The kelp is conveyed from the scow to water-tight bins having provision for drainage to the dryers, since a large percentage of the water in the kelp squeezes out under its own pressure when piled, and this liquor carries with it a proportional amount of the K. The kelp is shredded in a Williams hammer-type mill during which considerable liquor is also set free before being fed to the direct-heat, rotary dryer. Efficient drying calls for prevention of burning of the material in the dryer since this causes loss of N. The dryer must be equipped with suitable dust collectors since as much as 20% of the weight of product is sometimes collected from the dust chambers. The product of the dryer with such a feed is fine enough so that it requires no further reduction to mix with other fertilizing materials. It is packed in paper-lined sacks and marketed. The K and N are sold on a unit basis. The N in kelp has been shown to be as available as other nitrogenous fertilizing materials, while the high organic matter is valuable in furnishing humus to soils. Pure KCl and K_2SO_4 may be obtained from dry kelp by counter-current leaching. The KCl is sepd. from the NaCl by crystn. The I left in the mother liquors can be obtained by ordinary methods. Algin, the colloid substance found in kelp, shows promise of becoming valuable. Costs and yields are discussed.
E. A. TSCHUDY.

Potash from kelp in southern California. H. L. GLAZE. *Met. Chem. Eng.* 14, 355-7(1916).—A review and discussion of many of the processes being tried in the development of the industry.
F. W. SMITHER.

A method for the utilization of niter-cake. J. GROSSMANN. *J. Soc. Chem. Ind.* 35, 155-6(1916).—Niter-cake showing by test about 30% free H_2SO_4 could be expressed by the formula $5\text{Na}_2\text{SO}_4 + 3\text{H}_2\text{SO}_4$ which corresponds to 70.7% Na_2SO_4 and 29.3% H_2SO_4 . A soln. of niter-cake and CaSO_4 would decompose as follows: $(5\text{Na}_2\text{SO}_4 + 3\text{H}_2\text{SO}_4) + 6\text{CaSO}_4 = 2\text{Na}_2\text{SO}_4 + 6\text{NaHSO}_4 + 6\text{CaSO}_4$; further, $2\text{Na}_2\text{SO}_4 + 6\text{NaHSO}_4 + 6\text{CaO} = 2\text{Na}_2\text{SO}_4 + 6\text{NaOH} + 6\text{CaSO}_4$. The original amt. of CaSO_4 suffices for any number of operations. After sepn. from the CaSO_4 the soln. contains mainly NaOH and Na_2SO_4 . On boiling down, the Na_2SO_4 is fished out, and the final liquor is either used as caustic or further concd. and made into solid caustic soda.

The CaSO_4 produced may be made into pearl hardening. The actual yield from 100 tons of niter-cake was 36 tons of pure Na_2SO_4 and 15 tons of caustic soda. Costs of production are discussed.

E. A. TSCHUDY.

Salt industry and resources of the Philippine Islands. A. J. COX AND T. DAR JUAN. *Philippine J. Sci. (A)* 10, 375-401 (1915).—A detailed account with numerous illustrations, tables, diagrams, etc. The majority of the plants in the Philippine Islands use solar heat, a few direct artificial heat, and none steam heat or grainer methods. (cf. 7th Ann. Rept. U. S. Geol. Survey 505 (1886).) Analyses of the waters used, the soil, and the commercial product are given. Philippine salt contains from a trace to 6.1% CaO and from a trace to 1.9% MgO . *Conclusions:* "The brine should not be transferred to the crystallizing ponds until the salt is ready to crystallize out ($d_{20} 1.205$), since in the evapn. reservoirs large quantities of gypsum and other matter had pptd. before the salt settled out. If there is a proper balance in the plant, in at least the last 2 reservoirs large quantities of undesirable substances will be removed and a purer grade of salt will result. The area occupied by the crystallizing ponds should be as small as possible to accommodate the brine concd. in the evapn. reservoirs, for in that way as much salt is obtained with less labor. When the brine in the crystallizing pond has a $d_{20} 1.275$, it should be drawn off and worked over for the by-products or should be discarded. Expts. show that salt with a purity of 99.63% NaCl may be obtained with these precautions. Efforts should be made to improve the quality of the output and to develop a larger industry in the Philippines." Numerous references to the literature are given.

F. W. SMITHER.

The technical production of hydrogen and its industrial application. H. L. BARNITZ. *Met. Chem. Eng.* 14, 391-5 (1916).—A review.

E. H.

Use of niter cake in the manufacture of ammonium sulfate (COOPER) 21.

Fluosilicic acid. P. A. RACICOT. U. S., 1,175,294, Mar. 14. SiF_4 and HF are brought into a mixing chamber and treated with H_2O .

Potash from alunite. C. F. HAGEDORN. U. S., 1,175,439, Mar. 14. Calcined alunite is heated under pressure with H_2O to effect soln. of the K and the soln. formed is filtered at a temp. of 90° or higher to retain all the dissolved K in soln. during filtration.

Apparatus for digesting bauxite with alkaline solutions. H. HOWARD. U. S., 1,175,147, Mar. 14. The app. consists of a digester capable of withstanding heavy internal pressure and provided with an internal steam coil and stirrer and an external heat-insulating covering.

Precipitating oxides and hydroxides from metal chloride solutions. A. O. BLICKLE. U. S., 1,175,587, Mar. 14. To effect selective recovery of Cu and Zn from chloride

solns., just sufficient Ca(OH)_2 or CaCO_3 is added to the soln. to ppt. a basic salt of Cu and then the ppt. is heated with additional Ca(OH)_2 to convert it into oxide or hydroxide. The residue of Cu compd. is lixiviated to recover Zn or other metals from it, and remove CaCl_2 .

Lead arsenate. L. SHEPHERD. U. S., 1,175,565, Mar. 14. A mixt. of PbS and As_2O_3 is burned with air and a blast of hydrocarbon fuel and the cooled solid product is collected in settling chambers. An app. for carrying out the process is shown, in which an air blower 4 and gas pipe 6 supply a blast flame into which material is fed by a screw from the hopper 1. From the

combustion chamber 7 and flue 9 the products pass through a cooling pipe 12 to settling chambers 13 and bag filters 14 and exhaust gases are discharged through the stack (not shown).

Sodium sulfate; chlorine; sulfuryl chloride. GOLDSMIDT AKT.-GES. Brit., 23,287, Nov. 30, 1914. Na_2SO_4 and Cl are obtained by Hargreaves' process at temps. above 505° and below the m. p. of the salt present at any time. The reaction may be carried out in an inclined rotary furnace on the counter-current principle, powdered salt being employed. The temp. may be regulated by regulating the velocity of the gases or the proportion of O. Cf. 20,604, 1893. By using excess of SO_3 , SO_2Cl_2 is obtained.

Hydrogen sulfide and the sulfides of the alkalis and the alkaline earths. S. KUNSTSEIDENFABRIK A.-G. Ger., 286,947, Nov. 24, 1914. The object of the process is to work S-containing residues of all kinds, *e. g.*, the sepd. S or S-gypsum mixt. from the denitration waste liquors upon treatment with acid, which contains also organic substances, with a view to obtaining H_2S and sulfides or acid sulfides. The S-containing residues, after being mixed with alkalis or alk.-earths, alone or together with reducing organic substances, are heated to dull redness. A part of the S reacts with the H_2O present in the mixt. to form H_2S , while another portion is combined with the alkali, with the formation of sulfites, sulfides, or polysulfides. The latter constitute a very active reducing agent for the sulfates present in the mixt., so that finally, for the complete reduction to CaS , they need be heated for a short time only, supposing sufficient organic substances were present. Due to the alkalis or alk.-earths, not only is sublimation of free S prevented, but also, by the reducing action of the resulting polysulfides on the sulfates, a technical effect, not anticipated, is secured. An especially suitable admixt. for the S-containing residue appears to be the so-called sugar-lime slime, which, in addition to CaCO_3 , shows a high content of organic substances. A mixt. of gas is obtained which consists almost exclusively of H_2S and CO_2 , and, because of the absence of indifferent gases, has proved suitable for the subsequent reaction with CaS or alkalis, or for the manuf. of acid sulfides. *E. g.*, S-gypsum mixt. 100 kg. is mixed intimately with sugar-lime mixt. 100 kg., and heated to dull redness in retorts, in an air-dry condition. The resulting gas mixt. is composed essentially of H_2S and CO_2 . This mixt. is collected in a gas holder over oil, and can be worked up into alkali and alk.-earth acid sulfides. The retort residue is reduced in a reverberatory furnace or lime kiln to CaS which is slimed in H_2O and converted into CaCO_3 and Ca(HS)_2 by the introduction of the retort gases composed of H_2S and CO_2 .

Titanium salts. H. SPENCE, H. WRIGLEY and SPENCE & SONS. Brit., 23,089, Nov. 26, 1914. Ti oxalate in a sol. form, in which the mol. ratio of TiO_2 to C_2O_3 is approx. 1:1, is obtained by treating a Ti alkali sulfate or Ti sulfate with alkali oxalate, or $(\text{HOCO})_2$, or both. The reagents may be intimately mixed in a solid or moist state, or may be heated and dried together.

Alkali sulfates; chlorine; sulfuryl chloride. F. BERGIUS. Brit., 23,288, Nov. 30, 1914. In the production of alkali sulfates and Cl by treating chlorides with SO_2 and air or O, the temp. of the salt mixt. is kept below its m. p., which varies during the process, the lowest point being the eutectic point (about 623°) when about equimol. proportions of chloride and sulfate are present. The chloride is preferably powdered and may be treated in an inclined rotary tube, no external heat being required except to heat the end at which the hot gases enter to about 500° to start the operation. If an excess of SO_2 is used, Cl_2SO_2 is formed. The temp. is regulated by regulating the rate of flow of the gases. Cf. 15,152, 1899.

Sodium carbonate. M. SPAZIER. Fr., 477,964, Mar. 9, 1915. An app. for the manuf. of $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$, comprizing 2 crystg. vats, a reservoir vat situated above these crystg. vats and provided with means for delivering the soln. into one or the other of them, and a dripping table arranged over said crystg. vats and discharging into them. Cf. C. A. 9, 849.

Extracting sea-salt from sea water. LUCIEN-PAUL BASSET. Fr., 477,928, July 8, 1914. The water is fed continuously on to a bed of impermeable soil, in a very thin layer, whereby the evapn. process is rendered intensive.

Potassium salts from feldspar. E. L. ANDERSON. U. S., 1,174,795, Mar. 7. Feldspar is decomposed by heating to $135\text{--}175^\circ$ under a pressure of 50–75 lbs. per sq. in. with a soln. of HF 5% and H_2SO_4 95%. An excess of feldspar is preferable and steam is blown off during the heating to maintain the concn. of the H_2SO_4 . The K is recovered as K_2SO_4 or K alum.

Aluminium sulfate. P. R. HERSMAN. U. S., 1,176,292, Mar. 21. $\text{Al}_2(\text{SO}_4)_3$ is produced from Al skimmings, screenings, slags or other crude material by washing with H_2O , treating the residue with dil. H_2SO_4 to dissolve out most of the Fe, then treating the residue with strong H_2SO_4 to dissolve the Al, neutralizing the excess of acid present by addition of raw material partially freed from Fe and crystg. the $\text{Al}_2(\text{SO}_4)_3$ from soln. after pptn. of any Cu which is present.

Separating thallium and radioactive metals from lead ores, and making a white lead pigment. J. B. HANNAY. U. S., 1,175,146, Mar. 14. Pb ores containing Tl and radioactive metals are volatilized with hot CO and N or other reducing gases free from O and the fume produced is mixed with a large excess of air just after leaving the heating zone. The oxidized fumes are gradually cooled and the deposits formed are successively collected in a series of settling chambers. A pigment of the approximate compn., $3\text{PbSO}_4 \cdot \text{PbO}$, is obtained. The deposits carrying Tl and radioactive materials are again subjected to the same operation to effect concn.

Reducing tungsten compounds. C. BOSCH and A. MITSCH. U. S., 1,175,693, Mar. 14. Pure WO_3 is reduced with H at a temp. of about 600° or slightly higher under a pressure of over 10 atm., preferably 80–150 atm., to obtain a finely divided W suited for use as a catalyst in the synthesis of NH_3 .

Ammonia from its elements. BAYER & Co. Ger., 286,719, Jan. 15, 1914. Addition to 285,698 (C. A. 10, 668). According to the principal patent the decompn. products obtained by heating the alkali and alk.-earth salts of hydroferro- and -ferri-cyanic acids, with exclusion of air, are used as contact bodies. Experience has shown that these products catalyze a mixt. of N and H more effectively, if they have been

produced, at a temp. below 500° , in a current of N and H or of one of these gases, if necessary, under increased pressure. *E. g.*, dehydrated $\text{Ba}_2\text{Fe}(\text{CN})_6$ is heated gradually, under high pressure, in a high pressure app., in a current of a mixt. of N and H. Even at 300° the contact body is formed, with the formation of NH_3 . At 430° , and a pressure of 180 atm., a continuous formation of NH_3 results, with a yield of 17-18% by vol.

Apparatus for producing ammonia from its elements. CENTRALSTELLE FÜR WISSENSCHAFTLICH-TECHNISCHE UNTERSUCHUNGEN G. M. B. H. Ger., 286,666, Feb. 25, 1914. In the synthesis of NH_3 by heating a mixt. of N and H under pressure in the presence of a catalytic agent, in a double-jacketed tubular reaction chamber, the outermost wall is protected from the destructive action of diffusing H by means of the middle wall, of Al, which resists the chem. action and diffusion of the H. A thin-walled Al tube is fitted tightly in a thick-walled Fe pressure tube, and into this Al tube is forced a thin tube of low-C Fe. By turning over the projecting ends of both of the inner tubes and screw-fitting, the gas under pressure is prevented from entering between the tubes. Upon the introduction of pressure, the inner tubes are forced outwards against the outer Fe tube. While, after heating, the innermost tube allows the passage of H, but not that of N by which the Al tube would be attacked, this Al tube prevents the diffusion of H. The outer pressure tube of Fe is completely protected from the injurious action of the H. The outer pressure tubing is made preferably of alloyed steel.

Nitrogen oxides and ammonia from the combustion of a highly concentrated mixture of ammonia gas and air. FARBW. v. M. L. & B. Ger., 286,751, Feb. 20, 1912. An amt. of air is employed such that after oxidation and cooling, there remains, besides N oxides, only pure N, which is converted into NH_3 in the known manner. In the combustion, *e. g.*, of an NH_3 -air mixt. with 10.7% NH_3 , NO is obtained in the furnace, with almost theoretical yield, calcd. to the N of the NH_3 . Upon cooling, this NO is oxidized, as a second step, with the aid of residual O, to N_2O_4 . Upon sufficient cooling the H_2O resulting from the combustion of the NH_3 seps., partly in the form of aq. HNO_3 as a product of reaction with N_2O_4 . The O required for this third oxidation step is taken from a part of the N_2O_4 , with the formation of some NO. In the event of the sepn. of HNO_3 , the NH_3 concn. must be somewhat less in order that, after the production and removal of the aq. HNO_3 and the N_2O_4 , as such or in the form of nitrate and nitrite, the waste gases may be free from NO.

Cyanogen compounds. NITROGEN PRODUCTS CO. Fr., 477,918, Mar. 8, 1915. In the manuf. of compds. of $(\text{CN})_2$ with the aid of N, C, and an alkali or alk.-earth metal or a compd. thereof, under the influence of a molten metallic catalyzer such as Fe, satd. with C, a mass of the material is plunged into the molten catalyzer in such manner as to break up bubbles arising in the bath from gaseous materials which have been introduced, thereby increasing the period of contact with the catalyzer.

Electric furnace for fixing nitrogen. J. E. BUCHER. U. S., 1,174,667, Mar. 7. The furnace is designed for fixing N as CN compds., *e. g.*, forming NaCN by heating a briquetted charge of Fe, C and Na_2CO_3 which serves as elec. resistor in the furnace.

Fixing nitrogen in an electric furnace. J. E. BUCHER. U. S., 1,174,668, Mar. 7. A briquetted mixt. of Fe, C and Na_2CO_3 is heated in a current of N by annular Fe electrodes to form NaCN, the charge itself serving as an elec. resistor. Hot gases are used to preheat the charge.

Fixing nitrogen. J. E. BUCHER. U. S., 1,174,944, Mar. 7. A mixt. of alkali metal vapor and N or NH_3 or producer gas heated to about $800-900^{\circ}$ produced in the chamber 26 is passed through the conduit 6 and allowed to bubble up through a mass

of molten Fe 5 with an overlying mass of graphite 24, heated by electrodes 7 and 10. Graphite is supplied by the screw conveyor 12 and cyanide and CO produced are led off through the pipe 13. Na vapor is formed by electrically heating a mixt. of Na_2CO_3 and coke in the chamber 26. The outer casing of the app. may be made of cast Fe, with a lining formed of powdered hard magnesia brick 50, alundum cement 50 and borax or borax glass 2-3 parts, with an intermediate layer of kieselguhr or MgO . If desired, fuel oil may be supplied through the pipe 36 to furnish C for the reaction and instead of Na vapor unreduced Na_2CO_3 in either liquid or vapor form may be introduced into the molten Fe in mixt. with N to form NaCN . Use of Mn, Ni or Co in the molten catalyst permits operation of the process at lower temps. and may facilitate the process, especially when K compds. are used. If Fe alone is used it is maintained at 1500° in making NaCN .

Fixing nitrogen. H. R. MOODY and S. A. TUCKER. U. S., 1,175,007, Mar. 14. N is supplied through the pipe H and a carbide of Ca, Ba or Li (or a mixt. of carbide-forming materials) is elec. heated in the chamber D by electrodes A, A', one of which may be made tubular to serve also as a conduit for the introduction of N if desired. Compds. containing C and N are formed, e. g., CaCN_2 , $\text{Ca}(\text{CN})_2$, or $\text{Ca}(\text{C}_2\text{N}_2)_2$, with a smaller amt. of nitride. Volatilized compds. are collected in the condenser F and removed at G. Addition of 5% of CaCl_2 to the charge facilitates the reaction.

Hydrogen peroxide. FIRMA HENKEL & CO. Aust., 70,746, Dec. 27, 1915. In the manuf. of H_2O_2 ,

continuously, by electrolysis under increased pressure according to 67,125, the interior wall of the tubular high-pressure vessel is coated with suitable electrode material, and

serves as cathode, while an anode, covered with a suitable diaphragm, is disposed axially within the vessel.

Hydrogen. W. NÄHER and M. NÖDDING. Ger., 286,960, June 13, 1914. Addition to 279,726 (C. A. 9, 1233). The principal process is modified by employing steam superheated to at least 200°, and heating the metals to at least 400°. The production of the reducing gas and the reduction of the metal oxides are effected at a temp. of at least 400°. Coal, charcoal, metallurgical coke, gas coke, soot, or graphite are employed for the manuf. of the reducing gas. In addition to the steam, small amts. of air, CO₂, generator gas, water-gas, or illuminating gas may be conducted through the coal.

Hydrogen. CHEM. FABRIK AKT.-GES. v. MORITZ MILCH & Co. and F. BERGIUS. Ger., 286,961, Nov. 21, 1913. Addition to 254,593 (C. A. 7, 1270). The process is a modification of that specified in the principal patent, wherein metals or lower oxides of metals are brought into reaction with H₂O. An almost quant. yield of H is realized, in a short time, if the H₂O is brought into reaction as steam, and not as liquid, with the metals. The process can be carried out continuously with ease, by allowing the high-pressure steam to flow, periodically, through the container filled with the reactive metal and mounted in or on the pressure bomb, while the exhausted contents of the container are regenerated by reduction by means of gas, or renewed by means of a fresh charge. By following this process the active metal is more effective and the reaction proceeds at a much lower temp. In carrying out the process, the pressure is so chosen that H can be removed, at the prevailing pressure, from the reaction chamber. If, *e. g.*, the H is to be charged into bombs, a reaction pressure of 150-200 atm. is employed. The reaction temp. should not be allowed to exceed 500°, since above this temp. the resistance of the vessel is greatly decreased. The admixt. of elec. conducting salts, such as NaCl, Fe₂Cl₆, or the like, is recommended.

Hydrogen. BADISCHE. Aust., 70,747, Dec. 27, 1915. In the production of H by the catalytically induced reaction between steam and CO, the catalytic agents used are composed of the O compds. of the rare-earth metals, especially of Ce, with the addition of activating substances. Cf C. A. 9, 2803.

Removing lead from zinc compounds. S. E. GOLDSCHMIDT & SOHN and J. ZAWADZKI. Aust., 70,743, Dec. 27, 1915. In the removal of Pb from Zn compds. with the aid of Zn(OAc)₂ solns., the process of 47,525 is modified in that dil. Zn(OAc)₂ solns. are employed, at moderate temps., to ppt. equiv. amts. of ZnO, whereupon the resulting Pb acetate soln. is pptd. with Zn to recover the Zn(OAc)₂.

Contact masses. G. SCHICHT A.-G. Aust., 70,771, Dec. 27, 1915. In the production of nickeliferous contact masses, with the employment of pulverulent carriers, kieselguhr or like porous substances are satd. with Ni(CO)₄, whereupon the carrier is heated to effect the pptn. of the metallic Ni. The nickeliferous powder so obtained is immediately worked up to a paste, with exclusion of air, in the known manner, with oil, or the substance to be hydrogenized, or a soln. thereof.

Spraying and atomizing pulverulent material. A. MAUSER. Ger., 286,637, Feb. 24, 1914. Small amts. of the material (metal, celluloid, lac, resin, glass etc., in stick or rod form) are taken, continuously or periodically, by mechanical means, as by shaving, filing, or turning, and immediately atomized or blown on to the article to be coated, by means of heated or cold compressed gas.

Drying systems. G. D. HARRIS. Brit., 23,291, Nov. 30, 1914. In a drying process, hot air is passed over one surface of a mass of material, and is then reheated to the same or a higher temp. and passed over the other surface. The material may be arranged within compartments, the walls of which form, together with the support of the material, tapering passages which retard the flow of the air.

Concentrating liquids. J. HARRIS and D. H. THOMAS. Brit., 23,414, Dec. 2, 1914. In concd. acid, alk., or neutral liquids or sirups, the liquid, fed through funnels, passes through a series of pipe-like evapg. vessels arranged in cascade. A number of series of pipes are arranged side by side in a flue, so that the pipes form floors, and ports are arranged at alternate ends of each floor for the passage of hot gases between the floors. Asbestos rope or like packing may be laid between the pipes. The pipes are provided with transverse weirs to regulate the height of liquid in them, and with outlets discharging into funnels leading to the inlet of the pipe below. The funnels have upwardly projecting sides to catch splashes. The vapors may be collected in flues formed by side walls. Cf. 7,728, 1912 (C. A. 7, 2999).

Cellulose acetate in gramophone records. A. EICHENGRÜN. U. S., 1,175,728, Mar. 14. The facing layer of records is made of acetyl cellulose mixed with a filler and a softening agent, e. g., dichlorohydrin.

Colloidal graphite. H. KARPLUS. U. S., 1,175,958, Mar. 21. Graphite is peptized by the action of strong oxidizing agents such as $\text{KClO}_4 + \text{HNO}_3$ at a temp. which is regulated by tests and is varied according to the size of granules under treatment to prevent formation of graphitic acid. The reaction products are washed and the highly dispersed portion is sepd. from that less dispersed by elutriation in an aq. soln. of saponin.

Preserving amalgams. J. W. SMITH. U. S., 1,176,176, Mar. 21. Amalgams for use in dental work are cooled and kept in a frozen condition until desired for use and are then heated to render them plastic.

Abrasive. C. C. SHATTUCK. U. S., 1,176,174, Mar. 21. A molded abrasive for sharpening edged tools is formed of pumice stone, dry white lead, Spanish white, Japan drier and turpentine.

19. GLASS AND CERAMICS.

G. E. BARTON, A. V. BLEININGER.

Influence of alumina on the fusibility of glasses. L. SPRINGER. *Keram. Rundschau* 23, 271-2, 280(1915).—Polemical (cf. Singer, C. A. 10, 102). S. states that increase of fusibility of glasses containing a small amt. of Al_2O_3 was due to replacement of SiO_2 by pegmatite. Increase of pegmatite again decreases fusibility of glass. The compn. of the glass used by S. was not the best according to the Tscheuschner formula and addition of Al_2O_3 improved them. Reply. SINGER. Examples are shown of influence of Al_2O_3 in silicate mixts. in lowering fusion point. R. K. HURSH.

The melting of glass. F. M. *Keram. Rundschau* 23, 147-8, 172, 184-5, 202(1915).—Descriptive of general operations in melting of glass. R. K. HURSH.

Permanganate as a substitute for saltpeter in the glass industry. L. SPRINGER. *Keram. Rundschau* 23, 214-5(1915).—At 250° KMnO_4 dissociates to form K_2O , MnO and O. At high temps. Mn_2O_3 and O are formed. To furnish equal amts. of O 3 parts KMnO_4 may replace 2 parts KNO_3 or 1.7 NaNO_3 . As a coloring agent it is $\frac{1}{2}$ as effective as MnO . R. K. HURSH.

Yellow coloring of burnishing silver on the back side. L. SPRINGER. *Keram. Rundschau* 23, 159-60, 177-8, 190, 207-8(1915).—Mixts. of Ag_2CO_3 , metallic, cryst. Ag and amorphous Ag with $\text{Pb}_3(\text{BO}_3)_2$ and Bi_2O_3 as fluxes were burned on 2 kinds of glass at different temps. The burning temp. is most influential in producing yellow discoloration which is more pronounced with increased temp. The nature and quantity of flux has little influence. Results with Ag_2CO_3 and amorphous Ag are much bet-

ter than with metallic, cryst. Ag or Ag containing Cu. Good white color was obtained at cone 022, higher temps. giving slight to deep yellow color. R. K. HURSH.

The future of melting pots. (Optical glass.) ANON. *Brit. Clayworker* 24; *The Brickbuilder* 1916, 46.—Years or generations of aging are required for best results. Careful building required 4 months and drying 4 to 8 months. Heating up the pots is accomplished by wrapping with straw and smoking, followed by gradual heating to redness in 5 days. Invisible cracks from too rapid heating may ruin the pot. The manuf. of optical glass is not in itself remunerative. The famous Jena thermometer glass is sold at an actual loss. Optical glass making should be combined with instrument making to distribute the cost. The real problem is pot manuf. Impurities especially iron compds., dissolve into the glass. Probably materials other than clays must be used, i. e., MgO, silundum, SiC, W, Mo, etc. C. H. KERR.

The use of ceramic raw materials and compounding fine ceramic bodies on the basis of the chemical analysis. JOS. DORFNER. *Sprechsaal* 48, Nos. 24-30 inclusive (1915).—Numerous references are made to literature on the constitution of clays and the rational analysis. D. concludes the rational analysis is inadequate since it does not show the true constitution of clays and bodies, does not give evidence of their refractoriness and does not permit a satisfactory calcn. of the Seger formula. The chem. analysis shows completely the compn. of the body and indicates its pyrometric behavior especially when expressed by means of the Seger formula, from which may be noted the compn. of the flux radical, the ratio of bases to acids and the ratio of refractory to fusible constituents. The limits of compn. in the mol. formula are given for various types of ware. The ratio, base:acid = 1:(1-2) normally. As the acid approaches the lower limit the fire resistance increases, the more it exceeds the upper limit the greater is the tendency to deform and fuse. In the R^oO high K₂O gives low, and high CaO, high maturing temp. Bodies low in K₂O are more plastic with similar materials. High CaO makes a tender faience or stoneware body; high K₂O gives a strong body. The higher the CaO in the body the less the crazing of the glaze on stoneware. The less plastic the clay, the whiter the color of the burned ware and the greater the translucency at maturity. R. K. HURSH.

Crystal glazes. C. KABUS. *Keram. Rundschau* 23, 139-40, 165-6, 178-9, 183-4 (1915).—A crystallizing substance is fritted and added in small fragments to a glaze. On burning, these form crystals in the glassy eutectic. A long period at high temp is desirable. Zn silicates require slow cooling for crystn. TiO₂ requires quick cooling to prevent soln. of the crystals. Addition of NH₄VO₃, TiO₂, MO₃ or WO₃ to the glaze promotes crystn. Formulas for flow glazes and ground glazes are given for several temps. R. K. HURSH.

The subdivision of whiteware glazes into fritted and raw portions and their relation to glaze defects. H. HARKORT. *Keram. Rundschau* 23, 273-5, 285-6, 297-5, 317-8 (1915); see C. A. 10, 260. R. K. HURSH.

Influence of fine grinding on bodies and glazes. C. TOSTMAN AND W. PUKALL. *Keram. Rundschau* 23, 145-6, 153-5 (1915).—Discussion of former article by P. (C. A. 9, 3341). T. states that fineness of 9200 mesh sieve is too great for ceramic bodies and glazes. R. K. HURSH.

A new opacifier for white iron enamels. ANON. *Keram. Rundschau* 23, 221-2 (1915).—Spinel made by heating together MgO and Al₂O₃ or ZnO and Al₂O₃ may be used. By using 5% of these and 0.5 % of a stronger opacifier instead of 10% spine; the opacity is improved. R. K. HURSH.

Refractory products without clay. E. PODSZUS. *Ceramique* 18, 178-80 (1915).—ThO₂, ZrO₂, Al₂O₃, quartz and MgO can be made into a paste by fine grinding and mix-

g with an appropriate agglomerant, as gelatin, gum tragacanth, albumin, lacquer, urnish or collodium. For pure burnt material some easily dissociating salt of the rare element which forms the base can be used, as Th acetate for ThO_2 . Continuous rapn. with a salt of the base renders the base colloidal and it can then be worked as clay. J. C. EVANS.

Classified fusible cones of French manufacture. L. LEFFREVE. *Ceramique* 18, 17-8(1915).—L. gives a table showing the melting points of the cones manufactured by Guérineau and Co. with the corresponding German cones. J. C. EVANS.

Working of clay by the dry way. ANON. *Ceramique* 19, 3-4(1916).—By uschhof's process an extremely fine powder is obtained by grinding the clay in a ball mill and separating by an air separator. This is mixed with a light addition of water, oil or other liquid and converted into clods, triturated and sieved to the required degree. This grainy mass can then be compressed. J. C. EVANS.

Colloidal clay. P. ROHLAND. Stuttgart. *Kolloid-Z.* 17, 145-6(1915).—Polemical H. I. MATTL.

Laboratory porcelain—The requirements of the chemists. ANON. *Ceramique* 18, 30-1(1915). J. C. EVANS.

Photography on porcelain or on glass. ANON. *Ceramique* 19, 4-5(1915).—F. I. Besse and E. P. Rouanet's processes are described. J. C. EVANS.

Screen for excluding intense light. A. H. PFUND. U. S., 1,176,313, Mar. 21. A thin film of Au, Cu, Pt, W or Ni, interposed between layers of clear and colored glass is used to protect the eyes from ultraviolet light and other intense rays.

Burning ceramic ware. H. L. DOHERTY. U. S., 1,175,246-7, Mar. 14. A shaft-film structure and method of firing are specified.

Transfer for printing on pottery, etc. S. LEICHTER. U. S., 1,175,779, Mar. 14. A photographic positive of the desired design is formed on glass or a transparent film, a print is made from the positive on sensitized C tissue, fixed on a cylinder or plate of polished Cu or other metal and after developing the tissue the metal is etched to form an intaglio for printing. The printing is executed in relief on paper coated with dextrin or gum in an ink containing mineral color for transfer to pottery or other materials.

Treating mica. P. G. PALMER and J. J. ROBINSON. Brit., 23,067, Nov. 25, 1914. Sheet mica has applied to it on one or both sides a compn. which, when heated to about 2000° F., forms a vitreous glaze. Any suitable pottery glaze or flux may be used. If in the form of a powder, the substance may be mixed with oil or turpentine, or both, and then applied to the mica. Suitable coloring matter also may be added. The coated sheet mica is applicable for making lantern slides, photographic proofs, plates, or prints, covers for watches and lamps, windows, etc.

20. CEMENT AND OTHER BUILDING MATERIALS.

C. N. WILEY.

Oil and Portland cement. SCHUMANN. *Concrete* 8, 21(1916).—The strength of cement was lowered to about the same extent by the action of petroleum, mineral oil and rape oil, where the cement was hardened a sufficient time either in H_2O or alternately in air and H_2O . The denser the mortar or concrete the better its ability to withstand the action of oils. Rape oil proved to have the most deleterious effect on mortars and concretes. By using a 1:1 mortar, carefully fabricated and hardened

1 yr. under H_2O , the resulting surface is perfectly capable of resisting the destructive effects of oil, even when continually brought in contact with it. Animal and vegetable oils are destructive to cement on account of their property of combining with CaO of the cement to form lime soaps. A dense, impervious surface is necessary whenever an oil is likely to come in contact with mortar or concrete. A. A. KLEIN.

Bamber cement-seasoning process and apparatus. ANON. *Concrete* 8, C. M. S. 23-4(1916).—Seasoning is effected with dry steam which does not come in contact with the cement until it has passed the end wall of the tube mill. The amt. of steam to be used varies with the quality, chem. and physical condition and quantity of the cement passing into the tube mill. This can be fixed after short trials of 12 hrs. With some cements made by the rotary-kiln process, the same results are obtained without the addition of gypsum but where a very slowly setting cement is required immediately upon leaving the mill it is advisable to add 0.5% to 0.75% $CaSO_4$ in the usual manner, keeping up the steam pressure to the normal amt. Too much steam causes condensation and a coating of partially set cement on the sides of the tube mill. With most cements an absorption of less than 1% by the cement is sufficient. With this process it is possible to carry a considerable increase in the lime content when desired and still produce a cement which is sound in the boiling test. A. A. KLEIN.

Concrete flows under sustained load. E. B. SMITH. U. S. Office of Public Roads. *Eng. Record* 73, 329-30(1916).—Curves are given showing continued deformation under const. load in 5 in. $\times$ 8 in. beam of 1:2:4 gravel concrete under 1225 lb. load for 18 days. In time the deformations become const. Two weeks were required for concrete to attain its max. deformation with a fiber stress of 500 lb. under the conditions of this test. Stress values obtained from deformations are rather questionable, being dependent on the time factor. This phenomenon of the flow of concrete may explain abnormal stress conditions which apparently exist in some structures. Concrete roads and pavements subjected constantly to expansion and contraction due to moisture and to temp. changes in many cases do not crack, where they apparently should. Concrete arches may also be largely protected from excessive temp. changes by the flow of the material. A. A. KLEIN.

Requirements for acceptance of concrete aggregates based upon standard test. N. Y. Public Service Commission. *Eng. Record* 73, 47-9(1916).—Tests of fine aggregates consist of (1) detn. of % retained on No. 4 sieve, (2) mechanical analysis of the portion passing No. 4 sieve, (3) detn. of silt by washing on No. 100 sieve, (4) detn. of silt by decantation, (5) compressive strength tests of 2 in. cubes, (6) microscopical examn., (7) wt. per cu. ft., (8) voids, (9) sp. gr., (10) reaction to litmus, (11) quant test of organic matter as indicated by loss on ignition, (12) density in mortar, (13) detn. of insol. SiO_2 . Tables are given showing mechanical grading limits for fine and for coarse aggregates. Complete tests of a coarse aggregate include: (1) mechanical analysis, (2) cleanliness, (3) wt. per cu. ft., (4) voids, (5) sp. gr., (6) crushing strength. A. A. KLEIN.

Slag concrete stronger than broken stone. ANON. Columbia Univ. *Eng. Record* 73, 151(1916).—Compressive strength tests of 8 in. $\times$ 16 in. cylinders of 1:2:4 concrete were made at periods from 1 month to 1 yr. Large aggregate was slag in one case and Palisade trap rock in the other. The strengths in lbs. per sq. in. were as follows:

	1 mo.	3 mos.	6 mos.	12 mos.
Slag concrete.....	2465	3496	3567	4187
Trap-rock concrete.....	1975	2961	3053	3537
% increase in strength.....	24.8	18.0	16.9	18.4

A. A. KLEIN.

Construction methods tested in Du Pont concrete road. C. UPHAM. *Eng. Record* 73, 280(1916).—Experiments to det. most suitable methods and materials to use in preventing transverse cracks by means of steel reinforcement or by the addition of hydrated lime. No standard slab length was adopted, joints being placed only when the mixer stopped for more than 15 min. The max. slab length is 460 ft. The pavement is 14 ft. 7 in. wide and 5 in. thick at the sides on a flat subgrade. Three types of reinforcing were used and up to 10% of hydrated lime. With one exception it appears that as the % reinforcement increases the transverse cracks become fewer. On one section where no lime was used the longest reinforced slab that has not developed a crack is 191 ft. When 10% hydrated lime (by vol.) was used, the longest slab to develop no crack was 210 ft. A slab with no reinforcement or lime developed 2 cracks, breaking the slab into 3 sections 299, 118, and 126 ft. long. In 2 slabs where 10% lime was used, no cracks developed, the length of these slabs being 336 and 210 ft. On another section the longest slab without lime showing no cracks was 187 ft.; with 5% lime 245 ft.; and with 10% lime 294 ft. While the data are not sufficient to warrant definite conclusions, they do indicate the advantage of the use of lime.

A. A. KLEIN.

Beach shells as concrete aggregate. A. M. SMITH. *Concrete* 8, 137(1916).—Compression tests were made on 1:1.6:2:6 concrete, using clean, fresh shells that would pass through a 1 in. mesh for coarse aggregates and both white surface and yellow sub-sand for fine aggregate. Crushing-strength tests on 4.78 in. cubes gave results varying from 1,100 to 1,320 lbs. per sq. in.

A. A. KLEIN.

Does alkali disintegrate concrete? ANON. *Eng. Record* 73, 316(1916).—Preliminary conclusions of the disintegrating effect of alkali waters and soils on concrete by the U. S. Reclamation Service engineers are as follows: The principal salts causing disintegration are sulfates, $MgSO_4$ and Na_2SO_4 . The former is thought to be more active. Leaner mixts. of concrete are more easily disintegrated than the richer; more scientifically proportioned mixts. give better results. Alkali-proof cements have not behaved any better than straight portland cement, nor have sand cements.

A. A. KLEIN.

Tests on road materials. R. G. BATSON. *Report National Physical Lab.* 1914-5, 104-13.—Report on tests to det. relative capacity of road stones to resist attrition and impact.

A. A. KLEIN.

Mortar bed for wood blocks. C. H. TRESDALE, H. S. LOUD AND F. CHERRINGTON. *Eng. Record* 73, 154(1916).—Committee of Am. Wood Preservers' Assoc. recommends a 1:4 mortar with just enough H_2O for proper setting as a bed for wood block paving instead of a sand cushion. This bed should be $\frac{1}{2}$ to 1 in. thick.

A. A. KLEIN.

The preservation of wood. G. DE LA PRAILLE. *Rev. gén. chim.* 19, 1-16(1916).—The article is a review and discussion of the methods used in preserving woods. More is to follow.

L. H. CHERNOFF.

Oil specification for creosoted wood block. HERMANN VON SCHRENK. St. Louis. *Proc. Am. Soc. Municipal Improvements* 1915, 178-209.—The preservative for wood paving blocks should be a pure coal-tar compd., but may be either straight creosote or a creosote-tar mixt. Watergas-tar products are considered unsatisfactory. Exceedingly strict specifications are not justified, for excellent results have been obtained with a wide variety of coal-tar oils. The method of treatment is more important than the properties of the oil. It is impossible to get thorough penetration in every block but it is necessary thoroughly to penetrate the sapwood and get as good penetration as possible in the heartwood. Data are given on the conditions found in a number of wood-block pavements, and the character of the oil used.

Geo. M. HUNT.

Some experiences in creosoted wood-block paving. ELLIS R. DUTTON. Minneapolis. *Proc. Am. Soc. Municipal Improvements* 1915, 167-77.—Creosote-tar mixts are satisfactory for wood-block treatment. Sixteen lbs. per cu. ft. is about the right absorption. Southern yellow pine is the best wood for the purpose. G. M. H.

Wood-block pavements with reference to economic and efficient wood preservatives. W. J. HOWARD. New York. *Proc. Am. Soc. Municipal Improvements* 1915, 238-44.—Preservative for wood block should be a straight distillate, containing no added tar or pitch. It should contain at least 10% naphthalene and 15% anthracene oil. Other requirements are suggested. GEO. M. HUNT.

Report of Sub-Committee on Wood-Block Paving Specifications. *Proc. Am. Soc. Municipal Improvements* 1915, 456-70.—A specification proposed by three members of the committee, covering timber, preservative, methods of analysis, and methods of laying the blocks is given, and four other specifications for preservative, suggested by others than committee members. GEO. M. HUNT.

The proper oil for treating creosoted wood blocks for paving. P. C. REILLY. Republic Creosoting Co., Indianapolis. *Proc. Am. Soc. Municipal Improvements* 1915, 210-37.—The addition of coal tar to creosote is an adulteration; tar-creosote mixts. are not suitable for the treatment of paving blocks. After discussing the faults of a number of oil specifications and the qualities of a variety of oils, R. proposes the following specification for improved creosote oil: It shall consist wholly of a distillate from coal tar, d_{40} not less than 1.12 nor more than 1.14; distillate up to 250° not over 1%, to 315° not over 15%, to 355° not over 40%; residue above 355° must be soft and waxy at 25° and have a d_{40} not less than 1.17; a drop heated on white filter paper shall be of yellowish amber color by transmitted light; 25 g. of the oil in an open vessel 2.5 in. diam., 0.75 in. deep, kept at 49° shall not evap. more than 5% in 72 hours; d_{40} of the fraction 400 to 420° not less than 1.12; neither of the fractions 315° to 380° and 380° to 420° shall show a sulfonation residue of over 2%. GEO. M. HUNT.

New penetration needle for testing bituminous materials (REKKE) 22.

Asphalt mixture for making pavements. R. WALLBAUM. U. S., 1,176,006, Mar. 21. A dust-like filler such as limestone is moistened and mixed with an aq. emulsion of asphalt and dried while constantly stirred. The product is then heated and compressed.

Plastic compositions. H. J. GUISE and W. G. PERRY. Brit., 23,345, Dec. 1. 1914. A MgO cement compn. is made by mixing together preferably 55 parts of burnt magnesite, 15 parts of burnt and ground China clay, 15 parts of quartz, 10 parts of asbestos, and 5 parts of wood meal, the dry powder being mixed first with $MgCl_2$ soln. of 16-36° Bé., and then with paraffin oil. One gal. of $MgCl_2$ is used to one pint of paraffin oil. The cement may be colored by adding aniline or other sol. dye to the H_2O . Compns. containing cork, powdered glass, slag, crushed sea-shells, and SiC may be made by adding these materials respectively to the dry mix. Before molding, the molds may be coated with a mixt. of 1 lb. of Russian tallow and 1 qt. of paraffin oil to prevent adhesion; or when using the compn. as an adhesive cement, the surface to be joined may be coated with a liquid consisting of 1 part each of $CaSO_4$ and calcined borax, 6 parts of kieselguhr, 12 parts of calcined magnesite, and 50 parts of $MgCl_2$ soln. of 25° Bé. The compn. may be employed for paving floors, decks, etc., for switch boards, partitions, elec. insulators, slabs, table tops, etc., and for assembling porcelain insulators with metal parts, also for uniting porcelain, stone, metals, wood, glass, and leather.

Artificial stone. J. SKLAREK. Aust., 70,775, Dec. 27, 1915. The initial material,

peat cut during the wet season, is allowed to freeze with its natural H_2O content, and then, after complete drying, it is mixed with the inorganic binders.

Seasoning timber. J. J. OWEN. Brit., 23,411, Dec. 2, 1914. In a process of seasoning timber in closed chambers by subjecting it to the action of distillates or gaseous products of wood or other vegetable matter, coal, coke, etc., the steam is conducted to a chamber containing the timber, by a pipe which may pass through a stove to superheat the steam, which, after enveloping the timber, escapes by suitable pipes. The timber is then dried by steam-heated pipes, and afterwards submitted to the action of the distillates or gaseous products, which are produced in the stove and led to the chamber by a pipe, and after enveloping the timber escape by other pipes.

J. D. PENNOCK.

The application of surface combustion. J. H. LEDERBOER. *Proc. Australasian Inst. Mining Eng.* 1915, 39-58.—A review of Bone's work with drawings of boiler furnace settings.

H. L. OLIN.

Graphic studies of ultimate analyses of coals. OLIVER C. RALSTON. *Bur. Mines, Tech. Paper* 93, 37 pp. (1915).—R. plots the results of 10,000 ultimate analyses of coals of different types, calcd. to moisture, ash-, N-, and S-free basis, by a system of tri-linear coördinates so that $C + H + O = 100\%$. On this ternary diagram fuels classified as anthracite, semianthracite, semibituminous, bituminous and sub-bituminous coal and lignite and peat fall into definite fields that overlap to only a small extent making a narrow band across the diagram with only one distinct bend. The relationship between calorific value and the ultimate analysis is shown by isocalorific lines which are parallel to each other, are almost straight, and cut the band diagonally. Similarly, isovolatil lines run diagonally across the dot curve but make an angle of about 45° with the others. Moisture detns. made with varying humidity of the drying air are inaccurate, and curves of equal moisture content plotted from available data, are of little value. Many coals high in S are also high in H and volatile matter but no rule can be formulated without further investigation.

H. L. OLIN.

Determination of toluene, application of method to benzene and xylene. H. W. JAMES. *J. Soc. Chem. Ind.* 35, 236-40 (1916); *J. Gas Lighting* 133, 531-3 (1916).—The method consists of dividing the total distillate into 2 parts, Part I being a mixt. of C_6H_6 and $C_6H_5CH_3$, and Part II a mixt. of $C_6H_5CH_3$ and xylenes. These parts in turn are very accurately fractionated under carefully regulated conditions. The sample, distg. up to 140° , is sepd. into 6 distillates, each of a few degrees range. The 4 intermediate portions are redistd. up to 110.6° and the fractions brought together in the first and last receivers, these boiling, resp., below and above 110.6° . Fraction I is now further distd. and the distillate measured at frequent specified intervals. The percentage distillate at these temps. is calcd., and comparison with tables shows the $C_6H_5CH_3$ content. Fraction II is treated similarly, and the % $C_6H_5CH_3$ added to that found in Fraction I, is the total in the sample. A correction for paraffin hydrocarbons may be made by taking the sp. gr. of Fraction II and allowing 1% for every 0.002 variation from 0.867 at 15.5° . For naphthas containing not less than 30% $C_6H_5CH_3$, the error in this method is less than 1%. For low $C_6H_5CH_3$ samples about 40% of pure $C_6H_5CH_3$ may be added and corrected for in the calcn. Detailed instructions for carrying out the method when starting with a tar sample, and also its application to the detn. of C_6H_6 and xylene are given.

R. H. SAWENS.

Estimation of benzole in coal gas, ANON. *J. Gas Lighting* 133, 460.—A review of French methods.

R. H. SAWENS.

Naphthalene. H. SIMMONDS. *Gas World* 64, 220-1(1916); *J. Gas Lighting* 133, 470-4(1916).—Of various means tried for preventing stoppage by naphthalene, the most successful method used was by atomizing a light naphtha (sp. gr. 0.770 with compressed air, at a pressure of 25 lbs. per sq. in. into the 24 in. main at outlet of governors, the oil and air passing through $\frac{1}{4}$ in. supply pipes, the oil being regulated by means of a spindle and dial and the air by the size of the hole in the spray nozzle. It was regulated to deliver 200 cu. ft. of air and 1 gal. of oil for an hr. There was no appreciable difference in illuminating power, but a slight increase in calorific value. Total cost was equal to 0.51 d. per ton coal carbonized or 0.042 d. per 1000 cu. ft. of gas. The amt. of oil atomized equals 0.176 gal. per ton of coal carbonized. Drawing and photograph of atomizer are shown. M. L. TROWBRIDGE.

Estimation of benzole in lighting gas. ANON. *Gas World* 64, 224(1916).—A method consisting of the use of freezing mixts. in Dewar vacuum flasks by passing 25-30 l. of gas through the refrigerating tube at the rate of 10 l. per hr. M. L. T.

Burning and distilling water-gas tar. C. OTTEN, JR. *Am. Gas Light J.* 104, 149-51(1916).—O. describes the plant at Haverhill, and gives the results recorded.

M. L. TROWBRIDGE.

Carbonization of pitch. T. DUXBURY. *J. Gas Lighting* 133, 482-3(1916).—Under similar conditions ordinary coals, and coals with the addition of 5 and 10% of pitch were carbonized. Best results were obtained by using 5% pitch. In carbonizing this mixt. for each ton of coal there was an increase of 310 cu. ft. of gas, 75 lbs. of coke and 3.5 gals. of tar. The calorific value of the gas was increased from 581 to 594 B. t. u. and the c. p. from 16.20 to 16.73. The coke was improved, the heats being increased. With pitch the results were similar. Analyses of the tars showed increases in $C_{10}H_8$, $C_6H_5CH_3$, and pitch, while the moisture was somewhat lower in samples resulting from the coal and pitch carbonization. R. H. SAWENS.

Use of niter cake in manufacture of sulfate of ammonia. G. S. COOPER. *Chem. Trade J.* 58, 235(1916); *J. Gas Lighting* 133, 523-4(1916).—The article is largely a reprint of the Eng. Govt. recommendation to use niter cake in place of H_2SO_4 . A solu. of equal parts by wt. of H_2O and niter cake is mixed with chamber H_2SO_4 in the ratio of 2 to 3, and heated to about 200° F. The acidity is maintained at about 6% by frequent titrations. The first crop is largely Na_2SO_4 but a salt of the right compn. is soon obtained by maintaining proper conditions in the bath. In a cool bath Na_2SO_4 seps. Nitrates in the cake are to be avoided. The salt yields 18 to 20% NH_3 on a wet basis. On a dry basis the av. analysis is: $(NH_4)_2SO_4$ 83.2, Na_2SO_4 15.4, free acid 1.4%. The process saves from 15 to 25% H_2SO_4 . R. H. SAWENS.

"T. R. Sprayoil" apparatus for prevention of naphthalene troubles. W. THOMSON, R. H. RUTHVEN AND W. J. CARPENTER. *J. Gas Lighting* 133, 139(1916); *Gas World* 64, 51-2(1916).—A solvent oil is atomized by pressure into the mains and the lighter portion carried along with the gas. The remainder returns to the receiver and again goes through the spraying app. taking up in all about 4% $C_{10}H_8$. Deposits already in the mains may be cleared out by blowing some of the unsatd. residual oil through the mains or introducing it at high points. R. H. SAWENS.

Gas mantle metals. I. Cerium. J. SCOTT. *J. Gas Lighting* 133, 79-80(1916).—Metallic Ce and the theory of its use in the Welsbach mantle are described. S. studied the metal and its salts under the microscope. First he noted that when scratched with a knife it very readily gave off white-hot globular particles which burst after leaving the original piece of metal. The latter oxidizes very readily when exposed to the air into exceptionally fine flour-like particles which have the same incandescent property as the metal. The formation of salts with mineral acids showed the nitrate to be amorphous or semi-crystalline and very deliquescent. The sulfate first found was a

fine crystalline powder developing later into bold rhombic crystals. With HCl a film developed into polygonal pattern with resetted figuring in the meshes, the crusted portion being opaque and perforated. These eventually deliquesced to a mass of boat-shaped, scaly and notched flakes in peculiar arrangement. R. H. SAWENS.

War problems in coking industry. G. S. COOPER. *J. Gas Lighting* 133, 475-9 (1916).—The following problems are discussed: (1) elimination of As from H_2SO_4 by means of pptn. with H_2S from the NH_3 stills, (2) substitution of niter cake for H_2SO_4 in the production of $(\text{NH}_4)_2\text{SO}_4$, (3) various problems in preparing NH_3 products for the market, (4) disposal of pitch, (5) benzole recovery. R. H. SAWENS.

New penetration needle for testing bituminous materials (REEVE) 22.

Fuel. N. SULZBERGER. U. S., 1,174,199, Mar. 7. Finely divided coal is mixed with spent fuller's earth which has been used in treating oils or fats and the mixt. is molded into briquets.

Fuel for internal-combustion engines. R. WOOD. Fr., 278,070, Mar. 17, 1915. The product consists of a mixt. of alc. and ether in proportions varying between 70-30° by wt. of alc., and 30-70° by wt. of ether, preferably in equal parts by wt. NH_3 may be added in small amt. E. g., 95% alc., 54.3% by wt., ether 45% by wt., NH_3 0.5% by wt., and As 0.2% by wt.

Oxy-acetylene and like lamps. G. F. JAUBERT. Brit., 23,443, Dec. 2, 1914. A rare earth compd. for incandescent lighting by means of an oxy-acetylene or like burner contains a small proportion of an alk. polysilicate, such as ground glass, acting as a flux, so that the surface exposed to the flame hardens quickly and may be regenerated by the application of a little of the compd. in a dry or slightly moist condition. The compd. may consist of ThO_2 92 parts, CeO_2 2 parts, MgO 2 parts, CaO 1 part, and ground glass 3 parts, and may be used in a receptacle for carborundum, alundum, etc., with a circular groove near the mouth.

Surface combustion. A. ADAM. Fr., 477,958, July 9, 1914. The mixt. of the combustible gas and the gas supporting combustion is prevented until these gases have passed into the porous diaphragm.

Apparatus for carbonizing peat. O. A. FORD and J. C. LONG. U. S., 1,175,944, Mar. 21. The peat is passed through a long drum in which it is heated by hot gases and after drying is ground out of contact with the air.

Gas producer. G. M. S. TAIT. U. S., 1,175,191, Mar. 14.

Gas producer. B. VERSEN. U. S., 1,175,844-5, Mar. 14. Cf. C. A. 9, 2585.

Gas producer. J. O. CARREY. U. S., 1,176,429, Mar. 21.

Coal-gas apparatus. C. S. CHRISMAN. U. S., 1,176,432, Mar. 21. Vertical coal-gas retorts are heated from an adjacent gas producer and combustion chamber fed with coke from one of the retorts. The gas pressure at the base of this retort is adjusted so that producer gas is excluded from the retort when the coke is passed to the producer and coke is withdrawn from the bottom of the other retorts not communicating with the producer.

Retorts for making coal gas. H. A. CARPENTER. U. S., 1,174,390, Mar. 7.

Retort for the distillation, carbonization, and like heat treatment of coal. C. W. TOZER. Fr., 278,040, Mar. 15, 1915. The retort comprizes a series of chambers arranged around a central axis, all these chambers being of practically the same size, as specified in Brit., 20,158, Sep. 3, 1909. The particular construction permits of the

ter than with metallic, cryst. Ag or Ag containing Cu. Good white color was obtained at cone 022, higher temps. giving slight to deep yellow color. R. K. HURSH.

The future of melting pots. (Optical glass.) ANON. *Brit. Clayworker* 24; *The Brickbuilder* 1916, 46.—Years or generations of aging are required for best results. Careful building required 4 months and drying 4 to 8 months. Heating up the pots is accomplished by wrapping with straw and smoking, followed by gradual heating to redness in 5 days. Invisible cracks from too rapid heating may ruin the pot. The manuf. of optical glass is not in itself remunerative. The famous Jena thermometer glass is sold at an actual loss. Optical glass making should be combined with instrument making to distribute the cost. The real problem is pot manuf. Impurities, especially iron compds., dissolve into the glass. Probably materials other than clays must be used, i. e., MgO, silundum, SiC, W, Mo, etc. C. H. KERR.

The use of ceramic raw materials and compounding fine ceramic bodies on the basis of the chemical analysis. JOS. DORFNER. *Sprechsaal* 48, Nos. 24-50 inclusive (1915).—Numerous references are made to literature on the constitution of clays and the rational analysis. D. concludes the rational analysis is inadequate since it does not show the true constitution of clays and bodies, does not give evidence of their refractoriness and does not permit a satisfactory calcn. of the Seger formula. The chem. analysis shows completely the compn. of the body and indicates its pyrometric behavior especially when expressed by means of the Seger formula, from which may be noted the compn. of the flux radical, the ratio of bases to acids and the ratio of refractory to fusible constituents. The limits of compn. in the mol. formula are given for various types of ware. The ratio, base:acid = 1:(1-2) normally. As the acid approaches the lower limit the fire resistance increases, the more it exceeds the upper limit the greater is the tendency to deform and fuse. In the R'O high K₂O gives low, and high CaO, high maturing temp. Bodies low in K₂O are more plastic with similar materials. High CaO makes a tender faience or stoneware body; high K₂O gives a strong body. The higher the CaO in the body the less the crazing of the glaze on stoneware. The less plastic the clay, the whiter the color of the burned ware and the greater the translucency at maturity. R. K. HURSH.

Crystal glazes. C. KABUS. *Keram. Rundschau* 23, 139-40, 165-6, 178-9, 183-4 (1915).—A crystallizing substance is fritted and added in small fragments to a glaze. On burning, these form crystals in the glassy eutectic. A long period at high temp. is desirable. Zn silicates require slow cooling for crystn. TiO₂ requires quick cooling to prevent soln. of the crystals. Addition of NH₄VO₃, TiO₂, MO₃ or WO₃ to the glaze promotes crystn. Formulas for flow glazes and ground glazes are given for several temps. R. K. HURSH.

The subdivision of whiteware glazes into fritted and raw portions and their relation to glaze defects. H. HARKORT. *Keram. Rundschau* 23, 273-5, 285-6, 297-8, 317-8 (1915); see C. A. 10, 260. R. K. HURSH.

Influence of fine grinding on bodies and glazes. C. TOSTMAN AND W. PUKALL. *Keram. Rundschau* 23, 145-6, 153-5 (1915).—Discussion of former article by P. (C. A. 9, 3341). T. states that fineness of 9200 mesh sieve is too great for ceramic bodies and glazes. R. K. HURSH.

A new opacifier for white iron enamels. ANON. *Keram. Rundschau* 23, 221-2 (1915).—Spinel made by heating together MgO and Al₂O₃ or ZnO and Al₂O₃ may be used. By using 5% of these and 0.5% of a stronger opacifier instead of 10% spinel the opacity is improved. R. K. HURSH.

Refractory products without clay. E. PODZUS. *Ceramique* 18, 178-80 (1915).—ThO₂, ZrO₂, Al₂O₃, quartz and MgO can be made into a paste by fine grinding and mix-

ing with an appropriate agglomerant, as gelatin, gum tragacanth, albumin, lacquer, varnish or collodion. For pure burnt material some easily dissociating salt of the same element which forms the base can be used, as Th acetate for ThO_2 . Continuous evapn. with a salt of the base renders the base colloidal and it can then be worked as a clay.

J. C. EVANS.

Classified fusible cones of French manufacture. L. LEFEVRE. *Ceramique* 18, 177-8(1915).—L. gives a table showing the melting points of the cones manufactured by Guérineau and Co. with the corresponding German cones.

J. C. EVANS.

Working of clay by the dry way. AXON. *Ceramique* 19, 3-4 1916.—By Tuschhof's process an extremely fine powder is obtained by grinding the clay in a ball mill and separating by an air separator. This is mixed with a light addition of water, oil or other liquid and converted into clods, triturated and sieved to the required degree. This grainy mass can then be compressed.

Photography on porcelain or on glass. AXON. *Ceramique* 19, 4-5 1915.—M. I. Besse and E. P. Rouanet's processes are described.

J. C. EVANS.

Screen for excluding intense light. A. H. PFUND. U. S., 1,176,313, Mar. 21. A thin film of Au, Cu, Pt, W or Ni interposed between layers of clear and colored glass is used to protect the eyes from ultraviolet light and other intense rays.

Burning ceramic ware. H. L. DOHERTY. U. S., 1,175,246-7, Mar. 14. A shaft-kiln structure and method of firing are specified.

Transfer for printing on pottery, etc. S. LEICESTER. U. S., 1,175,770, Mar. 14. A photographic positive of the desired design is formed on glass or a transparent film, a print is made from the positive on sensitized C tissue, fixed on a cylinder or plate of burnished Cu or other metal and after developing the tissue the metal is etched to form an intaglio for printing. The printing is executed in relief on paper coated with dextrin or gum in an ink containing mineral color for transfer to pottery or other materials.

Treating mica. P. G. PALMER and J. J. ROBINSON. Brit., 23,067, Nov. 25, 1914. Sheet mica has applied to it on one or both sides a compn. which, when heated to about 2000° F., forms a vitreous glaze. Any suitable pottery glaze or flux may be used. If in the form of a powder, the substance may be mixed with oil or turpentine, or both, and then applied to the mica. Suitable coloring matter also may be added. The coated sheet mica is applicable for making lantern slides, photographic proofs, plates, or prints, covers for watches and lamps, windows, etc.

20. CEMENT AND OTHER BUILDING MATERIALS.

C. N. WILEY.

Oil and Portland cement. SCHUMANN. *Concrete* 8, 21 1916.—The strength of cement was lowered to about the same extent by the action of petroleum, mineral oil and rape oil, where the cement was hardened a sufficient time either in H_2O or alternately in air and H_2O . The denser the mortar or concrete the better its ability to withstand the action of oils. Rape oil proved to have the most deleterious effect on mortars and concretes. By using a 1:1 mortar, carefully fabricated and hardened

Temp.	Pressure.	Feed (gal. per hr.).	% oil recovered.	C ₆ H ₆ and C ₇ H ₈ (in recovered oil).	
600°	250 lbs. per sq. in.	22	35	8.6	5.7
650		22	31	10.3	9.0
700		22	26	16.1	10.0
750		22	21	25.7	9.5
800		22	17	6.5	5.3
650		18	27	8.5	8.9
650		28	25	13.6	12.4
700		11	21	18.7	13.6
700		14	25	23.2	12.0
700		18	22	20.0	12.7
700		24	25	10.8	10.0
700		27	29	5.2	7.5

Multiplying the % of C₆H₆ and C₇H₈ in the recovered oil by the % of recovered oil, the % of C₆H₆ and C₇H₈ in the original oil is obtained. In obtaining the results given in the following table a distillate oil was used, the same tube being employed:

Temp.	Pressure (lbs. per sq. in.).	Feed (gal. per hr.).	% oil recovered.	C ₆ H ₆ and C ₇ H ₈ (in recovered oil).	
600°	150	14	36.3	7.0	10.8
625	175	14	30.0	14.3	13.9
700	200	14	20.0	23.6	13.0
650	200	15	24.0	20.4	16.4
625	200	14	30.0	14.7	15.3
600	200	14	30.0	8.0	11.4
550	200	14	55.0	0.0	4.2
700	250	15	22.5	22.4	12.9
650	250	15	23.5	20.2	15.7
600	250	15	31.2	9.1	12.8

When the dimensions of the tube were made 8 in. in diam. and 14 ft. long and the pressure was kept constant at 250 lbs. the results were:

Temp.	Feed (gal. per hr.).	% oil recovered.	C ₆ H ₆ and C ₇ H ₈ (in recovered oil).	
625°	32	25	20.23	12.57
650	24	14	31.17	15.51
650	31	23.2	18.45	13.17
675	29	16	27.47	12.88

The av. results were less favorable than in the 10 ft. tube with same diam. The longer exposure to heat caused by the 4 ft. increase in length seems to have caused the condensation of the low-boiling aromatics into hydrocarbons of great mol. wt., as well as an increase in the formation of gases and carbon. In a tube 8 in. in diam. and 7 ft. long, the % recovery of oil was higher for the same temps., pressures, and rates of feed than with either the 8-in. by 10-ft. or the 8-in. by 14-ft. tubes. The yields of C₆H₆ and C₇H₈

were, however, less, indicating that the 7-ft. tube was too short for commercial purposes. It was finally decided that for a tube 8 in. in diam. a length of 10 ft. was the most efficient. The increase in the diam. of the reaction tubes gave consistently better results. In the latest benzene-toluene plant, tubes of 10³/₄ in. internal diam. are being successfully employed. With the increased diams., rates of feed exceeding 60 gals. per hr. have been readily obtained with satisfactory yields of aromatics. A series of six furnaces containing 10 tubes each was constructed, the individual tubes being 8 in. in diam. and 14 ft. in length. Some of the results obtained in the operation of these furnaces are tabulated below:

Temp.	Pressure (lbs. per sq. in.).	Feed (gal. per hr.).	% oil recovered.	C ₆ H ₆ and C ₇ H ₈ (in recovered oil).	
Varied from 600 to 800°.	100	18	38	7.9	5.3
	175	26	37	10.8	8.9
	250	30 (200 gal. used)	33	15.1	7.6
	250	30 (580 gal. used)	30	20.0	7.7
	250	30 (1,070 gal. used)	27	25.2	8.9
	250	30 (1,529 gal. used)	26	24.2	8.8

The % of C formation was large due to the semi-asphaltic nature of the Oklahoma crude oil. A distillate from Pennsylvania crude, boiling between 250 and 400° was used in the later tests. It was found desirable to remove the gasoline fraction, and residuum before putting any crude oil through the cracking process. At first 1 to 1¹/₂ lbs. of C per gal. of oil was formed, when the crude oil was employed. When the distillate was used, ¹/₄ to ¹/₂ lb. C per gal. was obtained. This amt. had been reduced to ¹/₁₀ lb. per gal. In order to reduce the mechanical difficulties with regard to the long stirring rods, 10 tube furnaces were built, in which the individual tubes were 8 in. in diam. and 11¹/₂ ft. long. In these expts. the rate of feed and pressure were materially reduced. The results were as follows:

Temp.	Pressure.	Feed (gal. used).	% oil recovered.	C ₆ H ₆ and C ₇ H ₈ (in recovered oil).	
600 to 800°.	150 lbs. per sq. in.	242	29.2	11.7	11.7
		590	28.0	12.1	13.9
		1,130	28.0	12.5	13.6
		1,878	25.6	11.9	13.9
		2,753	34.5	9.7	11.2

The percentages of C₆H₆ and C₇H₈ are not the max. ones, since they are based on the amt. of aromatic hydrocarbons in the distn. fraction up to 175°. The residue from the 175° cut is suitable for re-running through the furnace. At least twice the amt. of C₆H₆ and C₇H₈ would be obtained if this residual oil were put through the cracking process again. No recovery of the aromatics carried mechanically in the uncondensed gases was made. It was demonstrated that the single-tube furnace was much superior to the 10-tube furnace, because of a greater uniformity of heating conditions. The mechanical equipment as finally decided upon at the Aetna Explosives Co.'s plant consisted of a series of 10 cracking tubes, 8 in. by 11¹/₂ ft. long, fitted at the upper end with feed line for each furnace, and at the lower end with a C pot and vapor line. A stirring rod fitted with chains spirally arranged served to keep the walls of the tube free from C. The C deposit falls through the tar neck into the C pot. The vapors pass through the vapor line into the condensers, and the condensate is collected in a primary and secondary separator. The condensations were not very efficient, this accounting for the low yields of aromatics. A gas scrubber and a condensing area of 3 ft. per 1000 cu. ft. of gas are recommended. The gas scrubber may be similar to the benzene scrubbing towers

in by-product coke oven plants. The tubes are heated by gas burners, the consumption per tube being 300 cu. ft. per hr. The number of gas burners for each furnace was 22. The expts. indicated that the vapor-phase cracking process is not limited to a particular kind of oil. Certain oils formed by the destructive distn. of coal were converted readily to C_4H_8 and C_7H_8 . The production of gasoline by this process was tested in a 6-in. by 9-ft. tube, and in an 8-in. by 10-ft. tube. The oil used was a distillate boiling between 250° and 350° . The temps. in the furnace ranged from 550° to 650° , the pressure was const. at 250 lbs. per sq. in., and the rates of feed ranged from 13 to 26 gals. per hr. The results in the 6-in. by 9-ft. tube are tabulated below.

Temp.	Pressure.	Feed.	% oil recovered.	% gasoline in recovered oil.
550°	250 lbs. per sq. in.	17	54	35
550		26	92	14
600		17	79	36
600		23	78	25
625		22	76	27
650	250 lbs. per sq. in.	19	69	31
650		21	79	24
650		25	86	20

The sp. gr. of the recovered oil varied from 0.800 to 0.828. The sp. gr. of the gasoline in the recovered oil ranged from 0.772 to 0.723. Both the % of recovered oil and the % of gasoline are low due to inefficient condensation. The tests with 8-in. by 10-ft. tube showed an av. % of gasoline of 18.8, as against 19.5 in the smaller tube. In comparison with the benzene-toluene process, the gasoline process is simple in character. The order of hydrocarbon reactions described below is substantiated as a result of many tests. [Heavy petroleum hydrocarbons $\rightleftharpoons$ light petroleum hydrocarbons (satd. and unsatd.)] $\rightleftharpoons$ cymene, etc. $\rightleftharpoons$ xylene $\rightleftharpoons$ toluene $\rightleftharpoons$ benzene $\rightleftharpoons$ naphthalene, diphenyl, etc. $\rightleftharpoons$ anthracene, etc. $\rightleftharpoons$ carbon and gas. The duration of the gasoline reaction is less than half that required for the C_6H_6 and C_7H_8 reaction; hence the capacity is more than doubled. The results indicate the success of both the gasoline and the C_6H_6 - C_7H_8 processes. A bibliography of 364 references with a brief abstract in each case is appended (compiled by M. S. Howard). O. E. BRANSKY.

Petroleum and the war. A. GUTSELIN. *Mat. grasses* 9, 4451-54(1916).—G. considers the situation in Rumania, Galicia, and Alsace, and gives statistics.

E. J. KELLEY.

New penetration needle for testing bituminous materials. C. S. REEVE AND F. B. PRITCHARD. U. S. Dept. Agric. *J. Agr. Res.* 5, 1121-6(1916).—It is pointed out that there is no definite standard for penetration needles. No. 2 needles manufd. by R. J. Roberts are recommended by the Amer. Soc. for Testing Materials but these vary considerably and have to be selected. A needle is designed for standard so that it can be easily duplicated. It is made from 2 in. length of 0.041 in. annealed steel drill rod by placing the rod in a lathe and with a fine file turning the end to a point with $\frac{1}{4}$ in. taper, then tempering, grinding to fine point and polishing. The finished needle must be perfectly smooth, have a straight taper $\frac{1}{4}$ in. long and be exactly 0.04 in. above the taper.

The chemistry of pine oil. M. FOSCH. *Mat. grasses* 8, 4355-8(1915).—F. gives a description of the methods of extn. and the properties of the oil. E. J. KELLEY.

Acetic anhydride. J. T. HEWITT AND C. H. LUMSDEN. *J. Soc. Chem. Ind.* 35, 210-3(1916).—A comparison of various methods of manuf. of Ac_2O . The authors conclude that the use of the chlorides of P or S with $AcONa$ is the most suitable method.

Attempts at forming Al_2O_3 by decompn. of Fe and Al acetates by means of heat were unsuccessful. H. W. DAUDT.

Lubricants for metals (BLAIR) 9.

Cracking heavy hydrocarbons. W. A. HALL. U. S., 1,175,909, Mar. 14. See Brit., 17,121 (C. A. 9, 375).

Cracking hydrocarbon oils. W. A. HALL. U. S., 1,175,910, Mar. 14. Crude petroleum oil or a distillate heavier than gasoline is fed by a pump 1 through a coil 2 of 1-1.5 in. pipe in the furnace 3 and coils 4 heated to $540-600^\circ$ by burners 5. Cracked vapors and gases produced are led through the pipe 7 through a valve 8 (which is regulated to maintain about 75 lbs. pressure per sq. in. in the coil 4) to a dephlegmator 9 (filled with short pieces of pipe) in which the temp. and pressure are allowed to fall to 325° and 10 lbs., resp., where C separates. Heavy oil deposited is drawn off at 12. Uncondensed products are passed to the second dephlegmator 14 which has a temp. of about 180° and the condensate there sep'd. is used in a subsequent run in the coil 4. Gases and vapors passing through the separator 16 are compressed to 100-125 lbs. in the compressor 17 which effects an endothermic reaction between the constituents of the mixt. and on passing the products of this reaction through coolers 19 and 20 a yellowish light distillate collects in the tank 21. When this is mixed with fullers' earth and distd. or clarified with H_2SO_4 a water-white petroleum spirit is obtained, which is suitable for use in automobile engines.

Apparatus for distilling hydrocarbons from absorbing oils. F. PÜNING. U. S. 1,176,094, Mar. 21. The app. is arranged for continuous distn. of light hydrocarbons such as C_4H_{10} from heavier absorbing oil and is arranged so that different portions of the distg. system may be cut out for repairs without discontinuing the distn.

Removing coke deposits from oil stills. L. MOONEY. U. S., 1,174,888, Mar. 7. A chain is placed in the bottom of the still and raised to break up any cokey deposits that form above it.

Apparatus for making gas from liquid hydrocarbons. W. C. DAYTON. U. S. 1,174,970, Mar. 14.

Making gas from oil. The app. is arranged for continuous distn. of light hydrocarbons such as C_4H_{10} from heavier absorbing oil and is arranged so that different portions of the distg. system may be cut out for repairs without discontinuing the distn.

W. C. DAYTON. U. S., 1,174,971, Mar. 14. Air and oil regulates their relative amts. and pressures and subjected

STANDARD OIL CO. FR., 477,829, Feb. 27, 1915. The object of the app. is to obtain a low-boiling product from petroleum or from the

residual liquids from the distn. of petroleum. The liquid under treatment is kept in forced and rapid circulation through coils of small diam. which are heated to a temp. which cracks the liquid, circulating between the supply tank and the coils. The resulting vapors are collected and condensed, being maintained at a pressure of 3-7 atm. and at a temp. of 340-450°.

Purifying unsaturated hydrocarbons. F. E. MATTHEWS and E. H. STRANGE. Fr., 477,983, Mar. 11, 1915. See Brit., 6,897 (C. A. 9, 2466).

Purifying mineral oils. A. M. MCAFEE. Brit., 22,922, Nov. 23, 1914. High-boiling mineral oils are purified and freed from unsatd. hydrocarbons by heating them with AlCl_3 or the like at high temps. until a portion has been converted into low-boiling hydrocarbons, which distil off. This residual oil may be distd. in the presence of alkali, and may be air-blown to dry it, and is treated with AlCl_3 at 150° F. for at least 24 hrs. The treated oil is cooled, sepd. from the chloride sludge, treated with H_2SO_4 , washed with H_2O and alkali, and filtered through fuller's earth. The chloride sludge may be used for the treatment of further quantities of oil until a granular coky mass is obtained. The oil after treatment with sludge is treated with fresh AlCl_3 . The process is particularly applicable to lubricating and medical oils. Cf. C. A. 9, 860.

Motor fuel. G. E. HEYL and T. T. BAKER. Brit., 23,014, Nov. 24, 1914. A fuel for internal-combustion engines consists of gasoline, paraffin oil, or other usual spirit mixed with the 170-230° distillate of coal or analogous tar, after this distillate has been freed from acids, bases, and naphthalene by alkali, acid, and cooling, and has been distd. once or twice to a temp. approaching 230°, so long as the distillate is light colored.

Combustible hydrocarbon gas. THE NATIONAL OIL-GAS BURNER CO. Fr., 477,970, Mar. 9, 1915. Volatile hydrocarbons are vaporized, and these vapors are mixed with steam at a temp. which must not be below the temp. of decompn. of steam in the presence of hydrocarbon vapors, and, before burning, mixing the gaseous mixt. thus produced with the non-volatile residue of the hydrocarbon and an amt. of air sufficient for complete combustion.

Aluminium chloride. A. M. MCAFEE. Brit., 22,923, Nov. 23, 1914. AlCl_3 is recovered from residues obtained in processes involving the treatment of petroleum or other oils or fats with AlCl_3 for any purpose, by removing the oil, carbonizing the remaining organic matter, and then treating the hot material with Cl, gaseous HCl , or other gas containing Cl, whereupon AlCl_3 volatilizes and is collected. The oil may be removed by extg. with a solvent such as gasoline, but is preferably removed by heating until the oil becomes sufficiently liquid to be drawn or sucked off. Any suitable app. may be employed, and the process may be effected continuously. Cf. C. A. 9, 2309.

Cracking and refining oils. A. M. MCAFEE. Brit., 22,924, Nov. 23, 1914. In heating mineral oils in the presence of AlCl_3 or Al and Cl for the production of gasoline, burning oils, and other low-boiling hydrocarbons, the operation is stopped while a substantial proportion of the oil, say 30-50%, remains in the still, and the reagent is sepd. from the cooled residual oil, which is found to be free from unsatd. hydrocarbons and asphaltic constituents. The crude oil is first distd. to remove the low-boiling hydrocarbons and H_2O , and is then heated in the presence of AlCl_3 at 470-600° F. The vapors are cooled to 350° F., and the heavier compds. thus condensed are returned to the still, the remaining vapors, consisting of gasoline, etc., being condensed separately. When the evolution of vapors slackens, i. e., after about 36-48 hrs., the residual oil is cooled and treated with H_2SO_4 or steam to remove the AlCl_3 , and is further purified, as by filtration through fuller's earth. The residual oils vary in nature with the crude oils under treatment, and may be worked up into lubricating oils, fuel oils, vaseline, and paraffin wax. Oils containing S and N are freed from these elements. Coky granules containing

the reagent are formed in the still, and may be treated for the recovery of the AlCl_3 by the method described in 22,923, 1914 (*supra*).

Alcohol-soluble asphalt-like products. CHEM. FABRIK FLÖRSHEIM DR. H. NOERDLINGER. Ger., 286,630, July 17, 1914. Wood tar or wood-tar oil is treated with concd. H_2SO_4 , the resulting H_2O -sol. substances are removed, and from the remaining residue the oily portions are removed if necessary, by treatment with steam or air or by extn. with solvents. *E. g.*, heavy wood-tar oil 100 kg. is stirred up slowly with 66° Bé. H_2SO_4 50 kg. and the mixt. is heated, with stirring, for 8–10 hrs. to 90–100°. The mass is then allowed to flow into H_2O , wherein it is boiled until color is no longer extd. The tarry residue is then freed in a suitable manner, if necessary, from the oily portions, by treating it, *e. g.*, with ordinary or superheated steam, whereupon a strongly phenolic oil distils over, and the asphalt-like substances, solid after cooling, remain in the retort. The removal of the oily portions can be effected by treatment of the tarry residue with air, or by extn. with alkalis and subsequent treatment with benzene or turpentine oil. The resulting solid residue is practically insol. in alc., and is claimed to be very suitable for the manuf. of black spirit-asphalt varnish, of black polishes, especially for darkening spirit varnishes and other spirituous solns. for the manuf. of leather blacking and leather preserving preps. and the like, as a black spirit dye, for use as impregnating and insulating agents, and for many other purposes. These varnishes give surfaces which are not attacked by alkalis, acids, benzene, or lubricating oils. The alc. solns. of these asphalt-like products possess also therapeutic value.

Mixture of salts of the lower fatty acids. J. EDERER. Aust., 70,777, Dec. 27, 1915. Macerated wood is treated with lime water or other alk. solns. at the ordinary temp. or with gentle warming to hasten the reaction, and from the resulting lyes the salts or acids are recovered in the known manner.

Wood distillation. H. M. ANGLE and F. J. ROOT. U. S., 1,174,537, Mar. 7. "Hogged" and shredded pine or other wood is compressed into blocks (not more than 8 in. in diameter) and destructively distd. in tubular retorts which are almost filled by the blocks, after preliminary distn. with steam to recover turpentine.

23. CELLULOSE AND PAPER.

A. D. LITTLE.

Rapid method of detecting lead chromate in papers used for wrapping eatables. J. WOLFF. *Paper Makers' Monthly J.* 54, 7(1916).—Moisten a small square strip of paper with 90% alc., and pour off the excess. A few drops of HNO_3 spread over the surface turns the paper green, due to the production of chromium sesquioxide, aldehyde being evolved. The treated paper is washed with 10–15 cc. of H_2O and tested with 10% soln. of KI. Pb, if present, will give a ppt. of PbI_2 . This method is also applicable to papers colored green by PbCrO_4 and Prussian blue. The evolution of aldehyde detected by its odor, proves the presence of Cr; Pb is tested for as above, and Prussian blue by the usual method.

E. J. KELLEY.

Chemical control of the Kraft process. OTTO KRESS. *Paper* 17, No. 24, 30–2 (1916).—A method is given for complete volumetric analysis of sulfate white liquor involving (a) detn. of total alkali by titration with 0.5 *N* acid using methyl orange, (b) of soda as $\text{NaOH} + \text{Na}_2\text{S}$ by similar titration after pptn. with hot BaCl_2 and calcn. from (a), (c) of $\text{Na}_2\text{S} + \text{Na}_2\text{S}_2\text{O}_3 + \text{Na}_2\text{SO}_3$ by I titration and (d) of $\text{Na}_2\text{S}_2\text{O}_3 + \text{Na}_2\text{SO}_3$ by titration with I and with 0.1 *N* NaOH after conversion of the sulfites to bisulfites by treatment with alk. ZnCl_2 and neutralization with H_2SO_4 . Methods for detn. of total alkali, free alkali and Na_2S in black liquor and rapid methods for mill control of

white liquor are also given. This forms the report of the Committee on sulfate pulp of the Tech. Assoc. of the Pulp & Paper Industry. V. NUNEZ.

Some methods for the study of beating. A. B. GREEN. *Paper 17*, No. 24, 21-8 (1916).—A modified Schopper-Riegel tester is described for measuring the slowness or ratio of drainage of pulp from the beater at various stages. A sheet-forming app. which provides for uniformity in d. of stock, distribution on the wire and suction is also described, as well as a folding tester, which consists essentially of two hard plane surfaces set at an angle, from the apex of which the test strip of paper extends, being held between by surfaces at known pressure by a spring. Two rollers, so arranged that their axes are always parallel, are held against the planes at known pressure by a spring. These oscillate across the apex and fold the paper until break occurs. By the use of these apps. valuable information on the progress of beating may be obtained. V. N.

Standardization of ground-wood processes. D. L. BELLINGER. *Paper 17*, No. 24, 34(1916).—A number of points in ground-wood practice are brought forward which require standardization or elucidation. These include barking methods, dimensions of lap pulp, particulars as to basalt lava stone, proper depth to submerge the grinder stone, proper temp. for grinding, best grinding methods in hot weather, proper place to discharge water in the grinder pit. V. NUNEZ.

Substitutes for sulfur and pyrites in the sulfite pulp industry. FRANK. *Papier-Ztg.* 41, 2(1916).—Several possible sources are discussed of S to replace the imported S and pyrites which have become very expensive in Germany. The mineral kieserite, $\text{MgSO}_4 \cdot \text{H}_2\text{O}$, readily yields SO_2 on calcining with C but an adequate supply of this mineral is uncertain owing to its use in potash fertilizers. Nor is NaHSO_4 , a dependable source of SO_2 . Prepn. of SO_2 from CaS obtained by reduction of gypsum or anhydrite is possible according to the following equations: $\text{CaS} + \text{MgCl}_2 + \text{H}_2\text{O} = \text{CaCl}_2 + \text{MgO} + \text{H}_2\text{S}$ and $\text{H}_2\text{S} + 3\text{O} = \text{SO}_2 + \text{H}_2\text{O}$. The MgCl_2 may be recovered as follows: $\text{MgO} + \text{CaCl}_2 + \text{CO}_2 = \text{CaCO}_3 + \text{MgCl}_2$. A complicated plant is necessary for this process, however, and only the largest sulfite mills could undertake it independently. Recovery of S in the form of CaSO_3 by treatment of waste sulfite liquor with lime requires but simple equipment and seems promising. About 40% of the S originally present in the cooking liquor can be recovered by this means. V. NUNEZ.

Waste sulfite liquor, ground wood pulp and cellulose as nutrient in fish ponds. HOFER. *Allgemeinen Fischerei Ztg.* No. 20 and 21(1915); *Papier-Ztg.* 41, 1(1916).—Waste sulfite liquor containing no free SO_2 , wood pulp and cellulose which contain sugars or yield sugars on fermentation have been found beneficial to fish life and growth and to the growth of plankton upon which the fish feed. V. NUNEZ.

Substitutes for rosin. FERENCZI. *Papier-Ztg.* 41, 103-4(1916).—Scarcity of rosin in Germany at present makes the use of substitutes necessary. The tar size of Heuser is recommended for dark papers. Glue can be made to serve as an engine size. Starch prepn. are of some value. The claims that talc has sizing properties are considered erroneous. Hard sizing of print papers is unnecessary and very soft sizing of these sorts is urged. V. NUNEZ.

Use of talc in sulfite tissue paper manufacture. PAUL EBBINGHAUS. *Papier-Fabr.* 4, 59(1916).—Addition of talc in the beater has been found of great advantage when making tissue papers in preventing rosin spots and in effecting saving in the use of dyes. V. NUNEZ.

Zacaton as paper-making material. CHARLES J. BRAND AND JASON L. MERRILL. U. S. Dept. Agr., *Bull.* 309, 27 pp.—Zacaton (*Epicampes macroura*) is an unusually hardy, heavy cropping, perennial grass of profuse growth in Mexico and Central America. The roots are used in the manuf. of brushes. The tops form a possible source

pulp. Cooked by the soda process the grass yields 43% air-dry pulp based on the t. of the air-dry grass. Bleach consumption is around 12%. The pulp is soft, bulky and short fibered and could probably be used in about the same manner as soda poplar pulp. It works up into excellent machine-finish book paper. It would appear possible to grow zacaton as a crop in the U. S. V. NUNEZ.

Sulfite pulp from poplar. JAS. BEVERIDGE. *Pulp Paper Mag. Can.* 14, 30(1916).—By the sulfite process poplar (*Populus alba*) yields 59.34% unbleached pulp equiv. to 1352 lbs. bone dry pulp per cord. Willow (*Salix caprea*) yields 55.65% pulp. The yield from poplar is about 14% higher than by the soda process. V. NUNEZ.

The saw palmetto, a neglected fiber plant of the south. C. D. MELL. *Paper Trade J.* 62, No. 7, 181-2(1916).—Attention is directed to the leaf of the saw palmetto as a possible raw material for pulp. V. NUNEZ.

Manufacture of "photo" papers. ANON. *Papier-Fabr. Papermaker and Brit. Paper Trade J.* 50, 60(1916).—Special precautions must be taken to avoid and eliminate iron. The stock of the best paper is all rag. Ash should not exceed 4%. The papers should be hard sized except when intended for pigment printing. Uniform appearance and look through is important. Breaking length averages 2400 in. and stretch 2.4%. Dilation on moistening should be small. Premature yellowing may be traced to use of spoiled animal size, inferior stock, or the action of Fe in combination with resinic acids. V. NUNEZ.

The mineral pigments used in papermaking. H. A. BROMLEY. *Papermaker and Brit. Paper Trade J.* 50, 55-60(1916).—Nature and methods of analysis of the more common pigments. V. NUNEZ.

Colored tissue paper for artificial flowers. ANON. *Papier-Fabr.* 14, 104-6(1916).—Description of manuf. V. NUNEZ.

Barking drums and their operation. HERBERT GUETTLER. *Paper* 17, No. 24, 36-40(1916). V. NUNEZ.

Adsorption of acids by cellulose (LEIGHTON) 2. Utilization of sulfite liquor for washing purposes (LÖFFL.) 27.

Cellulose. C. HARNIST. *Fr.*, 477,895, July 6, 1914. Crude cellulose is treated in one operation, successively or alternately, with NH_4OH or other sol. alkali or alkali carbonate, on the one hand, and with SO_2 on the other hand. Compressed or liquefied NH_3 and SO_2 are used.

Cellulose in ethers insoluble in chloroform. H. DREYFUS. *Fr.*, 478,023, Nov. 11, 1914. In a modification of the process of 432,046, July 5, 1911, and additions 14,783, Sept. 13, 1911, 16,316, Aug. 5, 1912, and 16,494, Sept. 16, 1912, for the manuf., on a large scale, of cellulose ethers insol. in CHCl_3 , and for obtaining always the highest possible viscosity, or a desired viscosity, the cellulose is treated with H_2SO_4 , as a condensing agent, and in the presence of a diluent such as glacial HOAc , and placed in an acetylizing mixt. which has been previously cooled, i. e., the temp. is kept below $5-15^\circ$, preferably below 5° , as required, with removal of the heat developed during the reaction, and then the temp. is allowed to rise successively to 15, 20 and 25° , and finally even to about $30-35^\circ$. After the max. temp. has been reached, cooling is continued until it falls to about $25-30^\circ$.

Air-drying wood cellulose. R. GAMILLSCHEG. *Aust.*, 70,799, Dec. 27, 1915. The wood cellulose obtained from the wet portion is dried by allowing a warm current of air from below, and a lateral current of cold air, to act simultaneously on the wood cellulose sheets as they are moved forward.

Acetylcellulose plastic composition. F. MEYER. U. S., 1,175,791, Mar. 14. Acetylcellulose is mixed with a solvent and with sufficient non-solvent such as petroleum to inspissate the soln. before pptg. the acetylcellulose and coloring matter is mixed with the thickened soln.

Filaments from cellulose solutions. L. P. WILSON. U. S., 1,175,857, Mar. 14. Tubular threads are formed from viscose solns. or other solns. of cellulose derivs. by forcing the soln. out from an annular orifice, around a core or thread formed either of natural textile fiber or artificial silk, into a pptg. bath.

Electrical insulation from sulfite liquor. W. K. FREEMAN. U. S., 1,175,424, Mar. 14. Waste sulfite liquor after concn. and treatment with NaCl and BaCl₂ is dried with the ppt. still mixed with it and the dried product is mixed with MgO, MgC, powdered glass and a small amt. of a hard gum or resin.

Separating constituents of waste sulfite liquor. W. K. FREEMAN. U. S., 1,175,425, Mar. 14. Conc'd. waste sulfite liquor is agitated with HCl while hot and after boiling and cooling is treated with NH₄OH to ppt. various constituents and leave a soln., from which the cellulosic derivs. may subsequently be recovered, for use in making brush backs, buttons, insulators, etc.

Treating waste sulfite liquor. W. K. FREEMAN. U. S., 1,175,423, Mar. 14. Waste sulfite liquor from wood-pulp mills is heated and evapd. to conc. it, treated with NaCl to assist in coagulating it and then treated with BaCl₂ to ppt. Ca and S compounds and prepare the liquor for use as a source of cellulosic compds. for use in the manufacture of billiard balls or other molded articles.

Cement from waste sulfite liquor. W. K. FREEMAN. U. S., 1,175,425, Mar. 14. Waste sulfite liquor is treated with NaCl and BaCl₂ and the remaining liquor after sepn. of the ppt. is evaporated to dryness and pulverized. 100 parts of this powder is mixed with gum camphor 4, MgO 100 and MgCl₂ 50 parts, with or without SiO₂ or kaolin forming a dry cement which is made ready for use by the addition of H₂O. The mixt. may be used for certain purposes as a substitute for celluloid, bone or ivory.

Cement from waste sulfite liquor. W. K. FREEMAN. U. S., 1,175,426, Mar. 14. Usual ingredients of oxychloride cement are mixed with disintegrated wood or other fillers and with the pulverized residue produced by treating waste sulfite liquor with NaCl and BaCl₂ or other precipitants and evapg. without sepn. of the ppt.

Molding oxychloride-waste sulfite liquor cement. W. K. FREEMAN. U. S., 1,175,427, Mar. 14. Disintegrated wood, corn stalks or other fibrous material is mixed with MgO and with the powdered residue produced by treating waste sulfite liquor with NaCl and BaCl₂ and evapg. without sepn. of the ppt. formed, a soln. of MgCl₂ is added and the plastic mixt. is molded between hot surfaces to expel excess moisture. U. S., 1,175,428 specifies a shoe last made of a similar composition.

Sizing for paper stock. J. A. DE CEW. U. S., 1,174,697, Mar. 7. A H₂O-proofing sizing for mixing with paper stock in a beating engine is formed by permanently emulsifying rosin 50-85 and wool wax, carnauba wax or mineral wax 15-50%.

Waterproofing paper tubes. H. C. PRITHAM. U. S., 1,174,279, Mar. 7. Paper tubes for making cartridge shells are H₂O-proofed by treating them with a soln. of Chinese wood oil 3% in paraffin 97% and heating sufficiently to gelatinize the Chinese wood oil.

Apparatus for recovering pulp from waste printed paper. J. J. WEAVER, P. M. H. L. COLLIER and J. M. EGMOND. U. S., 1,175,854, Mar. 14.

Removing ink from waste paper. J. WELSH. U. S., 1,175,853, Mar. 14. Pulp from waste printed paper made wholly or in part from mechanical wood pulp is recovered by pulping and treating with waste liquor from sulfite or alkali pulp manufacture, draining and washing with fresh H₂O.

Removing metallic particles and other foreign matter from paper pulp. A. J. JEWELL and R. J. MARX. Fr., 477,995, Mar. 12, 1915. Magnetic and other impurities are removed with the aid of an electromagnetic separator, the electromagnets being disposed in a pocket of the plate which conducts the pulp to the paper machine.

Paper fiber or pulp. S. MILNE. Fr., 478,063, Mar. 17, 1915. Suitable raw material is digested in one or more digesters, then it is passed through a pressing and washing machine, again washing or filtering it, then passing all or a part of the filtered material through a refining machine, and again filtering.

Ground wood for paper manufacture. F. FRIEDSAM. Aust., 70,781, Dec. 27, 1915. Mineral filling material (kaolin, talc, blanc fixe, or the like) is added to the wood flour during its prepn. on the grinding stone.

24. EXPLOSIVES AND EXPLOSIONS.

C. E. MUNROE.

Action of explosion gases produced by projectiles. Z. ges. Schiess-Sprengstoffw. 11, 57-8(1916).—The depressing and poisoning action of the gases produced by the explosion of military explosives is discussed. O. L. THOMAS.

Primers for explosives containing liquid air. H. ASSEL. Z. ges. Schiess-Sprengstoffw. 11, 58-9(1916).—The use of primers for igniting explosives charged with liquid air has not been very successful. The momentary heat action of both the ordinary primer and of the Pt wire bridge is insufficient because of the low temp. A bridge igniter composed of explosive metal combinations surrounding a Pt wire bridge may be used. O. L. THOMAS.

Experiments at Commentry on the ignition of coal dust. M. J. TAFFANEL. Z. ges. Schiess-Sprengstoffw. 10, 263-7, 283-6(1915).—A plan of the experimental mine is given. Sixteen experiments performed under varied conditions have given valuable results on the influence of arrangement of the galleries and the spreading of the coal dust explosion. The results are compared with those obtained at Liévin on dust mixts. They have proved the effectiveness of safety zones, the weakening action of bends on the explosion and the usefulness of a new kind of explosion barrier. O. L. T.

The crystalline form of α -trinitrotoluene (ARTINI) 10. Wood flour (KRESSMANN) 18. Determination of toluene (JAMES) 21.

Explosive. A. E. CHARBONNEAUX. U. S., 1,174,546, Mar. 7. Picric acid 4, nitronaphthalene 2, NaNO_3 10 and PbO_2 1 part are used in an explosive for shells. Nitrated petroleum or nitrated turpentine may be substituted for nitronaphthalene to form an explosive for rifles.

Priming charge for explosives. W. H. BUELL. U. S., 1,174,669, Mar. 7. Priming charges are formed of Pb azide 6, nitrocellulose or a nitro-compd. 11 and Na or K azide 3 parts. On ignition, the Na or K azide leaves an alk. residue which prevents injurious action on the gun. A primer may also be formed of KClO_3 30, Sb sulfide 35 and NaN_3 35 parts. When nitrocellulose is used, the sensitiveness of the mixt. is increased by use of amyl acetate or other solvent. Cf. C. A. 10, 970.

Nitrotoluenes. R. A. CRAIG, R. ROBERTSON, R. C. FARMER and G. ROTTER. Brit., 23,181, Nov. 27, 1914. The nitrotoluenes contained in the waste acids from the production of trinitrotoluene are extd. by washing the acids with toluene or a nitrated toluene of a lower degree of nitration than the products to be extd.; if the process is carried out at a suitable temp., the toluene or nitrotoluene used for the extn. undergoes

nitration in the process; fresh HNO_3 may be added to the waste acids for this purpose. When toluene or toluene nitrated below the stage of mononitrotoluene is used as the extg. agent, emulsification of the mixt. is prevented either by adding fresh HNO_3 in amt. sufficient to yield at least mononitrotoluene, or by dilg. the acids with H_2O to a suitable degree before the toluene is added.

25. DYES AND TEXTILE CHEMISTRY.

L. A. OLNEY.

Dyeing in the last quarter of 1914 and the first quarter of 1915. E. K. HALL. *Farber-Ztg.* 26, 169-79(1915).—A review of the literature, including patents.

W. F. F.

Dye shortage in the U. S. A. K. PIETRUSKY. *Chem. Ind.* 39, 1-7(1916).—A review and discussion of development in the U. S.

F. W. SMITHER.

Manufacture of aniline oil. ANON. *India Rubber World* 53, 167(1916).—A general description including diagrams.

E. J. KELLEY.

Testing aniline oil and salt. LOUIS J. MATOS. *Dyestuffs* 18, 94-6(1915); *Textile World Record* 49, No. 5, 115-6(1915).—Aniline oil for hosiery dyeing and for padding and printing cotton goods should b. 182° , 90% distg. at this temp., d_{15} 1.027 and the oil should show no indications of PhNO_2 or hydrocarbons. Grading is done by distn. Aniline oil for black-dyeing should distil as follows for 100 cc.: below 180° 5 cc., $180-5^\circ$ 92 cc. and $185-90^\circ$ 3 cc. For oil of d. 1.027, 90 cc. should have distd. at $182-5^\circ$. Oil having higher d. is likely to contain toluidine or unchanged PhNO_2 , and should be rejected. If 10 cc. is dissolved in 10 cc. HCl and the mixt. dild. to 100 cc., the presence of PhNO_2 , etc., is indicated by turbidity. Aniline salt of satisfactory grade should be in the form of large crystals since small powdery crystals indicate that the sample was prepd. from an oil high in toluidine. The test for free acid in the salt is important. Five drops of crystal violet soln., 1 to 1000, is recommended as indicator comparing the sample with a sample of known purity. Color of aniline oil is unimportant, while discolored aniline salt should be rejected.

W. F. FARAGHER.

Relations between constitution and color of dyestuffs. J. PICCARD. *Bull. soc. vaud.* 50, 311-33(1915); *Beiblätter Ann. Physik* 39, 674; cf. *C. A.* 7, 2939, 2940.—For yellow of the second order, P. obtained *meri*-tetraphenyldiphenquinonediimine, which with its 12 benzene rings, gives the greatest depth of color yet obtained. L. W. R.

The properties of wool and a new chemical method for detecting damaged wool. KLAUS VON ALLWÖRDEN. *Z. angew. Chem.* 29, I, 77-8(1916).—Between the external plate-cells (scales) and the fiber cells (body of the fiber) there is a substance which the author names elasticum. The characteristics of the fiber are largely detd. by this substance. If all of this substance is removed, the fibers are no longer capable of being felted or finished properly and are brittle and weak. Elasticum, which is sol. in alkalis, is a carbohydrate, the osazone of which may be prepd. readily. In 8 l. of 2% NaOH there is suspended 500 g. factory-scoured wool, previously rinsed with warm distd. H_2O . After standing for 24 hrs. at a temp. of not more than 25° , practically all of the elasticum will have dissolved, together with some albuminous substances. Since the former is dialyzable, it may be sepd. from the mixt. The soln. of elasticum thus obtained is acidified with AcOH and concd. to 200 cc. AcONa and PhNHNH_2 are then added, and the mixt. is heated in boiling H_2O . Microscopic needles sep. after $1\frac{1}{2}$ -1 hr. The imperfectly purified osazone m. 188° . The reduction of Fehling soln. by elasticum is effected only after sepn. of albumin, a fact which explains previous failures to detect it. Its reducing action accounts for the reducing properties of wool. The con-

tent of elasticum detn. the value of wool, and mfg. processes should be designed to conserve it. The fiber-cells proper are more easily attacked by acids than the plate-cells and elasticum, which is insol. in acids, is able to protect mechanically the underlying fiber. This fact is of importance in carbonizing and acid-dyeing. Gravimetric detn. of elasticum should give an indication of the properties of the fibers. Optical methods, osazone detn. or Cu reduction are suggested, but none has been worked out. Cl water is a valuable reagent to show the presence of elasticum. The plate cells are not easily attacked by Cl while the fiber-cells and elasticum react readily. The swelling caused by the reaction of the latter forms globular enlargements on the fibers, the plate cells being distended. The wool fiber is placed upon a slide and covered with a few drops of H_2O . An equal vol. of Cl water is then added. The fiber should be viewed under a microscope, at a magnification of about 200. Dynamometric tests are little affected by removal of elasticum, while the wearing qualities of the fabric are greatly impaired. This conclusion was proved by an examn. of a number of uniforms which had been unsatisfactory in service. Damage developing during acid-dyeing is often the fault of the scouring rather than the dyeing. Bottoming in an alk. vat followed by topping with acid dyes is objectionable. Spots are often formed as a result of the reducing action of elasticum.

W. F. FARAGHER.

Recovering caustic from mercerizing washings. H. AUSTIN. *Textile World J.* 51, No. 17, 39(1916).—The equipment furnished by Ernest Scott and Co., Fall River, Mass., recovers NaOH in form of a soln. ready for use, at a cost of $1\frac{1}{4}$ cents for each lb. of NaOH. The percentage of recovery is from 94 to 96. The above cost includes cost of labor, fuel, chemical and an allowance for interest and depreciation. The washing is done in such a way that a strong soln. of NaOH is obtained, and this is evapd. in a multiple-effect evaporator, using either live or exhaust steam. Plants which have operated for 16 years are still run with no unusual expense for maintenance.

W. F. FARAGHER.

Bleaching colored goods. TRAWDEN. *Textile World J.* 51, No. 17, 35-6(1916).—Small pieces of the fabrics dyed with bleaching colors should be treated by the usual methods in order to det. the effect upon the dyeings. Most of the dyes are sensitive to the action of the alkalis used in boiling off, but by regulating conditions, satisfactory results may be obtained. The goods should not be allowed to lie after removal from the chemick, and fresh chemick should be used. Methods for Turkey-red, indigo-blue and indanthrene dyeings are given.

W. F. FARAGHER.

Bleaching woolen and mixed goods. BERWICK. *Textile World J.* 51, No. 17, 35(1916).—Raw wool can be bleached by the bisulfite process. For a bath of 500 gal., use 12.5 gal. $NaHSO_3$ soln. of $32^\circ Tw.$ and 5 pints of H_2SO_4 . Keep the well scoured wool under the liquor, and allow it to remain overnight. In the morning, lift the wool, allow it to drain and then wash it thoroughly. For tinting, alkali violet C A may be used. Permanganate may be used also, but is expensive. For a 400 gal. bath, use 2 lbs. H_2SO_4 and 12 oz. $KMnO_4$. Enter 100 lbs. of scoured wool, and pole for $\frac{1}{4}$ hr. Lift the stock and place into a bath containing 1.5 gal. $NaHSO_3$ soln. of $32^\circ Tw.$ Do not allow the stock to remain in the $NaHSO_3$ soln. longer than is necessary to discharge the brown discoloration. Yarn and piece goods may be bleached by the same materials, and the latter also by means of SO_2 .

W. F. FARAGHER.

Terms used in the cotton industry. W. A. G. CLARK. U. S. Bur. Foreign and Dom. Commerce, *Special Agents' Series* No. 105, 22 pp.(Sept., 1915).—C. explains briefly the correct use of common terms including the various systems of cotton-yarn numbering, designation of various types of cloth, and the translation of foreign terms; 25 conversion tables applicable to the textile industry are included. F. W. S.

Systematic examination and testing of raw silk. K. B. LAMB. *Textile World J.* 51, No. 7, 209-15 (1916).—Inspection tests for quick detn. of certain qualities are regularly employed. They require, however, much skill and experience and are open to the objections applying to all subjective tests. The following qualities of the fibers are thus detd.: Color, cleanliness, luster, "feel," condition of gum, and uniformity. The diameter and crossings with lacings of skeins are learned by inspection. Inspection also reveals defects such as knots, loops, nibs, split ends, fine ends, coarse ends, double ends, corkscrews and roughness of fibers. Defects in the fibers are best observed by winding a single strand of raw silk upon a "mirror," a piece of black cardboard, 6 × 11 in. or 3 × 6 in. A diagram for securing representative sample skeins from the bale is given. Moisture is detd. in a regulation conditioning oven, the conditioned wt. being the dry wt. plus 11%. Loss during boiling off is detd. by making a skein of 100 g. by taking parts of ten skeins drawn from different books of the bale. The test skein is conditioned, and then boiled off, in 2 consecutive soap solns. containing 25% of soap calcd. on the wt. of the test skein. The loss is found by thorough washing, followed by conditioning. Tenacity and elasticity are important properties, and are obtained regularly by means of suitable dynamometric app. Winding tests are important, as they show the number of ends an operative can keep up. The test is made by winding dry 10 skeins at an av. rate of 75 or 150 yds. per min. The number of ends and breaks per 300,000 yds. is recorded. The test is also valuable in showing the amt. of waste to be expected. Microscopic tests are very important, but until recently have received but little attention in commercial practice. Photomicrographs are very useful. Much value should be derived by using the microscope in examn. of the raw and boiled-off fibers. The effects of the different processes during manufacture are also made evident by the proper use of the microscope.

W. F. FARAGHER.

Manufacture of artificial straw. RUTHVEN. *Textile World J.* 51, No. 12, 25-6 (Feb. 19, 1916).—Two- and three-thread tussah silk is generally used for straw for millinery braids, but for the softer, more yielding straws, trams, organzines and tsatlées are used. The threads are passed through gelatin soln. and are then squeezed. Excess H₂O is removed by means of currents of cold air from fans. The dried product is then wound upon spools and is ready for use. In some cases, the straw is crimped before spooling. A crinkled straw is obtained by only partially drying the straw from the gelatin vat. Glycerol gives a softer, more brilliant product. Ribbons are made by using tsatlée silk, drying with hot rolls and using gum tragacanth. This product is soft and is used for imitation willow plumes.

W. F. FARAGHER.

Quinone vat dyes. A. SCHMIDT. U. S., 1,175,997, Mar. 21. Alkali metal salts of leuco derivatives of quinone vat dyes, e. g., a dye derived from benzoquinone and *p*-chloroaniline, are dissolved in an aq. soln. of an alkali salt of sulfonated ricinoleic acid to obtain a prepn. for dyeing which is readily sol. in H₂O.

Sulfur dyes. M. BUFF and A. THAUSS. U. S., 1,175,230, Mar. 14. Leuco-indophenols derived from Et- α -naphthylamine or tetrahydro- α -naphthylamine and *p*-aminophenol, halogenated *p*-aminophenols, *p*-amino-*o*-cresol or dichloro-*p*-aminophenol are heated with Na₂S in boiling alc. for 70-80 hrs., the alc. is distd. off and the product is washed with hot H₂O and then with a boiling soln. of Na₂S. It is a dark blue powder dyeing cotton reddish blue from a hyposulfite vat.

Yellow-red safranin dyes. R. BURCKHARDT. U. S., 1,174,820, Mar. 7. Nitrosoethyl-*o*-toluidine and *m*-aminoethyl-*p*-toluidine are condensed together by heating with alc. and HCl, forming a product which dissolves in concd. H₂SO₄ with a green color turning to blue and then to red on the addition of H₂O and giving a yellow-red on cotton when printed or dyed with tannin as mordant. Methyl-*p*-toluylenediamine or ethyl-

p-toluylenediamine with methyl- (or ethyl-) *m*-toluylenediamine give a like product.

Apparatus for dyeing duck or canvas. L. J. MATOS. U. S., 1,175,538, Mar. 14.

Apparatus for dyeing in vats. J. J. TRACY. U. S., 1,174,912, Mar. 7.

Dyeing pelts, hair, feathers. F. MERKEL. U. S., 1,175,539, Mar. 14. A soln. formed of *m*-hydroxydiphenylamine and an oxidizing agent, *e. g.*, Na perborate is used, with a mordant of Na₂Cr₂O₇ and CuSO₄.

Indigo product for dyeing and printing. M. ILJINSKY. U. S., 1,175,634, Mar. 14. A leuco compd. of an alk. earth with indigo or other vat dye is combined with hyposulfite to form a product which is almost insol. in H₂O and is suitable for dyeing or printing.

Dyeing. F. GÜNTHER. U. S., 1,176,363, Mar. 21. A blue-black color is produced on fabrics by applying a condensation product of acetone with 1,8-naphthylenediamine-4-sulfonic acid and β -naphthol and then developing with diazotized *p*-nitroaniline.

Dyeing. J. CHESTER. Brit., 23,214, Nov. 28, 1914. Textile and like materials of animal origin are dyed by means of a bath containing constituents which interact to form HNO₂, together with a metallic salt, the bath being strongly heated. According to an example, a brown shade is produced on wool by immersing it in a bath of NaNO₂, Na₂Cr₂O₇, and H₂SO₄, and boiling; CuSO₄ gives a reddish brown color.

Dyeing. E. LODGE and J. M. EVANS. Brit., 23,386, Nov. 18, 1914. In the vat dyeing process described in 29,832, 1913 (*C. A.* 9, 1695) animal fibers, fur, feathers, and artificial silk may be included with the materials specified for treatment.

Dressing textiles dyed with vat colors. CASELLA & Co. Fr., 478,045, July 11, 1914. To the dressing of dextrin or glucose are added salts which prevent running in the hot alk. bath in which the finished material is washed.

Fireproofing textile materials. T. I. J. CRAIG and WHIPP BROS. & TODD. Fr., 477,857, Mar. 2, 1915. See Brit., 16,153 (*C. A.* 10, 98).

Applying designs to textiles. DRAKE PRINTING CO., A. MCKERROW, H. WALTON and G. E. SHEARSMITH. Fr., 477,822, Feb. 26, 1915. The design is printed on a transfer surface from which it is detached by heat. This transfer film is composed of an opaque layer covered with an adherent fusible layer which does not penetrate the opaque layer.

Protective treatment of silk for loading. SCHADD & KORTLING. Fr., 478,007, Mar. 12, 1915. Before concluding the operation of charging, the silk is treated with organic compds., particularly those containing N or S or both of these, which oxidize more readily than the fibroin, and, if necessary, whose first products of oxidation have still a reducing action, which change neither the feel nor the color of the silk, and which do not form with metallic salts undesirable colored compds.

26. PAINTS, VARNISHES AND RESINS.

A. H. SABIN.

Cellon and cellon varnish. ANON. *Elektrotechn. Z.* 37, 109(1916).—Cellon is a celluloid-like material made from acetylhydrocellulose and a neutral softening material. It is made in all forms and is not inflammable. For elec. purposes it is as good as hard rubber and not as brittle. By heating to 70–80° it may be bent and formed and, by painting with cellon varnish, it may be firmly cemented together. The disruptive voltage varies from 13,200 v. to 35,000 v. for thicknesses of from 0.2 to 2.0 mm. The varnish is proof against oils, fats, petroleum, benzene, acids and alkalis and is used as a non-corrosive paint.

W. E. RUDER

Wood flour (KRESSMANN) 18.

Paint. H. HACKL and H. BUNZEL. U. S., 1,175,751, Mar. 14. Freshly pptd. hydrated FeS is subjected to atm. oxidation to produce a pigment containing $\text{Fe}(\text{OH})_2$; free S is extd. with CS_2 or other solvent, and the residual pigment is mixed with oil or other usual paint vehicles.

Paint. N. B. ARNOLD. U. S., 1,175,110, Mar. 14. ZnO 300, SiO_2 75 and linseed oil about 60 parts are mixed to form a paint for use on surfaces exposed to the weather.

Carbon pigment from coal pitch. A. C. EVANS and P. J. MITCHELL. U. S., 1,175,632, Mar. 14. Hot coal pitch is washed with dil. NaOH or KOH soln., treated with solvent naphtha and heated to 100° , the finely divided C is allowed to settle and the liquid is decanted or filtered off and distilled to recover the naphtha.

Pellicles of oil and oil-paint. G. MÜLLER-NÄEGELI. U. S., 1,175,169, Mar. 14. A coat of oil-paint or varnish is spread on strong weakly-sized absorbent paper previously treated with an alk. silicate soln. to prevent permanent adhesion of the paint or varnish and the pellicle formed is stripped off the paper and may be attached to wood, textile fabric or other material by the surface which has been rendered somewhat sticky by the saponifying action of the alk. silicate soln.

Composition for painting ships' decks. A. DENNY and D. G. ANDERSON. Fr. 477,975, Mar. 10, 1915. The essential ingredients are, a mixt. of plaster of Paris and a small amt. of portland cement, in combination with a filling such as pumice, coke-breeze, amianthus, saw-dust, etc., and a dil. soln. of NaAlO_2 . Cf. C. A. 9, 2581.

Drying oils. BATAAFSCHE PETROLEUM MAATSCHAPPIJ. Brit., 23,376, Dec. 1, 1914. Drying oils are prepd. from the distn. products of mineral oils having b. p. of 220 – 260° , by forming in them unsatd. hydrocarbons by chlorinating and then removing HCl from the chlorinated products by heating with a catalyst such as Zn or other metal or a metal chloride. Cf. C. A. 9, 2602.

Paints and varnishes. H. TERRISSE and INDESTRUCTIBLE PAINT CO. Brit. 23,054, Nov. 25, 1914. Solubilized fossil resins, esterified with glycerol or high-boiling alcs. prepd. by the process of 23,055, 1914 (following pat.) are used with appropriate solvents in the production of varnishes, paints, and coating compns. Other resins may be added. Esterified manilla resin is melted, heated to 300° , and incorporated at that temp. with linseed oil, the temp. then being raised to 310° until the desired consistence is reached. Driers are added in the usual way, and the varnish is dild. with spirit, turpentine, etc. Another example described the production of a varnish from the glyceryl ester of Congo copal in a similar manner. A paint is prepd. by grinding the varnish prepd. as above described with ZnO . Cf. 14,554, 1903, and 23,039, 1908.

Resin esters. H. TERRISSE and INDESTRUCTIBLE PAINT CO. Brit., 23,055, Nov. 25, 1914. Esters are obtained from fossil resins by first converting the resin into a product sol. in linseed or other drying oil, and then heating this product with glycerol, linalool, or other alc. of high b. p., under pressure or not. Suitable resins are Congo copal, Zanzibar or Madagascar animé, kauri, Benguela copal, pontianac, manilla, etc. The solubilizing treatment may be effected by heating the resin, preferably under pressure, with or without solvents such as phenol, cresol, naphthalene, copal oil, or resin oil, as described in 14,544, 1903, and 23,039, 1908; or the fossil resins may be fused, solubilized by heating with copal oil, preferably copal oil which has been redistd. under reduced pressure, and then esterified by heating with glycerol, etc.; the solubilizing and esterifying processes may be carried out in one operation. The glycerol or other alc. is preferably used in excess of the theoretical amt.

Artificial phenolic resin. B. B. GOLDSMITH. U. S., Reissue 14,087, Mar. 14. See original pat., 1,168,626; C. A. 10, 826.

Bactericidal phenolic condensation products. A. HEINEMANN. U. S., 1,176,056, Mar. 21. A phenolic condensation product while in a heated fluid condition is mixed with cacodylic acid or other alkyl As compd. and the mixt. is stirred and heated until uniform. The product is adapted for use in painting surfaces exposed to sea water. Cf. C. A. 9, 3370.

27. FATS, FATTY OILS AND SOAPS.

E. SCHERUBEL.

The chemistry and analyses of fats in 1914. ANON. *Mat. grasses* 9, 4440-1 (1916).—A short review of progress. E. J. KELLEY.

Study of wool fat. A. DUBOSC. *Mat. grasses* 8, 4358-60 (1915).—D. gives the following figures as a result of his expts.: d. 0.997, m. 32°, liquefies 85°, acid no. 40.65, sapon. no. 246, I no. 93.69, mol. wt. 375-385, ash traces, H₂O 0.116%, saponifiable fatty acids (oleic) 54.037%, coloring matter traces. Cf. C. A. 10, 1104. E. J. K.

The hardening of fats through catalytic addition of hydrogen. G. FREDRICH. Univ. Bonn. *Arch. Pharm.* 253, 512-73 (1915).—The principal results of the investigation are summarized as follows: It is solely an assumption of Erdmann and his co-workers that reduction of Ni oxides in oil by means of H stops with the formation of a suboxide and that such suboxide acts as an H-carrier. The existence of a Ni suboxide is entirely problematical. Equally questionable are assumptions and assertions that hydrated Ni oxides are formed, or that Ni compds. in general can act as H-carriers. It has been demonstrated with certainty, not only through elec. cond. but also with the CO test, that metallic Ni results during the hardening of fats through application of Ni oxide and other Ni compds. Thus it has been shown that reduction of Ni oxide in oil by H does not stop at a suboxide but on the contrary progresses as in an ordinary dry reduction to the metal itself. It is certain that inability on the part of Erdman and co-workers to detect metallic Ni by means of elec. cond. was in the main due to contaminations of fatty acid salts of Ni and other products contained in the samples. examd. Thus, Siegmund and Suida failed to detect electrically a content of at least 48% Ni which according to their own analyses must have been present. Erdmann's explanation of the action of Ni oxides as given in a series of tests designed to be comparative cannot be regarded as a proof, since possibility for comparison is excluded under the varied conditions obtaining in metallic Ni reduced in oil and in the dry state. It must be regarded as proved that, in hardening fat by use of Ni^{II} oxide or Ni^{III} oxide and of Ni salts, the H-carrier is in reality metallic Ni freed from its compds. by the action of H. The statement: "No hardening of fat without free metal" is justified in view of the present state of the science and exact experimentation.

W. O. E.

Hydrolysis of some of the common vegetable oils. W. F. RUDD. *J. Am. Pharm. Assoc.* 5, 170-4 (1916).—A report of the results of expts. relating to the hydrolysis of several vegetable oils with an alkali. In 1 of the series of expts. the oils were treated with an alkali, in the 2nd with an enzyme and in the 3rd with both alkali and enzyme to det. if possible whether the relative sapon. factor will convey a knowledge of their relative digestibility. The number of expts. as recorded is considered to be altogether too small to warrant drawing any general conclusions and the work is to be continued.

M. I. W.

The viscosity of oils in the Redwood and the Ostwald viscosimeters. CHARLES A. SAVILL AND ARTHUR W. COX. *J. Soc. Chem. Ind.* 35, 151-3 (1916).—As a simple method for converting values for viscosities detd. by means of any of the viscosimeters in common use, such as the Redwood, to abs. values as detd. by the Ostwald U-tube

viscosimeter, the authors propose the following: Using pure phenol at 25° as the standard, det. the const. K for a particular Ostwald instrument by substituting in the formula $K = \eta/td$ when η = abs. viscosity, t = time of flow in seconds and d = density at 25°. Having K , det. the values of η for solns. of H_2SO_4 of various strengths at a given temp. and plot a curve with values of η as ordinates and percentages of H_2SO_4 as abscissas. Any instrument for technical use may then be calibrated by comparing the values obtained with similar solns. with those plotted. H. L. OLIN.

Utilization of sulfite liquor for washing purposes. K. LÖFFL. *Seifensieder-Ztg.* 42, 431-2(1915).—This by-product of the wood-pulp industry can be used by the soldiers in the field by making it into a paste with kieselguhr or fine sand. The addition of 1 to 2% of Na_2CO_3 increases its deterative powers. By adding 2% of crude cresol to the liquor it makes an excellent agent for killing body lice, and by incorporating 10% cresol it makes a good and cheap cleanser and disinfectant for floors. E. SCHERUBEL.

Marseilles soaps. J. DAVIDSOHN. *Seifensieder-Ztg.* 42, 432-3(1915).—These soaps are green or white; the former is used in the textile industry and the latter as a household and children's soap. Analysis shows the latter to be made from 35% palm-kernel or coconut oil, 40% olive and 25% cottonseed oil. The green soap is made from green sulfonated oil with small amts. of palm-kernel, peanut, sesame and cottonseed oils. E. SCHERUBEL.

American floating soap. E. SCHUCK. *Seifensieder-Ztg.* 42, 410-2(1915).—These soaps are made on a formula of from 25 to 30% of cocoanut oil and the balance edible tallow. The kettle practice for this product consists in thorough sapon., graining and washing, followed by a strong lye boil, and then by further washing and graining and finally settling. To make the soap float air is worked into it by means of a crutch whose agitator makes 160 revolutions per min. The time necessary is from 15 to 20 mins. E. SCHERUBEL.

Casein and its use in milled soaps. E. H. D. *Seifensieder-Ztg.* 42, 472-3(1915).—This product is considered a filler, although it is said to be beneficial to the skin. It must first be put into soln. by means of alkali. A good formula for a casein soap is soap 400, borax 1, casein 35, 38° Bé. lye 2, hot H_2O 20 and cold H_2O 90 parts. E. SCHERUBEL.

Production of rosin in Prussia. W. STORANDT. *Seifensieder-Ztg.* 43, 149(1916).—Austria is now producing her own rosin and the quality is the same as that produced in France and the U. S. Prussia has taken steps to provide her own supply. Cf. C. A. 9, 2459. E. SCHERUBEL.

Calculation of yields for soaps. O. BANNINGER. *Seifensieder-Ztg.* 43, 73-4, 98-9, 121-2(1916).—Lengthy discussion of rather simple calcns. E. SCHERUBEL.

Manufacture of half boiled, filled soaps. E. H. D. *Seifensieder-Ztg.* 42, 453-4 (1915).—These soaps contain rosin, tallow and palm-kernel oil and are filled with Na_2SiO_3 soln. E. SCHERUBEL.

Sugar soaps. W. KIND. *Seifensieder-Ztg.* 43, 143-6(1916).—K.'s conclusions with regard to the use of sugar in soaps are: The value of a soap is detd. by the relation of its washing power to its degree of injuriousness. The deterative value of soap is not dependent upon its chem. analysis. If one does not consider free alkali as having deterative power it must be viewed as forming absorption combinations. The chem. deterative action of free alkali and also its injurious action upon color and fiber depend upon its hydroxyl ion concn. The non-dissociated alkali sucate has as little deterative action as raw sugar. The addition of free alkali to soap followed by neutralization with sugar is based upon false considerations. The addition of sugar to soap is a disadvantage because of lessened lathering properties and deterative powers. R. S.

Mineral-oil soaps. ANON. *Seifenfabrikant* 36, 125-7(1916).—Discussion regarding the possibility of using the alkali salts of the naphthenic acids as substitutes for soap. E. SCHERUBEL.

Japan wax in the soap industry. P. N. *Seifensieder-Ztg.* 43, 74-5(1916).—Owing to the high price of other raw materials this product is now in line as regards price and may be used to replace tallow which it resembles except that its titer is much higher, 53-37 degrees. A number of formulas are given in which Japan tallow is used to the extent of from $\frac{1}{3}$ to $\frac{2}{3}$ of the fat. E. SCHERUBEL.

Japan wax. G. J. FELS. *Seifenfabr.* 36, 141-2(1916).—This substitute consists chiefly of palmitic and Japan acids. There is also 8% of sol. fatty acids. The Japan acid is dibasic and its K salt is difficultly sol. in H_2O and alc. Its formula is $C_{20}H_{40}(COOH)_2$. There are no diglycerides in Japan wax and its high glycerol content (10-14%) may be attributed to its low fatty acids and dibasic acid. E. S.

Lubricants for metals (BLAIR) 9. The fat of nux vomica (WATT) 17.

Hydrogenating oils and fats. C. ELLIS. U. S., 1,174,245, Mar. 7. Unsaturated oils and fats are hydrogenated by heating with water gas or H under pressure, using a catalyst of active charcoal coated with Pt or Ni.

Catalytic hydrogenation. H. K. MOORE. Brit., 22,980, Nov. 24, 1914. In the hydrogenation of unsaturated fats, fatty acids, fatty acid esters, hydrocarbons, etc., by passing the compound and H through a body of catalytic material, the catalyst is revived and freed from adhering oil, etc., by passing therethrough a stream of H at high velocity; the body of catalyst is preferably subjected in repeated succession to the action of H and the compound treated and to H alone at high velocity; the compound treated is preferably atomized by H under pressure.

Hydrogenating oils and fats. W. D. RICHARDSON. U. S., 1,175,905, Mar. 14. An electric arc is produced between Ni electrodes immersed in ether or other volatile liquid capable of dissolving fats to disintegrate a portion of the Ni and suspend it in the liquid. The suspension is mixed with the oil or fat to be hydrogenated and after hydrogenation is effected the volatile solvent is removed by distillation. Cf. C. A. 9, 2821.

Sulfonated stearic compound for use in emulsifying oils, waxes or fats. I. LEVINSTEIN. U. S., 1,176,378, Mar. 21. Stearic acid and a fat or fatty oil are treated with H_2SO_4 at 30-50°.

Wax, grease. J. B. HALL. Brit., 22,870, Nov. 21, 1914. A block of wax, paraffin, grease or other fusible material is formed with vertical grooves or perforations a, a^1 connected by a groove a^2 across the bottom, so that on partly melting the block, the lower melted portion may be poured off. The block is fitted into a container C which may have a spout c . The walls of the grooves a, a^1 may be lined with perforate or imperforate sheet metal, wood, or paper B .

29. LEATHER AND GLUE.

LYOYD BALDERSTON.

The importance and use of artificial tanning materials. J. PARSSLER. *Collegium* 1916, 1-4; *Chem. Ind.* 39, 15-20(1916); *J. Am. Leather Chem. Assoc.* 11, 162-3(1916).—The preparation and uses of neradol are described (cf. C. A. 7, 3853, 4092). The relatively

greater increase in the prices of vegetable tanning materials makes wider use of *neradol* advisable in Germany. L. B.

The action of salts of hydroxy acids upon chrome tanning. H. R. PROCTER AND J. A. WILSON. *J. Soc. Chem. Ind.* 35, 3, 156-9(1916).—Theoretically, chrome tanning will take place if the basicity and concn. of the Cr salt are properly regulated. In reality, certain very basic liquors fail to tan skins. Investigation has revealed that the presence of salts of many, if not all, of the hydroxy acids influences the tanning power of Cr salts. Expts. were made with Rochelle salt. If much of this salt be added to a chrome liquor, it loses its power to tan. Immediately after Rochelle salt has been added to a chrome liquor, a ppt. is given if the liquor is rendered alk., but this ppt. slowly redissolves. This is accounted for by the fact that the presence of hydroxy compds. prevents the pptn. of the metals as hydroxides. From a prepd. chrome liquor, a series of 8 solns. were prepd. varying in concn. of Rochelle salt from 50 g. per l. in soln. No. 1 to none in soln. No. 8. A piece of neutral calf skin was placed in each soln. for 24 hrs. The skins varied from bluish in No. 1 to green in No. 8. The skin in No. 1 was very full and soft, the others less so down to No. 8. All skins were tanned save No. 1 and No. 2. Upon adding 150 cc. per l. of $N Na_2CO_3$ to each liquor, No. 1 gave no ppt., No. 2 a light ppt. and all others heavy ppts. After 4 hrs. the skin in No. 2 was tanned. Two portions more (300 cc. per l. in all) of $N Na_2CO_3$ were added to No. 1. There was still no ppt. and after 48 hrs. the skin was not tanned. It was then washed and placed in fresh chrome liquor and tanned in a few hrs. The effect of the salt was upon the chrome rather than upon the skin. Apparently identical results were obtained by repeating the above expts. with neutral Na citrate, using equiv. concns. The Na salts of lactic, gallic, and salicylic acids prevent the pptn. of Cr in slightly alk. solns. As to possible sources of these compds. in chrome liquor, it is considered that they might be formed in quantities sufficient to prevent tanning by reducing the dichromate with impure sugars, or by reducing under improper conditions. Reducing dichromate at as low a temp. as possible with com. dextrin was tried. A piece of skin immersed in the resulting liquor tanned with difficulty. In order to ensure the production of a satisfactory chrome liquor by reducing dichromate with sugars, it is necessary to use reasonably pure sugar, and conditions giving satisfactory results should be closely adhered to. Although sugars are hydroxy compds., an excess of sugar, even to 20%, does not prevent tanning. This is explained in a detailed consideration of the action of Rochelle salt in forming metallic complexes. Rochelle salt has the power to strip chrome leather of its chrome, leaving it in an untanned condition. This information may be of value to manufacturers wishing to produce split leathers tanned with quebracho or mimosa bark. The skins may be chrome-tanned, then split, and then stripped of chrome, washed, and retanned as desired. Rochelle salt might be used to remove or prevent so-called salt stains, since hydroxy compds. form complexes with other metals including iron. Iron stains might be prevented by treatment with Rochelle salt before liming. For some kinds of leather, a bath in Rochelle salt might be preferable to pickling. Small amts. of Rochelle salt might produce the fullness and softness now produced through an excess of glucose. "Case-hardened" chrome leathers may be stripped and retanned. Also chrome cuttings and shavings may be stripped of chrome and made into glue stock. In stripping, the soln. must not contain a strong acid. The use of Rochelle salt for stripping might be made practical if the salt and chrome could be recovered. This may be effected to a large extent by the addition of H_2SO_4 to neutralize the equiv. of soda and reconstitute the $K H$ salt, which is very sol. and crystallizes out, so it can be sepd. and used again with a suitable addition of soda; while the chrome can be pptd. from the mother liquor as Cr hydroxide. Either crude $K H$ tartrate dissolved with soda, or a mixt. of equiv. amts. of lactic acid and Na_2CO_3 would be a cheap source of Rochelle salt. J. S. ROGERS.

Colloid chemistry and the glue industry. E. SAUER. Memmingen i/B. *Kolloid-Z.* 17, 130-5 (1915).—A brief outline of the glue-making process, followed by suggestions as to the use of colloidal chemical methods. Viscosity measurements are invaluable in controlling the process. The chemical changes in the process of glue boiling should be studied as colloidal phenomena.
H. I. MATTILL.

Shoe- and leather-blackening. J. BURSK. U. S., 1,174,308, Mar. 7. Ivory black 32, molasses 40 and neat's-foot oil 2 parts are mixed to form a blackening for leather.

Preserving fresh hides. J. H. YOCUM. U. S., 1,175,495, Mar. 14. Fresh hides are preserved, before tanning, by treatment with a mixt. of NaCl 97 and Na₂SO₃ 3%. Cf. C. A. 9, 2724.

Dressing hides and purifying tanning extracts electrolytically. B. SCHWERIN. U. S., 1,174,903, Mar. 7. Tanning ext. to be used and purified is confined between a diaphragm formed of parchment paper or other material permeable to basic substances and a leather diaphragm permeable to acids and tannin; an elec. current is passed from the anode to the cathode and through a hide which is suspended between the leather diaphragm and an anodic diaphragm of material, e. g., parchment paper, which is permeable to acids but not to tannin.

Gelatin composition as a substitute for leather and rubber. B. KEPNER. U. S., 1,174,734, Mar. 7. A woven fabric is treated with a soln. formed of glycerol 12-25, gelatin 100, French degreas or linseed oil 12-25 and tannin 6-12 parts and exposed to sunlight at a temp. of 50° or lower, treated with H₂O to render it more soft and flexible and finally while still moist is treated with oil.

Tanning apparatus. E. WILSON. U. S., 1,176,633, Mar. 21. The hides to be tanned are held in a rotating drum dipping into the vat of tanning liquor.

Tanning, impregnating. ELEKTRO-OSMOSE AKT.-GES. (GRAF SCHWERIN-GES.). Ger., 286,678, Jan. 8, 1914. Addition to 283,285 (C. A. 9, 2354). According to the principal process, the liquid containing the active substances, in which the material under treatment is immersed, is subjected, between diaphragms, to the action of the elec. current. Experience has shown that tannin exts. which, on account of the great number of non-tanning constituents contained therein, cannot be employed directly for tanning, are nevertheless applicable for elec. tanning if the osmotic tanning process is combined with an osmotic process of purifying the tannin ext. In carrying out this modified process, the app. specified in 283,285 is used, with this difference, that the chamber containing the tanning soln. is divided by means of a positive diaphragm, such as a piece of leather. All compartments are then filled, first, with H₂O, up to the chamber between cathode and the selected diaphragm, in which the tannin ext. is placed. Upon the passage of the current, all basic impurities of the ext. pass through the cathode diaphragm into the cathode chamber, while the acid impurities, which for most part are not so numerous as the basic, pass through the positive diaphragm into the subdivided H₂O-filled chamber, whence they pass through the skin and finally through the anode diaphragm into the anode chamber. When a certain preliminary purification has been effected in this manner, the tannin begins to pass through the positive diaphragm and to collect in the subdivided chamber between the positive diaphragm and the skin. The tanning process, as specified in 283,285, thereupon progresses. The tannin not used for tanning passes through the skin and collects in the chamber between the skin and anode, since it cannot pass through the anode diaphragm (weakly negative parchment paper).

Machine for working pelts, hides, and leather. L. RICHTER. Ger., 286,516, Mar. 21, 1914.

Removing glue from bone material, by steaming. O. RUF. Ger., 286,100, May 12, 1914. The bone material is removed, once or oftener, from the steamers during the extn. process, and subjected, immediately upon such removal, while still hot, to compression until the completely extd. bone material, by the last compression, assumes the form of a solid cake or briquet. The pressure is increased as the glue is removed. A suitable app. is shown.

Glue. R. BERLINER. U. S., 1,176,644, Mar. 21. Bones containing fatty matter are treated with gaseous SO_2 , freed from fat by extn. with benzine and then boiled to ext. glue.

30. RUBBER AND ALLIED SUBSTANCES.

R. T. STOKES.

Vulcanization accelerators. K. GORTLOB. *Gummi-Ztg.* 30, 303-8, 326-36(1916).—After reviewing the subject from an historical point of view, G. sets forth the virtues of "Vulkasit," a prepn. manufactured by the Bayer Co. G. claims to have shown that the prejudices of experienced rubber men, that 10% of S is necessary for proper vulcanization, are exploded. Very little is said concerning the compn. of "Vulkasit" other than that it is an org. base with a dissociation const. between 10^{-8} and 10^{-9} . E. L. D.

Process for the reclaiming of mixed cloth and rubber scrap. T. SCHOPFER. *Gummi-Ztg.* 30, 325(1916).—The waste is treated with a solvent for cellulose such as ammoniacal CuO , and devulcanized in the usual manner. The process is not new, but has not been adopted because of the difficulty of removing the solvent. E. L. D.

Reclaiming rubber waste. A. H. KING. *Mel. Chem. Eng.* 14, 309-11 (1916).—K. classifies rubber waste as (1) fabric-free, (2) fabric-bearing, (3) ebonite. The method of reclaiming differs with each class. The first method consists in softening and depolymerizing the scrap, after which the finely ground material is mixed with vaseline, tar, phenol, heavy mineral oil or rosin, and heated in steam at $300-375^\circ \text{F}$. for 6-48 hrs. In the 2nd class the fabric is separated from the rubber by one of 4 treatments, viz., (1) mechanical, (2) acid, (3) alkali, (4) solution, all of which are described in detail. E. J. K.

Analysis, purification and qualitative reaction of isoprene (OSTROMUISLENSKII) 10. New methods of obtaining divinyl, isoprene, etc. (OSTROMUISLENSKII) 10.

Diolefins (isoprene), caoutchouc. H. STERN. Fr., 477,956, July 9, 1914. Fuming H_2SO_4 is added, with cooling, to a mixt. of an aliphatic ketone with an alc. or ether, and the acid mixt. is heated. E. g., unsatd. hydrocarbons, especially C_5H_4 and its homologs, are passed through a heated mixt. of ketones and fuming H_2SO_4 containing anhydride (especially acetone and said acid). Modifications are specified.

Filler for automobile tires. F. A. HAGER. U. S. 1,174,856, Mar. 7. A mixt. formed of corn oil 24 lbs., S chloride 6 lbs., MgO 17.5 oz. and Venetian red 3 oz. is used.

Leather- and rubber-substitute for forming sheets. J. S. CAMPBELL. U. S., 1,174,967, Mar. 14. Comminuted leather 500, is mixed with an animal fat or fatty oil 30-40 parts, and heated with sufficient NaOH to effect saponification. Then hair, vegetable fiber or other fibrous material is added and the mixt. is blended with French chalk 25, CaO 10 and rubber or other vulcanizable gum 75 parts; all the ingredients are heated together, dried, rolled into sheets and vulcanized with S. Tannic acid, $\text{K}_2\text{Cr}_2\text{O}_7$, and borax may also be added in small amts.

TABLES OF PROPERTIES

of over Fifteen Hundred Common Inorganic Substances

By Wilhelm Segerblom, A.B., Instructor in chemistry at The Phillips Exeter Academy, Exeter, N. H. An indispensable reference book for chemists, manufacturers, and science teachers. Gives common names, chemical and physical properties, and solubilities of common chemicals. 8vo, x + 144 pages. Cloth. \$3.00 (prepaid).

Also FIRST YEAR CHEMISTRY, a modern elementary text by the same author. Cloth. \$1.50 (prepaid).

Specimen pages of either book sent FREE upon request.

plies used in Chemical and Met-
allurgical operations.

Wanted—Back Numbers

of the

American Chemical Society Journals

The Society is anxious to complete certain volumes of its publications which are nearly exhausted, and for which there is a heavy demand.

The Society will Buy.

The amount indicated is offered for the publications named, subject to withdrawal without notice. Only those listed below are desired.

Journal American Chemical Society.

- Vol. 17; Nos. 1, 5, 8 and 9, 75 cents each.
- Vol. 17; Nos. 2, 3 and 4, \$1.00 each.
- Vol. 18; No. 5, \$1.25; No. 8, 50 cents.
- Vol. 19; Nos. 1 and 4, 75 cents each.
- Vol. 19; Nos. 2, 3, 5, 7, 8 and 11, 50 cents each.
- Vol. 20; No. 3, 75 cents; Nos. 4, 8, 10 and 11, 50 cents each.
- Vol. 21; No. 12, 25 cents.
- Vol. 22; Nos. 3, 4, 9, 10, 11 and 12, 50 cents each.
- Vol. 37; No. 12, 25 cents.
- Vol. 38 (present year); Nos. 1, 2 and 3, 25 cents each.

Chemical Abstracts.

- Vol. 1; No. 2, 50 cents.
- Vol. 1; Nos. 3, 12, 13, 14, 15 and 16, 25 cents each.
- Vol. 10 (present year); Nos. 1, 2, 3 and 4, 25 cents each.

Journal Industrial and Engineering Chemistry.

- Vol. 14; Nos. 5, 6 and 7, 50 cents each.
- Vol. 6; Nos. 5, 6, 7 and 8, 25 cents each.
- Vol. 7; No. 1, 25 cents.
- Vol. 8 (present year); Nos. 1 and 2, 25 cents each.

Libraries and members of the Society are urgently requested to examine their files for extra numbers mentioned above.

Publications are to be sent carriage-free to the Secretary and must be received in good condition.

All communications and Journals should be addressed to

CHARLES L. PARSONS, *Secretary,*
Box 505, Washington, D. C.
